FIG. **2**G provides two supports as provided in FIG. **2**F such that at least two support members **292**, **294** may be connected to support structure wire **200** in multiple locations and collection fibers **130** may be connected between each end of the support structures. Collection fibers **130** may be connected between each end of a single support structure and between multiple support structures. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support structure wire **200**.

FIG. **3** provides a schematic diagram of storing circuit **300** for storing energy collected by one or more collection devices (**130** from FIG. **2**). Load **150** induces current flow. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. A plurality of diodes may be placed at any position in the circuit. Switch **330** may be electrically connected between load **150** and at least one collection device (**130** from FIG. **2**) to connect and disconnect the load. Capacitor **320** maybe connected in parallel to the switch **330** and load **150** to store energy when switch **330** is open for delivery to load **150** when switch **330** is closed. Rectifier **340** may be electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. Rectifier **340** may be a full-wave or a half-wave rectifier. Rectifier **340** may include a diode electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. The direction of the diode of rectifier **340** is optional.

In an exemplary embodiment provided in FIG. **4**, storage circuit **400** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **410**. If charging capacitor **410** is not used, then the connection to ground shown at capacitor **410** is eliminated. A plurality of diodes may be placed at any position in the circuit. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. Diode **440** may be placed in series with load **150**. The voltage from capacitor **410** can be used to charge spark gap **420** when it reaches sufficient voltage. Spark gap **420** may comprise one or more spark gaps in parallel. Non-limiting examples of spark gap **420** include mercury-reed switches and mercury-wetted reed switches. When spark gap **420** arcs, energy will arc from one end of the spark gap **420** to the receiving end of the spark gap **420**. The output of spark gap **420** may be electrically connected in series to rectifier **450**. Rectifier **450** may be a full-wave or a half-wave rectifier. Rectifier **450** may include a diode electrically connected in parallel to transformer **430** and load **150**, between the receiving end of spark gap **420** and ground. The direction of the diode of rectifier **450** is optional. The output of rectifier **450** is connected to transformer **430** to drive load **150**.

FIG. **5** presents motor driver circuit **500**. One or more collection devices (**130** from FIG. **2**) are electrically connected to static electricity motor **510**, which powers generator **520** to drive load **150**. A plurality of diodes may be placed at any position in the circuit. Motor **510** may also be directly connected to load **150** to drive it directly.

FIG. **6** demonstrates a circuit **600** for producing hydrogen. A plurality of diodes maybe placed at any position in the circuit. One or more collection devices (**130** from FIG. **2**) are electrically connected to primary spark gap **610**, which may be connected to secondary spark gap **640**. Non-limiting examples of spark gaps **610**, **640** include mercury-reed switches and mercury-wetted reed switches. Secondary spark gap **640** may be immersed in water **630** within container **620**. When secondary spark gap **640** immersed in water **630** is energized, spark gap **640** may produce bubbles of hydrogen and oxygen, which may be collected to be used as fuel.

FIG. **7** presents circuit **700** for driving a fuel cell. A plurality of diodes may be placed at any position in the circuit. Collection devices (**130** from FIG. **2**) provide energy to fuel cell **720** which drives load **150**. Fuel cell **720** may produce hydrogen and oxygen.

FIG. **8** presents exemplary circuit **800** for the collection of energy. Storage circuit **800** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **810**. If charging capacitor **810** is not used, then the connection to ground shown at capacitor **810** is eliminated. A plurality of diodes may be placed at any position in the circuit. The voltage from capacitor **810** can be used to charge spark gap **820** when it reaches sufficient voltage. Spark gap **820** may comprise one or more spark gaps in parallel or in series. Non-limiting examples of spark gap **820** include mercury-reed switches and mercury-wetted reed switches. When spark gap **820** arcs, energy will arc from one end of spark gap **820** to the receiving end of spark gap **820**. The output of spark gap **820** may be electrically connected in series to rectifier **825**. Rectifier **825** may be a full-wave or a half-wave rectifier. Rectifier **825** may include a diode electrically connected in parallel to inductor **830** and load **150**, between the receiving end of spark gap **820** and ground. The direction of the diode of rectifier **825** is optional. The output of rectifier **825** is connected to inductor **830**. Inductor **830** may be a fixed value inductor or a variable inductor. Capacitor **870** may be placed in parallel with load **150**.

FIG. **9** presents a flow diagram of a method for collecting energy. In block **910**, one or more collection devices may be suspended from a support structure wire. In block **920**, a load may be electrically connected to the support structure wire to draw current. In block **930** a diode may be electrically connected between the support structure wire and the electrical connection to the load. In block **940**, energy provided to the load may be stored or otherwise utilized.

A windmill is an engine powered by the energy of wind to produce alternative forms of energy. They may, for example, be implemented as small tower mounted wind engines used to pump water on farms. The modern wind power machines used for generating electricity are more properly called wind turbines. Common applications of windmills are grain milling, water pumping, threshing, and saw mills. Over the ages, windmills have evolved into more sophisticated and efficient wind-powered water pumps and electric power generators. In an example embodiment, as provided in FIG. **10**, windmill tower **1000** of suitable height and/or propeller **1020** of windmill tower **1000** may be equipped with energy collecting fibers **1030**, **1040**. Collecting fibers **1030**, **1040** may turn windmill **1000** into a power producing asset even when there is not enough wind to turn propellers **1020**. During periods when there is enough wind to turn propellers **1020**, collecting fibers **1030**, **1040** may supplement/boost the amount of energy the windmill produces.

Windmill **1000**, properly equipped with ion collectors **1030**, **1040**, such as non-limiting example carbon fibers, can produce electricity: 1) by virtue of providing altitude to the carbon fiber to harvest ions, and 2) while the propeller is turning, by virtue of wind blowing over the carbon fiber producing electricity, among other reasons, via the triboelectric effect (however, it is also possible for the triboelectric effect to occur, producing electricity, in winds too weak to turn the propeller).

There are at least two ways that energy collectors may be employed on or in a windmill propeller to harvest energy. Propellers **1020** may be equipped with energy collectors **1030**, **1040** attached to, or supported by, propeller **1020** with wires (or metal embedded in, or on propeller **1020**) electrically connecting energy collectors **1030**, **1040** to a load or power conversion circuit. There may be a requirement to electrically isolate energy collectors **1030**, **1040**, which is added to propeller **1020**, from electrical ground, so that the energy collected does not short to ground through propeller **1020** itself or through support tower **1010**, but rather is conveyed to the load or power conversion circuit. Energy collectors may be connected to the end of propellers **1020** such as collectors **1030**. Alternatively, energy collectors may be connected to the sides of propellers **1020** such as collectors **1040**.

Alternatively, propeller **1020** may be constructed of carbon fiber or other suitable material, with wires (or the structural metal supporting propeller **1020** may be used) electrically connecting to a load or power conversion circuit. In the case of propeller **1020** itself being constructed of carbon fiber, for example, the fiber may be 'rough finished' in selected areas so that the fiber is "fuzzy." For example, small portions of it may protrude into the air as a means of enhancing collection efficiency. The fuzzy parts of collectors **1030**, **1040** may do much of the collecting. There may be a requirement to electrically isolate carbon fiber propeller **1020** from electrical ground, so that the energy it collects does not short to ground through metal support tower **1010**, but rather is conveyed to the load or power conversion circuit. Diodes may be implemented within the circuit to prevent the backflow of energy, although diodes may not be necessary in some applications.

In an alternative embodiment, windmill **1000** may be used as a base on which to secure an even higher extension tower to support the energy collectors and/or horizontal supports extending out from tower **1010** to support the energy collectors. Electrical energy may be generated via ion collection due to altitude and also when a breeze or wind blows over the collectors supported by tower **1010**.

Any process descriptions or blocks in flow charts should be understood as representing modules, segments, or portions of code which include one or more executable instructions for implementing specific logical functions or steps in the process, and alternate implementations are included within the scope of the preferred embodiment of the present disclosure in which functions may be executed out of order from that shown or discussed, including substantially concurrently or in reverse order, depending on the functionality involved, as would be understood by those reasonably skilled in the art of the present disclosure.

It should be emphasized that the above-described embodiments of the present disclosure, particularly, any "preferred" embodiments, are merely possible examples of implementations, merely set forth for a clear understanding of the principles of the disclosure. Many variations and modifications may be made to the above-described embodiment(s) of the disclosure without departing substantially from the spirit and principles of the disclosure. All such modifications and variations are intended to be included herein within the scope of this disclosure and the present disclosure and protected by the following claims.

Therefore, at least the following is claimed:

1. A method of collecting energy comprising:

suspending at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment from a windmill, the at least one collection device electrically connected to the windmill; and

providing a load with an electrical connection to the at least one collection device to draw current.

2. The method of claim **1**, wherein the collection device collects energy by triboelectric effect.

3. The method of claim **1**, wherein the collection device comprises a collection fiber.

4. The method of claim **1**, wherein the collection device comprises a diode and a collection fiber and the diode is electrically connected between the collection fiber and the load.

5. The method of claim **1**, further comprising storing energy provided to the load.

6. The method of claim **5**, wherein storing energy provided to the load comprises storing energy in a capacitor or an inductor.

7. The method of claim **3**, wherein the collection fiber comprises carbon fiber or graphite fiber.

8. A system of energy collection comprising:

a windmill;

at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment electrically connected to the windmill; and

a load electrically connected to the at least one collection device.

9. The system of claim **8**, wherein the collection device collects energy by triboelectric effect.

10. The system of claim **8**, wherein the collection device comprises a collection fiber.

11. The system of claim **8**, wherein the collection device comprises a collection fiber and a diode electrically connected between the load and the collection fiber.

12. The system of claim **9**, wherein the diode is elevated relative to the ground level.

13. The system of claim **10**, wherein the collection fiber comprises a carbon fiber or a graphite fiber.

14. The system of claim **8**, further comprising a diode electrically connected between the at least one collection device and the support structure.

15. The system of claim **8**, further comprising: a switch connected in series between the at least one collection device and the load; and a capacitor connected in parallel with the switch and the load.

16. The system of claim **15**, wherein the switch comprises an interrupter connected between the plurality at least one collection device, and wherein the interrupter comprises at least one of a fluorescent tube, a neon bulb, an AC light, and a spark gap.

17. The system of claim **8**, further comprising: a motor for providing power, the motor connected between the at least one collection device and the load; and a generator powered by the motor.

18. The system of claim **8**, further comprising a fuel cell between the support structure and the load.

19. The system of claim **18**, wherein the fuel cell produces hydrogen and oxygen.

20. A system of collecting energy comprising:

means for suspending at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment from a windmill structure, the at least one collection device electrically connected to the means for suspending;

means for inducing current flow, the means for inducing current flow electrically connected to the means for suspending; and

means for restricting the backflow of charge carriers, the means for restricting the backflow of charge carriers electrically connected between the at least one collection device and the means for inducing current flow.

APPARATUS FOR DETECTING CHANGES IN THE ATMOSPHERIC ELECTRIC FIELD

Lothar H. Ruhnke, Minneapolis, Minn., assignor to Litton Systems, Inc., Beverly Hills, Calif.

Filed Dec. 20, 1963, Ser. No. 332,186
4 Claims. (Cl. 325—113)

This invention relates to a cloud detector or an apparatus for sensing electrostatic conditions in the earth's atmosphere.

Cloud detection apparatus which is presently employed is usually of the "ceilometer" type which merely measures the height of the lower surface of the clouds to indicate the ceiling conditions. One object of the present invention is to determine the location of both the top and the bottom of one or more cloud formations of the atmosphere.

While electrostatic sensors of one type or another have been proposed heretofore for use in the atmosphere, they have been so complex and expensive that they have not enjoyed widespread use. In addition, cloud radars have recently been developed, but their usefulness is limited by failures when different zones of the atmosphere contain droplets of different sizes, as discussed more fully below. Accordingly, it is another object of the present invention to simplify and reduce the cost of cloud detectors, while maintaining reliability, compatibility with existing equipment, and adequate sensitivity for all practical purposes.

In accordance with an illustrative embodiment of the present invention, a conventional U.S. Weather Bureau or U.S. Army meteoroligical radiosonde transmitter may be provided with a modulator which is controlled by a field effect transistor. The input to the field effect transistor is a dipole antenna. Each of the arms of the dipole antenna may be five to fifty feet in length, for example, and one of the dipole elements may trail the radiosonde package while the other element may extend forward in the direction of movement of the unit. When a balloon is employed to carry the cloud detector unit aloft, a weight may be attached to one of the antenna elements so it hangs below the instrument package, while the other antenna element can extend along, or even form the flexible connection between the radiosonde unit and the balloon. A receiving unit is provided to pick up the modulated signals from the radiosonde apparatus, demodulate these signals and record them. While it is contemplated that the receiver may normally be situated on the ground and receive signals from a rising radiosonde unit, the radiosonde unit could well be employed by an aircraft to determine conditions below a cloud layer. Under these conditions the receiver would be mounted on the plane and the radiosonde unit could be parachuted to the ground.

In accordance with a feature of the present invention, therefore, a system for detecting electrostatic field conditions in the atmosphere includes a transmitter, arrangements for moving the transmitter through the atmosphere, an antenna extending a substantial distance from the transmitter, and a field effect transistor connected to receive electrostatic input signals from said antenna and to modulate the output of the transmitter in accordance with voltages detected by the antenna.

In accordance with one aspect of the present invention, simplicity of circuitry and stability of operation are achieved by the use of dynamic circuitry which measures the instantaneous difference in potential between two antenna elements. Thus, a high input resistor may be connected between the input antenna elements. With this type of arrangement the instrument package must be continuously moved through the atmosphere in order to

give meaningful results. Under these conditions, the recorded output indicates changes in electric fields. A constant electric field, corresponding to a linear change in potential produces no substantial output signal. It has been determined that a balloon velocity of about five meters per second will produce good results with a dipole antenna shunted by a 1,000 megohm resistor and connected to a field effect transistor as discussed in detail in the present specification. With lower velocities, a higher input impedance or greater amplification would be required, with higher velocities, such as rocket propulsion or the like, permitting even lower input impedances and simpler input circuits.

Accordingly, it is a feature of the invention that apparatus is provided for moving a radiosonde unit through the atmosphere at a predetermined rate, that two element input antenna preferably of the dipole type is provided, and that the antenna is connected to the radiosonde by simple dynamic amplification circuitry, which requires continuous movement of the apparatus to give useful output information.

The novel features which are believed to be characteristic of the invention both as to its organization and method of operation, together with further objects and advantages thereof, will be better understood from the following description considered in conjunction with the accompanying drawings in which a typical embodiment of the invention is illustrated by way of example. It is to be expressly understood, however, that the drawings are for the purpose of illustration and description only and are not intended as a definition of the limits of the invention.

In the drawing:

FIG. 1 is a schematic block diagram of a radiosonde equipment for sensing changes in the electric field of the atmosphere, and thus detecting clouds, in accordance with the present invention;

FIG. 2 is a diagrammatic showing of the record obtained under typical cloud conditions; and

FIG. 3 is a circuit diagram indicating a typical arrangement of connections of a dipole antenna, a field effect transistor, and the input terminals of a standard meteorological radiosonde apparatus.

With reference to the drawings, FIG. 1 shows a radiosonde package **12** supported by a balloon **14**. The radiosonde unit includes a transmitter **16**, blocking oscillator **18**, pressure sensor **20**, and a field effect transistor unit **22**. A dipole antenna having an upper element **24** and a lower element **26** is connected to the input of the field effect transistor unit **22**. A small weight **28** is secured to the lower end of the antenna element **26** to hold it in the extended position. Similarly, the upper antenna element **24** extends in the other direction, and it may either form the support for the radiosonde unit **12** or may be closely associated with the supporting cable. A parachute **30** is provided for safe return of the instrument package to ground.

A ground or receiving station **32** may include an antenna **34**, receiver and demodulator **36**, and a recording apparatus **38**.

FIG. 2 shows a typical recording of the electrostatic field obtained as the ballon **14** and instrument package **12** rise through the successive layers of clouds **42**, **44**, and **46**, along the center line of the drawing. It is known that the electrostatic potential in the atmosphere increases from ground potential to plus 300,000 volts at elevations of about 30 miles. It is also known that the atmospheric electric field, which is the gradient of the potential, is substantially increased within clouds. As the package enters the lower edge of a cloud, the sudden increase in electric field causes a pulse of current to flow through resistor R_1 in one direction, and upon leaving the cloud, the sudden reduction in electric field causes an oppositely directed current pulse. This produces the positive swing shown at **48** in FIG. 2 as the unit enters the cloud and the negative peak **50** as the apparatus is rising through the upper surface of the cloud stratus **42**. A similar pattern is observed as the unit goes through the higher cloud formations **44** and **46**. With a knowledge of the speed of ascent of the balloon and instrument package, the location of the upper and lower surfaces of successive cloud layers may be determined by the present apparatus. Accordingly, despite the presence of a relatively low cloud layer which completely obscures other cloud formations, ground personnel may readily determine the meterological conditions relating to clouds above this low ceiling.

Returning to FIG. 1, the radiosonde equipment represented by blocks **16**, **18** and **20** is well known. The meterological radiosonde system which will be taken as typical is designated by the military by the numbers AN/AMT 4B. The Army technical manual which describes this radiosonde system is identified as TM 11–2432A–TO 31M4–2AMT–11, dated June 26, 1958. The radiosonde transmitter operates at a frequency of 1680 megacycles per second. This transmitter is modulated by a blocking oscillator **18**, the frequency of the blocking oscillator being controlled by the meteorological conditions which are detected. Normally, a thermistor for measuring the temperature and a humidity sensor are alternately switched to the input terminals of the blocking oscillator **18**. In the present case, the cloud detector circuitry is connected to both of these terminals. The barometric pressure sensor **20** may also be retained in the unit, and it may be connected to control the frequency of the blocking oscillator **18** by a switching action as described below.

With reference to FIG. 3, the humidity channel input terminals **62** and the temperature channel input terminals **64** of the standard radiosonde unit are shown at the right-hand side of the circuit. Atmospheric electric signals received by the dipole antenna elements **24** and **26** are applied to the field effect transistor **66** and are then coupled by a suitable circuit to the input terminals **62** and **64** of the radiosonde. While other field effect transistors may be employed, type C 610 of Crystallonics, Inc., was found to be suitable from a sensitivity and reliability standpoint for the present purposes. The input to the field effect transistor is shunted by a 1,000 megohm resistor R_1 to stabilize the input characteristic. Suitable biasing of the transistor **66** is provided by resistor R_3. Because the impedance of the transistor **66** is substantially lower than that of the temperature and humidity sensors which are normally employed, a 110,000 ohm resistor in the blocking oscillator was removed and a capacitor C was connected in parallel to the input terminals. The capacitor was selected to produce a modulation frequency of approximately 100 cycles per second in the absence of an input signal. Positive and negative voltages will then raise or lower this frequency.

In the radiosonde apparatus, signals from the pressure sensor **20** are normally employed to switch from the temperature channel terminals **64** to the humidity channel terminals **62**. This switch is well known in the art as a baroswitch. The barometric pressure switching action provides an indication of altitude, so it is useful to preserve this information. Accordingly, the resistor R_2 is employed between the transistor **66** and one terminal **64** to reduce the output signal slightly, thus changing the modulation level and preserving the pressure and thus altitude information.

With regard to the length of the dipole elements **24** and **26**, the size of resistor R_1 and the amplification of the field effect transistor, these are fixed by several factors. First, the antenna elements should be large enough to provide a substantial input signal, but should be relatively small as compared with normal cloud thicknesses. Lengths of 5 to 50 feet for each dipole would be of the proper order of magnitude. The resistor R_1 was chosen to reduce the input impedance between dipoles **24** and **26** below the point where fog and dampness and the resultant shunt impedance will introduce instability into the transmitted signals. With these parameters, and a speed of ascent of the order of 5 meters per second, it was determined that a single field effect transistor provided the necessary amplification for operation with the standard radiosonde unit.

As mentioned generally above, cloud radars are subject to failure under certain atmospheric conditions. Thus, the radar return is proportional to the sixth power of the droplet or particle size, while the human eye and optical systems respond to the second power of the droplet size. With the radar return proportional to such a high power of the droplet diameter, if a radar is adjusted to pick up a cloud having large particles, other clouds having small size particles are not detected. The present electrostatic system, however, responds in a manner which is nearly the same as the optical response, and therefore does not fail under atmospheric conditions where different size droplets or particles are present in successive clouds.

It is to be understood that the above described arrangements are illustrative of the application of the principles of the invention. Numerous other arrangements within the scope of the invention may be devised by those skilled in the art. Thus, by way of example and not of limitation, a somewhat different shape of antenna could be employed to pick up electrostatic field variations and apply them to the field effect transistor, an inherently stabilized transistor may be used, and the instrument package may be carried by rocket or other suitable propulsion arrangements than the balloon shown in the drawings. Accordingly, it is evident that various changes may be made in the present invention without departing from the spirit of the invention as defined in the present claims.

What is claimed is:

1. An apparatus for sensing electrostatic conditions in the atmosphere comprising:

a radiosonde apparatus including means for modulating the output frequency thereof, said means including an R-C circuit;

a pair of probes positioned in respectively different locations in the atmosphere with respect to said radiosonde;

a field effect transistor having its drain and gate terminals connected across said pair of probes and having its source and drain terminals connected in series with the resistance of said R-C circuit to modulate said radiosonde; and

a stabilizing high resistance connected across the two probes and across said gate and drain terminals of said transistor.

2. In an apparatus for sensing atmospheric electrostatic field conditions;

a balloon;

an instrument package connected to and spaced from said balloon, said instrument package including a transmitter, means including an R-C circuit for modulating said transmitter, and a field effect transistor having source and drain terminals connected in series with the resistance in said R-C circuit to modulate said transmitter;

antenna means including an antenna and resistance means connected across said antenna, said resistance means also being connected across the gate and the drain of said field effect transistor, said antenna extending upward from said package toward said balloon and downwardly from said package for applying signals to said field effect transistor in response to said field conditions to render said modulating means responsive to said field conditions.

3. An apparatus for sensing changes of the atmospheric electric field at cloud boundaries, which comprises:

a blocking oscillator-type modulated radiosonde including fixed resistance means and capacitance means connected in parallel with said fixed resistance means, said capacitance means being effective to discharge through said resistance means to control the modulation of said radiosonde;

dipole antenna means responsive to changes of the atmospheric electric field for producing a signal indicative of said changes;

resistance means connected across said dipole antenna means; and

a field effect transistor having source and drain terminals connected in series with said fixed resistance means and a gate terminal connected to said dipole antenna means for reception of said signal, said field effect transistor being responsive to said signal for varying the rate of discharge of said capacitance means to cause the blocking oscillator to modulate said radiosonde in accordance with the second changes in the atmospheric electric field.

4. An apparatus for sensing changes of the atmospheric electric field at cloud boundaries, which comprises:

radiosonde means including a blocking oscillator having fixed resistance means and capacitance means connected in parallel with said fixed resistance means, said capacitance means being effective to discharge through said resistance means to control the frequency of oscillation of said blocking oscillator;

dipole antenna means responsive to changes of the atmospheric electric field for producing a signal indicative of said changes;

resistance means connected across said dipole antenna; and

a field effect transistor having source and drain terminals connected in series with said fixed resistance means and a gate terminal connected to said dipole antenna means for reception of said signal, said field effect transistor being responsive to said signal for varying the rate of discharge of said capacitance means to control the frequency of oscillation of said blocking oscillator in accordance with the sensed changes in the atmospheric electric field.

(57) **ABSTRACT**

A mechanism to tap an electrical source which uses an aircraft (preferably a lighter than air balloon) tethered by a conductive line. The conductive line is extended/withdrawn by a winch motor to adjust the altitude of the aircraft. The conductive line is isolated from the ground and an electrical conductor is connected to the conductive line and to an electrical load. In this manner, static electricity generated in the atmosphere is gathered for use.

ATMOSPHERIC ELECTRICAL GENERATOR

BACKGROUND OF THE INVENTION

[0001] This invention relates to the production of electrical energy and more particularly to the production of electrical energy from the atmosphere.

[0002] Everyone is familiar with Benjamin Franklin's kite experiment of 1752. Using a kite whose string had become wet, negative charges from the passing clouds flowed into the string, down to the suspended key, and then into a Leyden jar via a thin metal wire. Franklin was protected by a dry silk string; but, when Franklin's knuckle came too close to the key, he received a strong shock. Fortunately, Benjamin Franklin was not killed, others who tried this same experiment were not so lucky.

[0003] Since then, the formation of lightning has remained something of a mystery. Lightning bolts are triggered when a negatively charged cloud base induces a positive charge from the ground, thereby forming a "pathway" for the discharge of the collected electrical energy.

[0004] Lightning travels up to 60,000 miles per hour with a flash that is brighter than ten million 100-watt lightbulbs. This wattage is as much power as is produced by all of the electricity plants in the United States and with a voltage of up to 300 million volts.

[0005] It is this very fact, the power within lightning is immense, that has prevented any successful collection of the electrical energy from lightning. The electricity in lightning is far too extreme for current technology to harness.

[0006] While lightning has attracted a energy starved industrial world, no one has developed any technique to harness this naturally occurring electrical source.

[0007] It is clear there is a continuing need for an electrical source other than carbon-based fuels and that the naturally occurring electricity in the atmosphere is being ignored.

SUMMARY OF THE INVENTION

[0008] The invention is a mechanism which taps into the naturally occurring static electricity in the atmosphere. Whereas heretofore, the attempt to garner electricity from the atmosphere has focused exclusively on capturing lightning, the present invention syphons off the static electricity which is generated from any agitated air and voids lightning.

[0009] Lightning is only the final discharge of the static electricity, whether that lightning is intra-cloud lightning, cloud-to-ground lightning, or inter-cloud lightning. Other types of final discharges are known as heat lightning, summer lightning, sheet lightning, ribbon lightning, silent lightning, ball lightning, bead lightning, elves, jets, and sprites. Well before these discharges are observed, as the atmosphere becomes agitated by wind or thermal, static electricity is being generated.

[0010] The present invention recognizes that this static electricity is being formed and creates a mechanism to capture it.

[0011] The mechanism of this invention utilizes an aircraft such as a lighter than air balloon. While the preferred embodiment uses a foil balloon, a variety of other aircraft are obvious to those of ordinary skill in the art, including, but not limited to: gliders, rubber balloons (such as weather balloons), biaxially-oriented polyethylene terephthalate polyester film balloons, and latex balloons.

[0012] Within this discussion, the balloon is referenced, but, the invention is not intended to be limited solely to balloons.

[0013] The balloon is sent aloft and is tethered by a conductive line. In this context, the conductive line may be any obvious to those of ordinary skill in the art. For the preferred embodiment, the conductive line is a generically referred to as a "poly-rope" and is commercially available through a variety of sources. A suitable conductive line is described in U.S. Pat. No. 5,203,542, entitled "Apparatus for Improved Electric Fence Wire Construction for use with Intensive Grazing" issued Apr. 20, 1993, to Coley, et al. and incorporated hereinto by reference.

[0014] The conductive line is played out of a winch to control the altitude of the balloon. The motor controlling the winch is able to reverse direction to both extend and withdraw the conductive line which is wrapped around a spool on the winch. The winch/spool combination are part of a base unit.

[0015] In some embodiments of the invention, the spool is constructed of rubber so as to insulate the conductive line from the winch assembly. In this embodiment, only the conductive line is charged by the atmospheric static electricity while the winch remains neutral.

[0016] In yet another embodiment, the winch/spool are part of a base unit which is itself isolated from the ground by an insulator. In this embodiment, the entire base unit is charged by the atmospheric static electricity.

[0017] A conductor, such as an insulated wire, is electrically connected to the conductive line. In one embodiment, where the conductive line is electrically isolated from the spool and winch motor, the conductor is connected to the conductive line. In the embodiment where the conductive line is electrically connected to the base unit, then the conductor is connected anywhere on a metallic base unit.

[0018] The other end of the conductor is connected to a load. The load in this case can be any of a variety of electrical loads well known to those of ordinary skill in art, including, but not limited to a motor, a battery system, or the electrical grid for the system.

[0019] In the preferred embodiment, a sensor array is used to monitor the activities both at the base unit (such as electrical flow within the conductor) and in the surrounding locale.

[0020] A sensor monitoring the electrical flow (i.e. voltage and/or current) within the conductor is used to monitor the electrical activity within the conductor.

[0021] In the preferred embodiment, a lightning sensor monitors for lightning activity within the locale. As noted earlier, the electrical characteristic of lightning is so extreme that ideally this discharge is avoided as it might damage the mechanism of this invention.

[0022] The sensor array is utilized by a controller, such as microprocessor, programmed to operate the mechanism as outlined herein.

[0023] The controller operates the winch motor to extend or withdraw the conductive line and by extension the altitude of the balloon. The controller is programmed to operate the winch by monitoring the electrical characteristics of the conductor and adjusting the balloon's altitude to maintain these characteristics within the conductor within a preset range.

[0024] This preset range is established either in the base programming of the controller or is established by an operator of the system.

[0025] As example, by controlling the amount of current being withdrawn from the atmosphere, the mechanism oper-

ates within a safe range and also provides a relatively stable current flow from which a variety of activities can take place (such as DC-AC conversion).

[0026] The controller also utilizes the lightning sensor to protect the mechanism from a lightning strike. Should lightning be detected within a pre-determined range (as established by the software or defined by an operator), then the balloon is pulled down to minimize the risk of damage from a lightning strike.

[0027] The invention, together with various embodiments thereof will be more fully explained by the following description of the accompanying drawings.

DRAWINGS IN BRIEF

[0028] FIG. **1** diagrams the preferred embodiment of the invention.

[0029] FIG. **2** illustrates the collection of the negative charged particles in the atmosphere.

[0030] FIG. **3** is a flow-chart of the operation of the controller for the preferred embodiment of the invention.

[0031] FIGS. **4**A, **4**B, and **4**C are electrical schematics for handling the static charge from the atmosphere.

[0032] FIG. **5** illustrates a conductive line used in the preferred embodiment of the invention.

[0033] FIGS. **6**A and **6**B illustrate an alternative conductive line creating an ionized pathway for the flow of the static charges from the atmosphere.

[0034] FIG. **7** illustrates the controller of an alternative embodiment and the associated safety devices.

[0035] FIGS. **8**A and **8**B illustrate two embodiments of enhanced electrical collection leads.

DRAWINGS IN DETAIL

[0036] FIG. **1** diagrams the preferred embodiment of the invention.

[0037] Balloon **10** is an aircraft which, in this illustration, is a lighter than air balloon. Wings **10**A, extending from the body of balloon **10**, provide additional lift in air flow **18**. Tail **10**B helps to stabilize balloon **10**.

[0038] Balloon **10** is tethered to the ground via conductive line **12**. As noted earlier, a variety of configurations and materials are available to serve as conductive line **12**. In this illustration, a poly-wire is used. Poly-wire is commercially available through a variety of vendors, including, but not limited to: Jeffers Livestock and Sareba Systems, Inc. of Ellendale, Minn.

[0039] In this embodiment, located proximate to balloon **10**, is an electrical collection enhancement lead **11** which assists in the collection of the static electrical charge in the atmosphere. Electrical collection enhancement lead **11** is configured to attract the static charge and conduct the charge into the conductive line **12**.

[0040] The electricity flows down the conductive line into spool **13**, where the conductive line **12** is collected and either withdrawn or dispensed through operation of winch motor **14**.

[0041] Winch motor **14** and spool **13** are mounted onto base unit **16** which is electrically isolated from ground **7** using insulator **17**. Note, in this embodiment of the invention, when electricity is being collected from the atmosphere, the entire base unit **16** becomes charged. In another embodiment of the invention, spool **13** is constructed of rubber, thereby preventing base unit **16** from becoming charged, thereby restricting the charging from the atmosphere to only conductive line **12**.

[0042] In this embodiment, conductor **6** is connected to base unit **16** (since the entire base unit **16** is charged and the base unit is metallic) to communicate the electrical current to load **5**. Conductor **6** is ideally an insulated wire.

[0043] The electrical current through conductor **6** is measured using sensor **8**.

[0044] In the alternative embodiment discussed above, where only the conductive line **12** is charged, then conductor **6** is connected to conductive line **12**.

[0045] Controller **15**, located in this embodiment on base unit **16**, operates winch motor **14** in response to signals from sensor **8** (measuring the current being discharged to load **5**) to maintain the current flow within a pre-defined range. As the current flow diminishes, then the conductive line **12** extended from spool **13** to increase the altitude of balloon **10** to that more static charge from the atmosphere is gathered; as the current flow falls exceeds a preset level, conductive line **12** is withdrawn onto spool **13** to decrease the static charge being collected from the atmosphere.

[0046] The range of current flow through conductor **6** is ideally set by the program, although some embodiments of the invention permit an operator to establish this range of operation.

[0047] In an alternative embodiment, the sensor monitoring conductor **6** monitors the voltage therein.

[0048] In the preferred embodiment of the invention, controller **15** is also equipped with a lightning sensor **19**. In this embodiment, when lightning is sensed within a preset range, then substantially all of conductive line **12** is wound onto spool **13** to pull balloon **10** near the ground and protect the entire mechanism from being damaged from a lightning discharge.

[0049] In the preferred embodiment, the "safe" distance form lightning is set in the programming of controller **15** and is ideally two miles; other embodiments permit the operator to "safe" distance.

[0050] There are a variety of lightning sensors well known to those of ordinary skill in the art, including, but not limited to those described in: U.S. Pat. No. 7,016,785, entitled "Lightning Detection" issued to Makela, et al. on Mach 21, 2006; U.S. Pat. No. 6,829,911, entitled "Lightning Detection and Prediction Alarm Device" issued to Jones, et al. on Dec. 7, 2004; U.S. Pat. No. 7,200,418, entitled "Detection of Lightning" issued to Karikuranta, et al. on Apr. 3, 2007; and U.S. Pat. No. 6,961,662, entitled "Systems and Methods for Spectral Corrected Lightning Detection" issued to Murphy on Nov. 1, 2005; all of which are incorporated hereinto by reference.

[0051] In another embodiment of the invention, controller **15** is not located on base unit **16**, rather it is remote and communicates its control signals to winch motor **14** using radio waves.

[0052] FIG. **2** illustrates the collection of the negative charged particles in the atmosphere.

[0053] Static charges **23** are generated in the atmosphere by agitated air. These static charges are often collected at the bottom of clouds, but exist in other environments as well.

[0054] Balloon **21** is extended into this strata of static charges **23** which are then attracted to conductive line **12** to flow to base unit **22** and then onto load **5**.

[0055] By increasing or decreasing the altitude of balloon **21** (defined by the length of the extended conductive line **12**),

conductive line **12** is selectively exposed to varying densities and levels of the static charge strata, and by extension, the current flow or voltage is increased or decreased.

[0056] FIG. **3** is a flow-chart of the operation of the controller for the preferred embodiment of the invention.

[0057] Once the program starts **30**, the lightning sensor is checked to determine if lightning has occurred within the unsafe range **31**A, if it has, then the balloon is lowered **32**A, and the program continues monitoring the status of lightning until no lightning is detected.

[0058] When the lightning status is acceptable, then the current within the conductor is checked to see if the current is within the prescribed range **31**B. If the current is acceptable (within range) the program returns to check the lightning status **31**A; otherwise a determination is made to see if the current is above the prescribed range **31**C.

[0059] If the current is above the prescribed range, then the altitude of the balloon is withdrawn a set amount **32**B (ideally twenty-five feet) and the program loops back to see if the current is within range **31**B.

[0060] If the current is below the prescribed range, then the altitude of the balloon is extended a set amount **32**C (ideally twenty-five feet) and the program loops back to see if the current is within range **31**B.

[0061] In this manner of feed-back and minor adjustments in the altitude of the balloon, the current is maintained within a prescribed range which can be handled by the downstream electrical system.

[0062] As noted earlier, some embodiments of the invention monitor the voltage instead of the current.

[0063] FIGS. **4**A, **4**B, and **4**C are electrical schematics for handling the static charge from the atmosphere.

[0064] By maintaining the voltage being collected in a prescribed range, an electrical conversion system is easily designed. While FIGS. **4**A, **4**B, and **4**C illustrate some electrical configurations, those of ordinary skill in the art readily recognize a variety of other configurations which will serve the same function.

[0065] Referencing FIG. **4**A, Direct Current In (DC IN) **40** is buffered by a gang of capacitors **41** before being communicated to a DC/AC converter **42**. The DC/AC converter converts the direct current into a an alternating current suitable for placement over an existing electrical grid **43** such as normally found from a power-plant.

[0066] Those of ordinary skill in the art readily recognize a variety of DC/AC converters, including, but not limited to: U.S. Pat. No. 7,394,671, entitled "Controller IC, DC-AC Conversion Apparatus, and parallel running system of DC-AC Conversion Apparatuses" issued to Fukumoto, et al. on Jul. 1, 2008; and, U.S. Pat. No. 7,330,366, entitled "DC-AC Converter" issued to Lee, et al. on Feb. 12, 2008; all of which are incorporated hereinto by reference.

[0067] FIG. **4**B illustrates an electrical arrangement suitable for use in charging a battery. DC IN **40** is buffered by capacitor bank **41** before entering into a step down transformer **43**. Step down transformer **43** reduces the voltage so that the voltage can safely be introduced into battery **44** which is connected to ground **45** at the battery's other pole.

[0068] Those of ordinary skill in the art readily recognize a variety of batteries which will work in this capacity, including, but not limited to those described in: U.S. Pat. No. 7,378,181, entitled "Electric Storage Battery Construction and Manufacture" issued to Skinlo on May 27, 2008; U.S. Pat. No. 7,388,350, entitled "Battery with Electronic Compartment" issued to Wright on Jun. 17, 2008; U.S. Pat. No. 7,397,220, entitled "Connection Member and Battery Pack" issued to Uchida, et al. on Jul. 8, 2008; and, U.S. Pat. No. 7,375,492, entitled "Inductively Charged Battery Pack" issued to Calhoon, et al. on May 20, 2008; all of which are incorporated hereinto by reference.

[0069] In FIG. **4**C, DC IN **40** is fed into an adjustable rheostat **46** which is controlled by the controller so that the DC OUT **47** falls within a specified range.

[0070] FIG. **5** illustrates a conductive line used in the preferred embodiment of the invention.

[0071] This type of conductive line is commonly called poly-wire and consists of multiple interwoven strands of plastic **50**A and **50**B woven into a cord or rope arrangement having intertwined therein exposed metal wires **51**A and **51**B. While this illustration shows two plastic strands and two metal wires, any number of possible combinations is possible.

[0072] The exposed metal wires **51**A and **51**B attract the atmospheric static charge and transmit the charge down to the base unit (not shown).

[0073] FIGS. **6**A and **6**B illustrate an alternative conductive line creating an ionized pathway for the flow of the static charges from the atmosphere.

[0074] This conductive line utilizes a tube **60** having an outer layer **62** of PET Film (Biaxially-oriented polyethylene terephtalate polyester film) which provides exceptionally high tensile strength and is chemically and dimensionally stable. The tube has an ideal diameter of between two and three inches.

[0075] An interior metal coating **61** provides an initial conduit for the flow of static charge. The static charge through the metal forces the tube to expand due to the repulsion experienced by like charges. Further, the flow of electricity causes the interior of the tube **60** to become ionized to provide an additional pathway for the atmospheric static charges to the base unit (not shown).

[0076] Because outer layer **62** provides a gas barrier, the resulting ionization is not dissipated by air currents, thereby providing a highly stable pathway.

[0077] FIG. **7** illustrates the controller of an alternative embodiment and the associated safety devices.

[0078] In this embodiment, controller box **70**, resting on insulating pad **72**, is in communication with the sensors as described above. Using the input from these sensors, when there is flow of electricity through the base unit, warning flashing light **71** is illuminated. To electrically neutralize the mechanism, switch **73** is activated to pass any existing current into the ground **74**.

[0079] FIGS. **8**A and **8**B illustrate two embodiments of enhanced electrical collection leads.

[0080] Referencing FIG. **8**A, enhanced electrical collection lead **82** is a wire mesh which is in electrical communication with conductive line **81** and balloon **80**. Because of the significant amount of metal exposed by enhanced electrical collection lead **82**, more static electricity from the atmosphere is drawn to the collection lead **82**, and then down conductive line **81** to the base unit (not shown).

[0081] Conductive lead **82** is positioned proximate to balloon **80**.

[0082] In FIG. **4**B, poly-wire **83** has enhanced electrical collection leads **84** wrapped therearound. Collection leads **84** have pointed ends **85**A and **85**B which have a propensity to attract more electricity than rounded ends do.

[0083] It is clear from the foregoing that the present invention captures an entirely new source of electrical energy.

What is claimed is:

1. A mechanism to tap an electrical source comprising:

a) a lighter than air balloon;

b) a base unit having a spool of conductive line on a winch motor, one end of said conductive material secured to said lighter than air balloon, said winch motor capable of selectively extending or withdrawing said conductive line from said spool, one end of said conductive line connected to said lighter than air balloon;

c) an insulator electrically isolating said conductive line from ground; and,

d) a conductor having a first end electrically connected to said conductive line and a second end electrically connected to a load.

2. The mechanism to tap an electrical source according to claim **1**, further including a controller, said controller selectively operating said winch motor based upon a voltage level in said conductor.

3. The mechanism to tap an electrical source according to claim **2**,

a) further including an electrical flow sensor monitoring electrical flow through said conductor and generating an electrical flow indicia indicative of said electrical flow in said conductor, said electrical flow indicia communicated to said controller; and,

b) wherein said controller operates said winch motor such that said electrical flow indicia remains within a selected operating range.

4. The mechanism to tap an electrical source according to claim **3**, wherein said selected operating range is established by an operator.

5. The mechanism to tap an electrical source according to claim **4**, further including a warning light activated when said electrical flow indicia is non-zero.

6. The mechanism to tap an electrical source according to claim **3**,

a) further including a lightning sensor generating a lightning presence indicia indicative of lightning within a prescribed range, said presence indicia being communicated to said controller; and,

b) wherein said controller, in response to said lightning presence indicia, operates said winch motor to withdraw substantially all of said conductive line onto said spool.

7. The mechanism to tap an electrical source according to claim **6**, wherein said prescribed range is established by an operator.

8. The mechanism to tap an electrical source according to claim **3**, further including an electrical collection enhancement lead in electrical contact with a first end said conductive material, said electrical collection enhancement lead configured to attract static electricity.

9. The mechanism to tap an electrical source according to claim **8**, wherein said electrical collection enhancement lead is positioned proximate to said lighter than air balloon.

10. The mechanism to tap an electrical source according to claim **9**, wherein said electrical collection enhancement lead includes at least two pointed electrical conductors.

11. The mechanism to tap an electrical source according to claim **1**, wherein said insulator electrically isolates said conductive line from said winch motor.

12. The mechanism to tap an electrical source according to claim **1**, wherein said insulator electrically isolates said base unit from ground.

13. A mechanism comprising:

a) an airborne aircraft tethered by a conductive line secured to a winch capable of extending or withdrawing said conductive line from a spool, thereby adjusting an altitude of the airborne aircraft;

b) an insulator electrically isolating said conductive line from ground; and,

c) a conductor having a first end electrically connected to said conductive line and a second end electrically connected to a load.

14. The mechanism according to claim **13**, further including a controller, said controller selectively operating said winch motor based upon a voltage level in said conductor.

15. The mechanism to tap an electrical source according to claim **14**,

a) further including a lightning sensor communicating with said controller; and,

b) wherein said controller, in response to selected signals from said lightning sensor withdraws substantially all of said conductive line.

16. A mechanism to tap an electrical source comprising:

a) a lighter than air balloon;

b) a base unit having a spool of conductive line on a winch motor, one end of said conductive material secured to said balloon, said winch motor capable of adjusting an altitude of said lighter than air balloon by selectively extending or withdrawing said conductive line from said spool;

c) an insulator electrically isolating said conductive line from ground; and,

d) a conductor having a first end electrically connected to said conductive line and a second end electrically connected to a load;

e) a sensor array having,

  1) an electrical flow sensor monitoring electrical flow through said conductor, and,

  2) a lightning sensor monitoring existence of proximate lightning; and,

f) a controller responsive to signals from said sensor array to selectively operate said winch motor.

17. The mechanism to tap an electrical source according to claim **16**,

a) further including a warning light; and,

b) wherein said controller activates said warning light when said electrical flow in said conductor is non-zero.

18. The mechanism to tap an electrical source according to claim **17**, further including an electrical collection enhancement lead in electrical contact with said conductive material, said electrical collection enhancement lead configured to attract static electricity and positioned proximate to said lighter than air balloon.

UNITED STATES PATENT OFFICE.

HERMANN PLAUSON, OF HAMBURG, GERMANY.

CONVERSION OF ATMOSPHERIC ELECTRIC ENERGY.

Application filed January 13, 1921. Serial No. 437,107.

To all whom it may concern:

Be it known that I, Hermann Plauson, Esthonian subject, residing in Hamburg, Germany, have invented certain new and useful Improvements in the Conversion of Atmospheric Electric Energy, of which the following is a specification.

Methods of obtaining atmospheric electricity by means of metallic nettings set with spikes which are held by means of ordinary or anchored kite balloons made of fabrics and filled with hydrogen, are in theory already known. Atmospheric electricity obtained in this way has been suggested to be used in the form of direct current for the charging of accumulators. This knowledge however is at present only theoretical as the conversion in practice has hitherto been a failure. No means are known of protecting the apparatus from destruction by lightning. The balloons used for collecting the charge must also be made of very large size in order to be able to support the weight of the metallic netting and the heavy cable connections.

Instead of using heavy metallic netting as collectors attached to single air balloons of non-conducting materials which are liable to be torn and are permeable to the gas, it is proposed to use metallic balloon collectors which have the following important advantages—

(*a*) The metallic cases are impenetrable to helium and hydrogen; they also represent large metallic weather-proof collecting surfaces.

(*b*) Radio active means and the like may be easily applied internally or externally; whereby the ionization is considerably increased and therewith also the quantity of atmospheric electricity capable of being collected.

(*c*) Such balloon collectors of light metal do not require to be of large size as they have to carry only their own moderate weight, and that of the conducting cable or wire.

(*d*) The entire system therefore offers little surface for the action of storm and wind and is resistant and stable.

(*e*) Each balloon can be easily raised and lowered by means of a winch so that all repairs, recharging and the like can be carried out without danger during the operation.

It is further proposed to use a collecting aerial network of several separate collectors spread out in the air above the earth, which collectors are interconnected by electrical conductors.

According to this invention charges of atmospheric electricity are not directly converted into mechanical energy, and this forms the main difference from previous inventions, but the static electricity which runs to earth through aerial conductors in the form of direct current of very high voltage and low current strength is converted into electro-dynamic energy in the form of high frequency vibrations. Many advantages are thereby obtained and all disadvantages avoided.

The very high voltage of static electricity of a low current strength can be converted by this invention to voltages more suitable for technical purposes and of greater current strength. By the use of closed oscillatory circuits it is possible to obtain electromagnetic waves of various amplitude and thereby to increase the degree of resonance of such current. Such resonance allows various values of inductance to be chosen whereby again the governing of the starting and stopping of machines driven thereby by simply tuning the resonance between coils of the machine and the transformer circuit forming the resonance can easily be obtained. Further, such currents have the property of being directly available for various uses, even without employing them for driving motors, of which there may be particularly mentioned, lighting, production of heat and use in electro-chemistry.

Further, with such currents a series of apparatus may be fed without direct current supply through conductors and also the electro-magnetic high frequency currents may be converted by means of special motors adapted for electro-magnetic oscillations into mechanical energy, or finally converted by special machines into alternating current of low frequency or even into direct current of high potential.

The invention is more particularly described with reference to the accompanying diagrams in which:—

Figure 1 is an explanatory figure.

Figure 2 is a diagrammatic view of the simplest form.

Figure 3 shows a method of converting atmospheric electrical energy for use with motors.

Figure 36 shows an incandescent collector with Nernst lamp.

Figure 37 shows a form with a gas flame.

Figure 1 illustrates a simple diagram for converting static electricity into dynamic energy of a high number of oscillations. For the sake of clearness in the drawings an influence machine is assumed to be employed and not an aerial antenna. 13 and 14 are combs for collecting the static electricity of the influence machine. 7 and 8 are spark discharging electrodes, 6 and 5 condensers, 9 an inductive primary coil, 10 secondary coil, 11 and 12 ends of conductors of the secondary coil 10. When the disc of the static influence machine is rotated by mechanical means, the combs collect the electric charges one the positive and the other the negative, and charge the condensers 5 and 6 until such a high potential is formed across the spark gap 7—8, that the spark gap is jumped. As the spark gap 7—8 forms a closed circuit with condensers 6 and 5, and inductive resistance 9, as is well known, waves of high frequency electromagnetic oscillations will pass in this circuit.

The high frequency of the oscillations produced in the primary circuit induces waves of the same periodicity in the secondary circuit. Thus in the primary circuit electromagnetic oscillations are formed by the passage of the spark over the spark gap and these waves are maintained by fresh charges of static electricity.

By suitably selecting the ratio between the number of the coils in the primary and secondary circuits with regard to a correct application of the co-efficients of resonance (capacity, inductance, and resistance) the high voltage of the primary circuit may be suitably converted into low voltage and high current strength.

When the oscillatory discharges in the primary circuit becomes weaker or entirely cease, the condensers are charged again by the static electricity until the accumulated charge again breaks down the spark gap. All this is repeated as long as electricity is produced by the static machine by employing mechanical energy.

An elementary form of the invention is shown in Figure 2 in which two spark gaps in parallel are used one of which may be termed the working gap 7 in Figure 2, whilst the second serves as a safety device for excess voltage and consists of a larger number of spark gaps than the working section, which gaps are arranged in series and are bridged by very small capacities as is illustrated in a_1, b_1, c_1, Figure 2 which allow of uniform sparking in the safety section.

In Figure 2 A is the aerial antenna for collecting charges of atmospheric electricity, 13 is the earth connection of the second part of the spark gap, 5 and 6 are condensers, 9 a primary coil. Now when through the aerial A the positive atmospheric electricity seeks to combine with the negative charge to earth, this is prevented by (the air gap between) the spark gaps. The resistance of the spark gap 7 is, as shown in the drawings, lower than that of the other safety section which consists of three spark gaps connected in

series, and consequently a three times greater air resistance is offered by the latter.

So long therefore, as the resistance of the spark gap 7 is not overloaded, so that the other spark gaps have an equal resistance with it the discharges take place only over spark gap 7. Should however the voltage be increased by any influences so that it might be dangerous for charging the condensers 5 and 6 or for the coil insulation 9 and 10 in consequence of break down, by a correct regulation of this spark gap the second spark gap can discharge free from inductive effects direct to earth without endangering the machine.

Without this second spark gap, arranged in parallel having a higher resistance than the working spark gap it is impossible to collect and render available large quantities of electrical energy.

The action of this closed oscillation circuit consisting of spark gap 7, two condensers 5 and 6, primary coil 9, and also secondary coil 10 is exactly the same as the one described in Figure 1 with the arrangement of the static induction machine with the only difference that here the second spark gap is provided. The electromagnetic high frequency alternating current obtained can be tapped off from the conductors 11 and 12 for lighting and heating purposes. Special kinds of motors adapted for working with these peculiar electrical charges may be connected at 14 and 15 which can work with static electricity charges or with high frequency oscillations.

In addition to the use of spark gaps in parallel a second measure of security is also necessary for taking off the current. This precaution consists according to this invention, in the introduction of and method of connecting certain protective electromagnets or choking coils in the aerial circuit as shown by S in Figure 3.

A single electromagnet only having a core of the thinnest possible separate laminations is connected with the aerial.

In the case of high voltages in the aerial network or at places where there are frequent thunder storms, several such magnets may however be connected in series.

In the case of large units or plants several electromagnets can be employed in parallel or in series parallel.

The windings of these electromagnets may be simply connected in series with the aerials. In this case the winding preferably consists of several thin parallel wires, which make up together, the necessary section.

The winding may be made of primary and secondary windings in the form of a transformer. The primary winding will be then connected in series with the aerial network, and the secondary winding more or less short-circuited over a regulating resistance or an induction coil. In the latter case it is possible to regulate to a certain extent the effect of the choking coils. In the further description of the connecting and constructional diagrams the aerial electromagnet choke coil is indicated by a simple ring S.

Figure 3 shows the simplest way of converting atmospheric electricity into electromagnetic wave energy by the use of special motors adapted for high oscillatory currents or static charges of electrical energy. Recent improvements in motors for working with static charges and motors working by resonance, that is to say, having groups of tuned electromagnetic cooperating circuits render this possible but such do not form part of the present invention.

A motor adapted to operate with static charges will for the sake of simplicity be diagrammatically indicated by two semicircles 1 and 2 and the rotor of the motor by a ring M. (Figure 3.) A is a vertical aerial or aerial network. S the safety choke or electromagnet with coil O as may be seen is connected with the aerial A. Adjacent the electromagnet S the aerial conductor is divided into three circuits, the circuit 8 giving the safety spark gap, the circuit 7 with the working spark gap, and then a circuit including the stator terminal 1, the rotor and stator terminal 2 at which a connection is made to the earth wire. The two spark gaps are also connected metallically with the earth wire. The method of working these diagrams is as follows:

The positive atmospheric electric charge collected tends to combine with the negative electricity (or earth electricity) connected with the earth wire. It travels along the aerial A through the electromagnet S without being checked as it flows in the same direction as the direct current. Further, its progress is arrested by two sparks gaps placed in the way and the stator condenser surfaces. The stator condenser surfaces are charged until the charge is greater than the resistance of the spark gap 7, whereupon a spark springs over the spark gap 7 and an oscillatory charge is obtained as by means of the motor M, stator surfaces 1 and 2, and spark gap 7, a closed oscillation circuit is obtained for producing the electromagnetic oscillations. The motor here forms the capacity and the necessary inductance and resistance, which, as is well known, are necessary for converting static electricity into electromagnetic wave energy.

The discharges formed are converted into mechanical energy in special motors and can not reach the aerial network by reason of the electromagnet or choke. If, however, when a spark springs over the spark gap 7 a greater quantity of atmospheric electricity tends to flow to earth, a counter voltage is

induced in the electromagnet, which is greater the more rapidly and strongly the flow of current direct to the earth is. By the formation of this opposing voltage a sufficiently high resistance is offered to the flow of atmospheric electricity direct to earth to prevent a short circuit with the earth.

The circuit containing spark gap 8 having a different wave length which is not in resonance with the natural frequency of the motor, does not endanger the motor and serves as security against excess voltage, which, as practical experiments have shown, may still arise in certain cases, but can be conducted direct to earth through this spark gap.

In the diagram illustrated in Figure 4 the spark gap 7 is shunted across condensers 5 and 6 from the motor M. This construction affords mainly a better insulation of the motor against excess voltage and a uniform excitation through the spark gap 7.

In Figure 5 a diagram is illustrated for transforming large current strengths which may be employed direct without motors, for example, for lighting or heating purposes. The main difference is that here the spark gap consists of a star shaped disc 7 which can rotate on its own axis and is rotated by a motor opposite similarly fitted electrodes 7^a. When separate points of stars face one another, discharges take place, thus forming an oscillation circuit over condensers 5 and 6 and inductance 9 for oscillatory discharges. It is evident that a motor may also be directly connected to the ends of the spiral 9.

The construction of the diagram shown in Figure 6 permits of the oscillation circuit of the motor being connected with an induction coil. Here a regulating inductive resistance is introduced for counter-acting excess voltages in the motor. By cutting the separate coils 9 (coupled inductively to the aerial) in or out the inductive action on the motor may be more or less increased or variable aerial action may be exerted on the oscillation circuit.

In Figure 7 the oscillation circuit is closed through the earth (E and E_1). The spark gap 7 may be prolonged or shortened by more or fewer spark gaps being successively connected by means of a contact arm 7^b.

Diagram 8 shows a unipolar connection of the motor with the aerial network. Here two oscillation circuits are closed through the same motor. The first oscillation circuit passes from aerial A through electromagnet S, point x, inductance 9^a to the earth condenser 6 and further, over spark gap 7 to the aerial condenser 5 and back to x. The second oscillation circuit starts from the aerial condenser 5 at the point x^1 over the inductance 9 to the earth condenser 6 at the point x^3 and through the condenser 6 over the spark gap 7 back to x^1. The motor itself is inserted between the two points of the spark gap 7. From this arrangement slightly damped oscillation wave currents are produced.

In the diagram illustrated in Figure 9 a loosely coupled system of connections is illustrated which is assumed to be for small motors for measuring purposes. A indicates the aerial conductor, S the electromagnet in the aerial conductor, 9 the inductance, 7 the spark gap, 5 and 6 condensers, E the earth, M the motor, and 1 and 2 stator connections of the motor. The motor is directly metallically connected with the oscillation circuit.

In Figure 10 a purely inductive coupling is employed for the motor circuit. The motor is connected with the secondary wire 10 as may be seen in Figure 11 in a somewhat modified diagram connection. The same applies to the diagram of Figure 12.

The diagrams hitherto described preferably allow of motors of small and medium strength to be operated. For large aggregates, however, they are too inconvenient as the construction of two or more oscillation circuits for large amounts of energy is difficult; the governing is still more difficult and the danger in switching on or off is greater.

A means of overcoming such difficulties is shown in Figure 13. The oscillation circuit here runs starting from the point x over condenser 5, variable inductance 9, spark gap 7 and the two segments (3^a and 4^a) forming arms of a Wheatstone bridge, back to x. If the motor is connected by brushes 3 and 4 transversely to the two arms of the bridge as shown in the drawings, electromagnetic oscillations of equal sign are induced in the stator surfaces 1 and 2 and the motor does not revolve. If however, the brushes 3 and 4 are moved in common with the conducting wires 1 and 2 which connect the brushes with the stator poles a certain alteration or displacement of the polarity is obtained and the motor commences to revolve.

The maximum action will result if one brush 3 comes on the central sparking contact 7 and the other brush 4 on the part x. They are however, usually in practice not brought on to the central contact 7 but only held in the path of the bridge segments 4^a and 3^a in order not to connect the spark gaps with the motor oscillation circuit.

As however, the entire oscillation energy can thereby not act on the motor it is better to carry out the same system according to the diagram 14. The diagram 14 differs from the foregoing only by the motor not being directly metallically connected with the segments of the commutator, but only a primary coil 9 which induces in a secondary coil 10, current which feeds the motor M and takes the place of the rotor. By this

arrangement a good transforming action is obtained, a loose coupling and also an oscillation circuit without a spark gap.

In Figure 15 the motor is not purely inductively as in 14, but directly metallically branched off from the primary coil (at x and x^1) after the principle of the auto-transformer.

In Figure 16 instead of an inductance a condenser 6 is in similar manner, and for the same object inserted between the segments 3^a and 4^a. This has the advantage that the segments 3^a and 4^a need not be made of solid metal but may consist of spiral coils whereby a more exact regulation is possible and further motors of high inductance may be employed.

The arrangements of Figures 17, 18 and 19 may be employed for use with resonance and particularly with induction condenser motors; between the large stator induction condenser surfaces, small reversing pole condensers are connected, which, as may be seen from Figures 17, 18 and 19 are led together to earth. Such reversing poles have the advantage that with large quantities of electrical energy the spark formation between the separate oscillation circuits ceases.

Figure 19 shows a further method which prevents electromagnetic oscillations of high number of alternations formed in the oscillation circuit striking back to the aerial conductor. It is based on the well known principle that a mercury lamp, one electrode of which is formed of mercury, the other of solid metal such as steel allows an electric charge to pass in only one direction from the mercury to the steel and not vice versa. The mercury electrode of the vacuum tube N is therefore connected with the aerial conductor and the steel electrode with the oscillation circuit. From this it results that charges can pass only from the aerial through the vacuum tube to the oscillation circuit, but not vice versa. Oscillations which are formed on being transformed in the oscillation circuit cannot pass to the aerial conductor.

In practice these vacuum tubes must be connected behind an electromagnet as the latter alone affords no protection against the danger of lightning.

As regards the use of spark gaps, all arrangements as used for wireless telegraphy may be used. Of course the spark gaps in large machines must have a sufficiently large surface. In very large stations they are cooled in liquid carbonic acid or better still in liquid nitrogen or hydrogen; in most cases the cooling may also take place by means of liquefied low homologues of the metal series or by means of hydrocarbons the freezing point of which lies at between —90° C. and —40° C. The spark gap casing must also be insulated and be of sufficient strength to be able to resist any pressure which may arise. Any undesirable excess super-pressure which may be formed must be automatically let off. I have employed with very good results mercury electrodes which were frozen in liquid carbonic acid, the cooling being maintained during the operation from the outside through the walls.

Figure 20 is one of the simplest forms of construction of an aerial network in combination with collectors, transformers and the like illustrated diagrammatically. E is here the earth wire, 8 the safety spark gap, 7 the working spark gap, 1 and 2 the stator surfaces of the motor, 5 a condenser battery, S the protective magnet which is connected with the coil in the aerial conductor, A^1 to A^{10} aerial antennæ with collecting balloons, N horizontal collecting or connecting wires from which, to the centre a number of connections run.

The actual collectors consist of metal sheaths preferably made of an aluminium magnesium alloy, and are filled with hydrogen or helium and are attached to copper plated steel wires. The size of the balloon is selected so that the actual weight of the balloon and the weight of the conducting wire is supported thereby. On the top of the balloon aluminium spikes, made and gilded in a special manner hereinafter described, are arranged in order to produce a conductor action. Small quantities of radium preparations, more particularly polonium-ionium or mesothorium preparations considerably increase the ionization, and therewith the action of these collectors.

In addition to metal balloons, fabric balloons which are superficially metal coated according to Schoop's metal spraying process, may however also be employed. A metallic surface may also be produced by lacquering with metallic bronzes, preferably according to Schoop's spraying process or lacquering with metallic bronze powders in two electrical series of widely different metals, because thereby the collecting effect is considerably increased.

Instead of the ordinary round balloons, elongated cigar shaped ones may be employed. In order also to utilize the frictional energy of the wind, patches or strips of non-conducting substances which produce electricity by friction, may be attached to the metallized balloon surfaces. The wind will impart a portion of its energy in the form of frictional electricity, to the balloon casing, and thereby the collecting effect is substantially increased.

In practice however, very high towers (up to 300 metres is fully admissible) may be employed as antennæ. In these towers copper tubes rise freely further above the top of the tower. A gas lamp secured

against the wind is then lit at the point of the copper tube and a netting is secured to the copper tube over the flame of this lamp to form a collector. The gas is conveyed through the interior of the tube up to the summit. The copper tube must be absolutely protected from moisture at the place at which it enters the tower and also rain must be prevented running down the walls of the tower which might lead to a bad catastrophe. This is done by bell shaped enlargements which expand downwards, being arranged in the tower in the form of high voltage insulators of Siamese pagodas.

Special attention must be devoted to the foundations of such towers. They must be well insulated from the ground, which may be obtained by first embedding a layer of concrete in a box form to a sufficient depth in the ground and inserting in this an asphalt lining and then glass bricks cast about 1 or 2 metres in thickness. Over this in turn there is a ferro-concrete layer in which alone the metal foot of the tube is secured. This concrete block must be at least 2 metres from the ground and be fully protected at the sides by a wooden covering, from moisture. In the lower part of the tower a wood or glass house for the large condenser batteries or for the motors may be constructed. In order to lead the earth connection to the ground water, a well insulated pit constructed of vitreous bricks, must be provided. Several such towers are erected at equal distances apart and connected with a horizontal conductor. The horizontal connecting wires may either run directly from tower to tower or be carried on bell shaped insulators similar to those in use for high voltage conductors. The width of the network may be of any suitable size and the connection of the motors can take place at any suitable places.

In order to collect large quantities of electricity with few aerials it is well to provide the aerial conductor with batteries of condensers as shown in two methods of construction in Figures 21 and 22. In Figure 21 the batteries of condensers 5 are connected on the one hand with the aerial electricity collectors Z by the aerial conductor A, and on the other hand interconnected in series with an annular conductor from which horizontal conductors run to the connecting points C to which the earth wire is connected.

Figure 22 shows a similar arrangement. Should two such series of antennæ rings be shown by a voltmeter to have a large difference of potential (for example, one in the mountains and one in the plain) or even of different polarity these differences may be compensated for by connecting sufficiently large condenser batteries (5, 5^a, 5^b) by means of Maji star conductors D and D^1. In Figure 23 a connection of three such rings of collectors to form a triangle with a central condenser battery is illustrated.

The condenser batteries of such large installations must be embedded in liquefied gases or in liquids freezing at very low temperatures. In such cases a portion of the atmospheric energy must be employed for liquefying these gases. It is also preferable to employ pressure. By this means the condenser surfaces may be diminished, and still allow for large quantities of energy to be stored, secure against breakdown. For smaller installations the immersing of the condensers in well insulated oil or the like, suffices. Solid substances on the other hand cannot be employed as insulators.

The arrangement in the diagrams hitherto described was always such that the condenser batteries were connected with both poles directly to the aerial conductors. An improved diagram of the connections for obtaining atmospheric electricity for the condenser batteries has however, been found to be very advantageous, this arrangement consists in that they are connected by only one pole (unipolar) to the collecting network. Such a method of arrangement is very important, as by means of it a constant current and an increase of the normal working pressure or voltage is obtained. If for example a collecting balloon aerial which is allowed to rise to a height of 300 metres, shows 40,000 volts above earth voltage, in practice it has been found that the working voltage (with a withdrawal of the power according to the method hereinbefore described by means of oscillating spark gaps and the like) is only about 400 volts. If however, the capacity of the condenser surfaces be increased, which capacity in the above mentioned case was equal to that of the collecting surface of the balloon aerials, to double the amount, by connecting the condenser batteries with only one pole, the voltage rises under an equal withdrawal of current up to and beyond 500 volts. This can only be ascribed to the favourable action of the connecting method.

In addition to this substantial improvement it has also been found preferable to insert double inductances with electromagnets and to place the capacities preferably between two such electromagnets. It has also been found that the useful action of such condensers can be further increased if an induction coil be connected as inductive resistance to the unconnected pole of the condenser, or still better if the condenser itself be made as an induction condenser. Such a condenser may be compared with a spring which when compressed carries in itself accumulated force, which it again gives off when released. In charging, a charge with reversed sign is formed at the

other free condenser pole, and if through the spark gap a short circuit results, the accumulated energy is again given back since now new quantities of energy are induced at the condenser pole connected with the conductor network, which in fact charges with opposite signs to that at the free condenser pole. The new induced charges have of course the same sign as the collector network. The whole voltage energy in the aerial is thereby however increased. In the same space of time larger quantities of energy are accumulated than is the case without such inserted condenser batteries.

In Figures 24 and 25 two different diagrams of connections are more exactly illustrated, Figure 24 shows a collecting balloon and the diagram of the connections to earth. Figure 25 four collecting balloons and the parallel connection of the condenser batteries belonging thereto.

A is the collecting balloon made of an aluminium magnesium alloy (electron metal, magnalium) of a specific gravity of 1.8 and a thickness of plate 0.1 to 0.2 mm. Inside there are eight strong vertical ribs of T shaped section about 10 to 20 mm. in height and about 3 mm. in thickness with the projecting part directed inwards (indicated by *a*, *b*, *c*, *d* and so forth); they are riveted together to form a firm skeleton and are stiffened in a horizontal direction by two cross ribs. The ribs are further connected with one another internally and transversely by means of thin steel wires, whereby the balloon obtains great power of resistance and elasticity. Rolled plates of 0.1 to 0.2 mm. in thickness made of magnalium alloy are then either soldered or riveted on this skeleton so that a fully metallic casing with smooth external surface is obtained. Well silvered or coppered aluminium plated steel wires run from each rib to the fastening ring 2. Further, the coppered steel hawser L preferably twisted out of separate thin wires (shown in dotted lines in Figure 24) and which must be long enough to allow the balloon to rise in the desired height, leads to a metal roller or pulley 3 and from thence to a winch W, well insulated from the earth. By means of this winch, the balloon, which is filled with hydrogen, or helium, can be allowed to rise to a suitable height (300 to 5,000 metres) and brought to the ground for recharging or repairs.

The actual current is taken directly through a friction contact from the metal roller 3 or from the wire, or even from the winch or simultaneously from all three by means of brushes (3, 3^a and 3^b). Beyond the brushes the conductor is divided, the paths being:—firstly over 12 to the safety spark gap 8, from thence to the earth conductor E^1, and secondly over electromagnet S^1, point 13, to a second loose electromagnet having an adjustable coil S^2, then to the spark gap 7 and to the second earth conductor E^2. The actual working circuit is formed through the spark gap 7, condensers 5 and 6, and through the primary coil 9; here the static electricity formed by oscillatory discharges is accumulated and converted into high frequency electromagnetic oscillations. Between the electromagnets S^1 and S^2 at the crossing point 13, four condenser batteries are introduced which are only indicated diagrammatically in the drawings each by one condenser. Two of these batteries (16 and 18) are made as plate condensers and prolonged by regulating induction coils or spirals 17 and 19 while the two others (21 and 23) are induction condensers. As may be seen from the drawings each of the four condenser batteries 16, 18, 21, 23 is connected only by one pole to the aerial or to the collector conductor. The second poles 17, 19, 22, 24 are open. In the case of plate condensers having no inductive resistance an induction coil is inserted. The object of such a spiral or coil is the displacement of phase of the induction current by ¼ periods, whilst the charging current of the condenser poles which lie free in the air, works back to the collector aerial. The consequence of this is that in discharges in the collector aerial the back inductive action of the free poles allows a higher voltage to be maintained in the aerial collecting conductor than would otherwise be the case. It has also been found that such a back action has an extremely favourable effect on the wear of the contacts. Of course the inductive effect may be regulated at will within the limits of the size of the induction coil, the length of the coil in action being adjustable by means of wire connection without induction (see Fig. 24, No. 20).

S^1 and S^2 may also be provided with such regulating devices in the case of S^2 (illustrated by 11). If excess voltage be formed it is conducted to earth through the wire 12 and spark gap 8 or through any other suitable apparatus, since this formation would be dangerous for the other apparatus.

The action of these condenser batteries has already been hereinbefore described.

The small circles on the collector balloon indicate places at which zinc amalgam or gold amalgam or other photoelectric acting metals in the form of small patches in extremely thin layers (.01 to .05 mm. in thickness) are applied to the balloon casing of light metal. Such metallic patches may also be applied to the entire balloon as well as in greater thickness to the conducting network. The capacity of the collector is thereby considerably strengthened at the surface. The greatest possible effect in collecting may be obtained by polonium amalgams and the like. On the surface of the

collector balloon metal points or spikes are also fixed along the ribs, which spikes serve particularly for collecting the collector charge. Since it is well known that the resistance of the spikes is less the sharper the spike is, for this purpose it is therefore extremely important to employ as sharp spikes as possible. Experiments made as regards these have shown that the formation of the body of the spike or point also plays a large part, for example, spikes made of bars or rollers with smooth surfaces, have a many times greater point resistance as collector accumulator spikes than those with rough surfaces. Various kinds of spike bodies have been experimented with for the collector balloons hereinbefore mentioned. The best results were given by spikes which were made in the following way. Fine points made of steel, copper, nickel, or copper and nickel alloys, were fastened together in bundles and then placed as anode with the points in a suitable electrolyte (preferably in hydrochloric acid or muriate of iron solutions) and so treated with weak current at 2 to 3 volts pressure. After 2 to 3 hours according to the thickness of the spikes or pins the points become extremely sharp and the bodies of the spikes have a rough surface. The bundle can then be removed and the acid washed off with water. The spikes are then placed as cathode in a bath consisting of solution of gold, platinum, iridium, paladium or wolfram salts or their compounds and coated at the cathode galvanically with a thin layer of precious metal, which must however be sufficiently firm to protect them from atmospheric oxidation.

Such spikes act at a 20 fold lower voltage almost as well as the best and finest points made by mechanical means. Still better results are obtained if polonium or radium salts are added to the galvanic bath when forming the protective layer or coating. Such pins have a low resistance at their points and even at one volt and still lower pressures have an excellent collector action.

In Figure 24 the three unconnected poles are not connected with one another in parallel. That is quite possible in practice without altering the principle of the free pole. It is also preferable to interconnect in parallel to a common collector network, a series of collecting aerials.

Figure 25 shows a diagram for such an installation. A^1, A^2, A^3, A^4 are four metal collector balloons with gold or platinum coated spikes which are electrolytically made in the presence of polonium emanations or radium salts, which spikes or needles are connected over four electro-magnets S^1, S^2, S^3, S^4, through an annular conductor R. From this annular conductor four wires run over four further electromagnets S^a, S^b, S^c, S^d, to the connecting point 13. There the conductor is divided, one branch passing over 12 and the safety spark gap 8 to the earth at E^1, the other over inductive resistance J and working spark gap 7 to the earth at E^2. The working circuit, consisting of the condenser 5 and 6 and a resonance motor or a condenser motor M, such as hereinbefore described, is connected in proximity round the sparking gap section 7.

Instead of directly connecting the condenser motor of course the primary circuit for high frequency oscillatory current may also be inserted.

The condenser batteries are connected by one pole to the annular conductor R and can be either inductionless (16 and 18) or made as induction condensers as shown by 21 and 23. The free poles of the inductionless condensers are indicated by 17 and 19, those of the induction condensers by 22 and 24. As may be seen from the drawings all these poles 17, 22, 19, 24 may be interconnected in parallel through a second annular conductor without any fear that thereby the principle of the free pole connection will be injured. In addition to the advantages already set forth the parallel connection also allows of an equalization of the working pressure in the entire collector network. Suitably constructed and calculated induction coils 25 and 26 may also be inserted in the annular conductor of the free poles, by means of which a circuit may be formed in the secondary coils 27 and 28 which allows current produced in this annular conductor by fluctuations of the charges or the like appearances to be measured or otherwise utilized.

According to what has been hereinbefore stated separate collector balloons may be connected at equidistant stations distributed over the entire country, either connected directly with one another metallically or by means of intermediate suitably connected condenser batteries through high voltage conductors insulated from earth. The static electricity is converted through a spark gap into dynamic energy of a high number of oscillations and may in such form be coupled as a source of energy by means of a suitable method of connecting, various precautions being observed and with special regulations. The wires leading from the collector balloons have hitherto been connected through an annular conductor without this endless connection, which can be regarded as an endless induction coil, being able to exert any action on the whole conductor system.

It has now been found that if the network conductor connecting the aerial collector balloons with one another is not made as a simple annular conductor, but preferably short circuited in the form of coils over a

condenser battery or spark gap or through thermionic tubes or valves or audions, then the total collecting network exhibits quite new properties. The collection of atmospheric electricity is thereby not only increased but an alternating field may be easily produced in the collector network. Further, the atmospheric electrical forces showing themselves in the higher regions may also be directly obtained by induction. In Figures 26 and 28 a form of construction is shown on the basis of which the further foundations of the method will be more particularly explained.

In Figure 26 1, 2, 3, 4 are metal collector balloons, 5, 6, 7, 8 their metallic aerial conductors and I the actual collector network. This consists of five coils and is mounted on high voltage insulators in the air, on high voltage masts (or with a suitable construction of cable embedded in the earth). One coil has a diameter of 1 to 100 km. or more. S and S¹ are two protective electromagnets, F the second safety section against excess voltage, E its earth conductor and E¹ the earth conductor of the working section. When an absorption of static atmospheric electricity is effected through the four balloon collectors, the current in order to reach the earth connection E¹ must flow spirally through the collector network over the electromagnet S, primary induction coil 9, conductor 14, anode A of the audion tube, incandescent cathode K, as the way over the electromagnet and safety spark gap F offers considerably greater resistance. Owing to the fact that the accumulated current flows in one direction, an electromagnetic alternating field is produced in the interior of the collector network coil, whereby the whole free electrons are directed more or less into the interior of the coil. An increased ionization of the atmosphere is therefore produced. In consequence of this the points mounted on the collector balloon show a considerably reduced resistance and therefore increased static charges between the points on the balloon and the surrounding atmosphere are produced. The result of this is a considerably increased collector effect.

A second effect which could not be obtained otherwise is obtained by the electromagnetic alternating field which running parallel to the earth surface, acts more or less with a diminishing or increasing effect on the earth magnetic field, whereby in the case of fluctuations in the current a return induction current of reversed sign is always produced in the collector coil by earth magnetism. Now if, however, a constantly pulsating continuous alternating field is produced as stated in the above collector network I, an alternating current of the same periodicity is produced also in the collecting network coil. As the same alternating field is further transmitted to the aerial balloon, the resistance of its points is thereby considerably reduced, whilst the collector action is considerably increased. A further advantage is that positive electrons which collect on the metal surfaces during the conversion into dynamic current produce a so-called drop of potential of the collector area. As an alternating field is present, the negative ions surrounding the collector surfaces, when discharge of the collector surfaces takes place produce by the law of induction, an induction of reversed sign on the collector surface and so forth (that is to say again a positive charge). In addition to the advantages hereinbefore set forth, the construction of connecting conductors in coil form when of sufficiently large diameter, allows of a utilization of energy arising in higher regions also in the simplest way. As is well known electric discharges frequently take place at very great elevations which may be observed, such as St. Elmo's fires or northern lights. These energy quantities have not been able to be utilized up to now. By this invention all these kinds of energy, as they are of an electromagnetic nature and the direction of the axis of the collector coils stands at right angles to the earth's surface, can be more or less absorbed in the same way as a receiver in wireless telegraphy absorbs waves coming from a far distance. With a large diameter of the spiral it is possible to connect large surfaces and thereby to take up also large quantities of energy.

It is well known that large wireless stations in the summer months, and also in the tropics are very frequently unable to receive the signals in consequence of interruptions which are caused by atmospheric electricity, and this takes place with vertical coils of only 40 to 100 m. diameter. If on the contrary horizontal coils of 1 to 100 km. diameter be employed very strong currents may be obtained through discharges which are constantly taking place in the atmosphere. Particularly in the tropics or still better in the polar regions where the northern lights are constantly present, large quantities of energy may probably be obtained in this way. A coil with several windings should act the best. In similar manner any alteration of the earth magnetism should act inductively on such a coil.

It is not at all unlikely that earthquakes and spots on the sun will also produce an induction in such collector coils of sufficient size. In similar manner this collector conductor will react on earth currents more particularly when they are near the surface of the earth or even embedded in the earth. By combining the previous kind of current collectors so far as they are adapted for

the improved system with the improved possibilities of obtaining current the quantities of free natural energy which are to be obtained in the form of electricity are considerably increased.

In order to produce in the improved collector coil uniform current oscillations of an undamped nature so-called audion high vacuum or thermionic tubes of suitable connection are employed instead of the previously known spark gaps (Fig. 26, Nos. 9–18). The main aerial current flows through electromagnet S (which in the case of a high number of alternations is not connected here but in the earth conductor E^1) and may be conveyed over the primary coils in the induction winding through wire 14 to the anode A of the high vacuum grid tube. Parallel with the induction resistance 9 a regulating capacity of suitable size, such as condenser 11 is inserted. In the lower part of the vacuum grid tube is arranged the incandescent filament or the cathode K which is fed through a battery B. From the battery B two branches run, one to the earth conductor E^1 and the other through battery B^1 and secondary coil 10 to the grid anode *g* in the vacuum tube. By the method of connections shown in dotted lines, a desired voltage at the grid electrode *g* may also be produced through the wire 17 which is branched off from the main current conductor through switches 16 and some small condensers (*a*, *b*, *c*, *d*) connected in series, and conductor 18, without the battery B^1 being required.

The action of the entire system is somewhat as follows:—

On the connecting conductor of the aerial collector network being short circuited to earth, the condenser pole 11 is charged and slightly damped oscillations are formed in the short circuited existing oscillation circuit formed of the condenser 11 and self inductance 9. In consequence of the coupling through coil 10, fluctuations of voltage take place in the grid circuit 15 with the same frequency, which, fluctuations in turn influence the strength of the electrode current passing through the high vacuum amplyfying tube and thus produce current fluctuations of the same frequency in the anode circuit. A permanent supply of energy to the oscillation circuits 9 and 10 consequently takes place, until a condition of balance is set up, in which the consumed oscillation energy is equal to that absorbed. Thereby constant undamped oscillations are now produced in the oscillation circuits 9–11.

For regular working of such oscillation producers high vacuum strengthening tubes are necessary and it is also necessary that the grid and anode voltages shall have a phase difference of 180° so that if the grid is negatively charged, then the anode is positively charged and vice versa. This necessary difference of phase may be obtained by most varied connections, for example, by placing the oscillation circuit in the grid circuit or by separating the oscillation circuit and inductive coupling from the anodes and the grid circuit and so forth.

A second important factor in this way of converting static atmospheric electricity into undamped oscillations is that care must be taken that the grid and anode voltages have a certain relation to one another; the latter may be obtained by altering the coupling and a suitable selection of the self induction in the grid circuit, or as shown by dotted lines 18, 17, 16 by means of a larger or smaller number of condensers of suitable size connected in series; in this case the battery B^1 may be omitted. With a suitable selection of the grid potential a glow discharge takes place between the grid *g* and the anode A, and accordingly at the grid there is a cathode drop and a dark space is formed. The size of this cathode drop is influenced by the ions which are emitted in the lower space in consequence of shock ionization of the incandescent cathodes K and pass through the grid in the upper space. On the other hand the number of the ions passing through the grid is dependent on the voltage between the grid and the cathode. Thus if the grid voltage undergos periodic fluctuations (as in the present case) the amount of the cathode drop at the grid fluctuates and consequently the internal resistance of the tube correspondingly fluctuates, so that when a back coupling of the feed circuit with the grid circuit takes place, the necessary means are afforded for producing undamped oscillations and of taking current, according to requirements from the collecting conductor.

The frequency of the undamped oscillations produced is with a suitably loose coupling equal to the self frequency of the oscillation circuits 9 and 10. By a suitable selection of the self induction of the coil 9 and capacity 11 it is possible to extend from frequencies which produce electromagnetic oscillations of only a few metres wave length down to the lowest practical alternating current frequency. For large installations a suitable number of frequency producing tubes in the form of the well known high vacuum transmission tubes of .5 to 2 kw. in size may be connected in parallel so that in this respect no difficulty exists.

The use of such tubes for producing undamped oscillations, and also the construction and method of inserting such transmission tubes in an accumulator or dynamo circuit is known and also that such oscillation producing tubes only work well at voltages of 1,000 up to 4,000 volts, so that on the contrary their use at lower voltages is

considerably more difficult. By the use of high voltage static electricity this method of producing undamped oscillations as compared with that through spark gaps must be regarded as an ideal solution particularly for small installations of outputs of from 1 to 100 kw.

By the application of safety spark gaps, with interpolation of electro-magnets, not only is short circuiting avoided but also the taking up of current is regulated. Oscillation producers inserted in the above way form a constantly acting electromagnetic alternating field in the collector coil, whereby as already stated, a considerable accumulating effect takes place. The withdrawal wire or working wire is connected at 12 and 13, but current may be taken by means of a secondary coil which is firmly or movably mounted in any suitable way inside the large collector coil, i. e. in its electromagnetic alternating field, so long as the direction of its axis runs parallel with that of the main current collecting coil.

In producing undamped oscillations of a high frequency (50,000 per second and more) in the oscillation circuits 9 and 11, electromagnets S and S^1 must be inserted if the high frequency oscillations are not to penetrate the collector coil, between the oscillation producers and the collector coil. In all other cases they are connected shortly before the earthing (as in Figs. 27 and 28).

In Figure 27 a second method of construction of the connecting conductor of the balloon aerials is illustrated in the form of a coil. The main difference consists in that in addition to the connecting conductor I another annular conductor II is inserted parallel to the former on the high voltage masts in the air (or embedded as a cable in the earth) but both in the form of a coil. The connecting wire of the balloon aerials is indicated as a primary conductor and also as a current producing network; the other is the consumption network and is not in unipolar connection with the current producing network.

In Figure 27 the current producing network I is shown with three balloon collectors 1, 2, 3 and aerial conductors 4, 5, 6; it is short circuited through condenser 19 and inductance 9. The oscillation forming circuit consists in this diagram of spark gap *f*, inductance 10, and condenser 11; the earth wire E, is connected to earth over electromagnet S^1. F is the safety spark gap which is also connected to earth through a second electromagnet S at E. On connecting up the condenser circuit 11 this is charged over the spark gap *f* whereby an oscillatory discharge is formed. This discharging current acts through inductance 10 on the inductively coupled secondary 9, whereby in the producing network a modification of the potential of the condenser 19 is produced. The consequence of this is that oscillations arise in the coil shaped producer network. These oscillations induce a current in the secondary circuit II, which has a smaller number of windings and a less resistance, the voltage of which, according to the proportion of the number of windings and of the ohmic resistance, is considerably lower whilst the current strength is greater.

In order to convert the current thus obtained into current of an undamped character, and to tune its wave lengths, a sufficiently large regulatable capacity 20 is inserted between the ends 12 and 13 of the secondary conductor II. Here also current may be taken without an earth conductor, but it is advisable to insert a safety spark gap E^1 and to connect this with the earth over an electromagnet S^2.

The producer network may be connected with the working network II over an inductionless condenser 21 or over an induction condenser 22, 23. In this case the secondary conductor is unipolarly connected with the energy conductor.

In Figure 28 the connecting conductor between the separate accumulator balloons is carried out according to the autotransformer principle. The collecting coil connects four aerial balloons 1, 2, 3, 4, the windings of which are not made side by side but one above the other. In Figure 28 the collector coil I is shown with a thin line, the metallically connected prolongation coils II with a thick line. Between the ends I^1 and II^1 of the energy network I a regulating capacity 19 is inserted. The wire I^1 is connected with the output wire and with the spark gap F.

As transformer of the atmospheric electricity an arrangement is employed which consists in using rotary pairs of condensers in which the one stator surface B is connected with the main current, whilst the other A is connected with the earth pole. Between these pairs of short circuited condensers are caused to rotate from which the converted current can be taken by means of two collector rings and brushes, in the form of an alternating current, the frequency of which is dependent on the number of balloons and the revolutions of the rotor. As the alternating current formed in the rotor can act, in this improved method of connection described in this invention, through coils 10 on the inductance 9, an increase or diminution of the feed current in I can be obtained according to the direction of the current by back induction. Current oscillations of uniform rhythm thereby result in the coil shaped windings of the producer net-work.

As the ends of this conductor are short cir-

cuited through the regulatable condenser 19 these rhythms produce short circuited undamped oscillations in the energy conductor, the periodicity and wave lengths of which oscillations can be adjusted according to desire by altering the capacity 19 to a given wave length and therewith also to a given frequency. These currents may also be employed in this form directly as working current through the conductors II^1 and III. By inserting the condenser 20 a connection between these conductors may also be made, whereby harmonic oscillations of desired wave length are formed. By this means quite new effects as regards current distribution are obtained. The withdrawal of current can even take place without direct wire connection if, at a suitable point in the interior of the producing network (quite immaterially whether this has a diameter of 1 or 100 km.) a coil tuned to these wave lengths and of the desired capacity is firmly or movably mounted in the aerial conductor in such a way that its axial direction is in parallel with that of the collector coil. In this case a current is induced in the producing network, the size of which is dependent on the total capacity and resistance and also on the periodicity employed. A possibility is thereby afforded in future, of taking energy from the producer network by wireless means. As thereby in addition to atmospheric electricity also magnetic earth currents and the energy from the higher atmosphere (at least partially) may be simultaneously obtained, this last system for collecting the atmospheric energy is of particular importance for the future.

Of course everywhere instead of spark gaps suitable grid vacuum tubes may be employed as producers for undamped oscillations. The separate coils of the producer net-work with large diameters may be connected with one another through separate conductors all in parallel or all in series or in groups in series. By regulating the number of oscillations and also the extent of the voltage more or less large collector coils of this kind may be employed. The coils may also be divided spirally over the entire section. The coils may be carried out in annular form or also in triangular, quadrangular, hexagonal or octagonal form.

Of course wires may be carried from a suitable place to the centre or also laterally which serve the current waves as guides. This is necessary when the currents have to be conducted over mountains and valleys and so forth. In all these cases the current must be converted into a current of suitable periodicity.

As already hereinbefore mentioned separate collecting balloons may be directly metallically interconnected at equidistant stations distributed over the entire country or may be connected by interpolation of suitable condenser batteries by means of high voltage conductors. The static electricity is converted through a spark gap into dynamic energy of a high number of oscillations, and could then in such form, with a suitable arrangement of the connections, observing various measures of precaution, be employed as source of energy after separate or special regulation.

According to this invention in order to increase the collecting effect of the balloon in the aerial collector conductor or in the earth wire, radiating collectors are employed. These consist either of incandescent metal or oxide electrodes in the form of vacuum grid tubes, or electric arcs (mercury and the like electrodes) Nernst lamps, or finally flames of various kinds may be simply connected with the respective conductor.

It is well known that energy can be drawn off from a cathode consisting of an incandescent body opposite an anode charged with positive electricity (vacuum grid tube). Hitherto however, a cathode was always first directly placed opposite an anode, and secondly the system always consisted of a closed circuit.

Now if we dispense with the ordinary ideas in forming light or flame arcs in which a cathode must always stand directly opposite an anode, and if we place an incandescent cathode opposite an anode charged to a high potential or another body freely floating in the air, or regard the incandescent cathode only as a source of unipolar discharge (which represent group and point discharges in electro-static machines similar to unipolar discharges), it may be ascertained that incandescent cathodes and less perfectly all incandescent radiators, flames and the like admit of relatively large current densities and allow large quantities of electric energy to radiate into the open space in the form of electron streams as transmitters.

The object of this invention is as described below, if such incandescent oxide electrodes or other incandescent radiators or flames are not freely suspended in space but connected metallically with the earth so that they can be charged with negative terrestrial electricity, these radiators possess the property of absorbing the free positive electrical charges contained in the air space surrounding them (that is to say of collecting them and conducting them to earth). They can therefore, serve as collectors and have, in comparison to the action of the spikes, or points, a very large radius of action R; the effective capacity of these collectors is much greater than the geometrical capacity (R_0–) calculated in an electro-static sense.

Now as our earth is surrounded as is well

known, with an electro-static field and the difference of potential

$$\frac{\delta V}{\delta h}$$

of the earth field according to the latest investigations, is in summer about 60 to 100 volts and in winter 300 to 500 volts per metre of difference in height (δh), a simple calculation gives the result that when such a radiation collector or flame collector is arranged for example on the ground, and a second one is mounted vertically over it at a distance of 2,000 metres and both are connected by a conducting cable, there is a difference of potential in summer of about 2,000,000 volts and in winter even of 6,000,000 volts and more.

According to Stefan Boltzmann's law of radiation, the quantity of energy which an incandescent surface (temperature T) of 1 sq. cm. radiates in a unit of time into the open air (temperature T_o) is expressed by the following formula:

$$S=\sigma\ (T^4-T^4_o)\ \text{watt/sq. cm.}$$

and the universal radiation constant σ is according to the latest researches of Ferry (Annales de Chimie et de physique 17 page 267 (1909)) equal to 6.30×10^{-12} watt/sq. cm.

Now if an incandescent surface of 1 sq. cm. shows, as compared with the surrounding space a periodic fall of potential δV it radiates (independent of the current direction, that is to say of the sign) in accordance with the above formula, for example at a temperature of 3725° C. an energy of 1.6 kw. per sq. cm. per second. As for the radiation the same value can be calculated for the collection of energy, but reversed. Now as carbon electrodes at the temperature of the electric arc support on the current basis a current density up to from 60 to 65 amperes per sq. cm. no difficulties will result in this direction in employing radiating collectors as accumulators.

If the earth be regarded as a cosmically insulated condenser in the sense of geometrical electro-statics *x* there results from the geometric (compare Ewald Rasch, "das elektrische Bogenlicht" (The electric arc light) page 169) capacity of the earth according to Chwolson:

For negative charging 1.3×10^6 Coulomb

For negative potential $V=10\times10^8$ volts. From this there results however, $EJT\cong24.7\times10^{24}$ watt/Sec. Now if it is desired to make a theoretic short circuit through an earthed flame collector this would represent an electric total work of about 79,500 10^{10} kilowatt years. As the earth must be regarded as a rotating mechanism which is thermo-dynamically, electromagnetically, and also kinematically coupled with the sun and stars system by cosmic radiations and gravitation a diminution of the electric energy of the earth field is not to be feared. The energies which the incandescent collectors would withdraw from the earth field can only cause by the withdrawal of motor work a lowering of the earth temperature (temperature $T_E=300$) and reduce this to that of the world space ($T=O$) by using the entire energy. This is however not the case as the earth does not represent a cosmically entirely insulated system. On the contrary there is conveyed to the same according to the recent value corrected by Ferry for the solar constants through the radiation from the sun an energy of $18{,}500\times10^{10}$ kw. Accordingly any lowering of the earth temperature (T_E) without a simultaneous lowering of the sun's temperature (T_S) would contradict Stefan Boltzmann's law of radiation.

$$S=\sigma\,(T_S^4-T_E^4).$$

From this it must be concluded that if the earth temperature (T_E) sinks, the total radiation S absorbed by the earth increases, and further also that the secular speed of cooling of the earth is directly dependent on that of the sun and the other radiators cosmically coupled with the sun and is connected most closely with these.

The incandescent radiation collectors may, according to this invention, be employed for collecting atmospheric electricity if they (1) are charged with the negative earth electricity (that is to say when they are directly connected by means of a metallic conductor with the earth) and (2) if large capacities (metal surfaces) charged with electricity are mounted opposite them as positive poles in the air. This is regarded as the main feature of the present invention as without these inventive ideas it would not be possible to collect with an incandescent collector, sufficiently large quantities of the electrical charges contained in the atmosphere as technology requires; the radius of action of the flame collectors would also be too small, especially if it be considered that the very small surface density (energy density) (σ about$=2\times7\ .\ 10^9$ St. E. per sq. cm.) does not allow of large quantities of charge being absorbed from the atmosphere.

x) Calculated according to Poisson's calculation;

$\Delta V=-4\pi\delta$; as here the alteration of the potential or potential gradients only takes place in the direction of the normal, this calculation assumes the simple form

$$\delta=\frac{1}{4\pi}\times\frac{\delta^2V}{\delta n^2}$$

It has indeed already been proposed to employ flame collectors for collecting atmospheric electricity and it is known that

their collecting effect is substantially greater opposite the points. It is however, not known that the quantities of current which could hitherto be obtained are too small for technical purposes. According to my experiments the reason for this is to be found in the too small capacities of the collector conductor poles. If such flame or radiating collectors have no or only small positive surfaces, their radius of action for large technical purposes is too small. If the incandescent collectors be constantly kept in movement in the air they may collect more according to the speed of the movement, but this is again not capable of being carried out in practice.

By this invention the collector effect is considerably increased by a body charged with a positive potential and of the best possible capacity being also held floating (without direct earth connection) opposite such an incandescent collector which is held floating in the air at a desired height. If for example, a collecting balloon of sheet metal or of metalized balloon fabric be caused to mount to 300 up to 3,000 metres in the air and as positive pole it is brought opposite such a radiating collector connected by a conductor to earth, quite different results are obtained.

The metallic balloon shell (with a large surface) is charged to a high potential by the atmospheric electricity. This potential is greater the higher the collecting balloon is above the incandescent collector. The positive electricity acts concentratedly on the anode floating in the air as it is attracted through the radiation shock ionization, proceeding from the incandescent cathode. The consequence of this is that the radius of action of the incandescent cathode collector is considerably increased and thereby also the collecting effect of the collecting balloon surface. Further the large capacity of the anode floating in the air plays therefore an important part because it allows of the taking of large charges, and thereby a more uniform current is obtained even when there is a large consumption: this cannot be the case with small surfaces.

In the present case the metallic collecting balloon is a positive anode floating in the air and the end of the earth conductor of this balloon serves as positive pole surface opposite the surface of the radiating incandescent cathode, which in turn is charged with negative earth electricity being conductingly connected to earth.

The process may be carried out by two such contacts (negative incandescent cathode and anode end of a capacity floating in the air) a condenser and an inductive resistance being switched on in parallel, whereby simultaneously undamped oscillations may be formed.

In very large installations it is advisable to connect two such radiating collectors in series. Thus an arc light incandescent cathode may be placed below on the open ground and an incandescent cathode which is heated by special electro-magnetic currents be located high in the air. Of course for this the special vacuum Liebig tubes with or without grids may also be employed. An ordinary arc lamp with oxide electrodes may be introduced on the ground and the positive pole is not directly connected with the collecting balloon, but through the upper incandescent cathode or over a condenser. The method of connecting the incandescent cathode floating in the air may be seen in Figs. 29–33.

B is the air balloon, K a Cardan ring (connection with the hawser) C the balloon, L a good conducting cable, P a positive pole, N negative incandescent cathode, and E earth conductor.

Fig. 29 represents the simplest form of construction. If electric oscillations are produced below on the ground by means of a carbon arc lamp or in other suitable way a considerably greater electric resistance is opposed to that in the direct way by inserting an electrical inductive resistance 9. Consequently between P and N a voltage is formed, and as, over N and P only an inductionless ohmic resistance is present, a spark will spring over so long as the separate induction co-efficients and the like are correctly calculated. The consequence of this is that the oxide electrode (carbon or the like) is rendered incandescent and then shows as incandescent cathode an increased collecting effect. The positive poles must be substantially larger than the negative in order that they may not also become incandescent. As they are further connected with the large balloon area which has a large capacity and is charged at high voltage, an incandescent body which is held floating in the air and a positive pole which can collect large capacities is thereby obtained in the simplest way. The incandescent cathode is first caused to become incandescent by means of separate energy produced on the earth, and then maintained by the energy collected from the atmosphere.

Fig. 30 only shows the difference that instead of a round balloon a cigar shaped one (of metal or metalized fabric) may be employed and also a condenser 5 is inserted between the incandescent cathode and the earth conductor so that a short circuited oscillation circuit over P. N 5 and 9 is obtained. This has the advantage that quite small quantities of electricity cause the cathode to become incandescent and much larger cathode bodies may be rendered incandescent.

In this form of construction both the in-

candescent cathode and also the positive electrode may be enclosed in a vacuum chamber as may be seen in Fig. 32. A cable L is carried well insulated through the cover of a vessel and ends in a condenser disc 5. The cover is arched in order to keep off the rain. The vessel is entirely or partially made of magnetic metal and well insulated inside and outside. Opposite the disc 5 another disc 6 and on this again a metallic positive pole of the vacuum tube *g* with the incandescent cathode (oxide electrode) N is arranged. The negative electrode is on the one hand connected with the earth conductor E, and on the other hand with the inductive resistance 9 which is also connected with the cable L with the positive pole and wound round the vessel in coils. The action is exactly the same as that in Fig. 29 only instead of an open incandescent cathode one enclosed in vacuo is employed. As in such collectors only small bodies can be brought to incandescence in large installations a plurality of such vacuum tubes must be inserted in proximity to one another. According to the previous constructions Figs. 31 and 33 are quite self evident without further explanations.

Figs. 34–37 represent further diagrams of connections over radiating and flame collectors, and in fact, how they are to be arranged on the ground.

Fig. 34 shows an arc light collector with oxide electrodes for direct current and its connection; Fig. 35 a similar one for alternating current, Fig. 36 an incandescent collector with a Nernst lamp and Fig. 37 a similar one with a gas flame.

The positive pole 1 of the radiating collectors is always directly connected to the aerial collecting conductor A. In Fig. 34 this is further connected over the condenser battery 5 with a second positive electrode 3. The direct current dynamo *b* produces current which flows over between the electrodes 3 and 2 as an arc light. On the formation of an arc the negative incandescent electrode 2 absorbs electricity from the positive poles standing opposite it and highly charged with atmospheric electricity and conveys the same to the working circuit. The spark gap 7, inductive resistance 9 and induction coil 10 are like the ones previously described. The protective electromagnet S guards the installation against earth circuiting, the safety spark gap 8 from excess voltage or overcharging.

In Fig. 35 the connection is so far altered that the alternating current dynamo feeds the exciting coil 11 of the induction condenser. 12 is its negative and 13 its positive pole; if the coil 3 on the magnet core of the dynamo is correctly calculated and the periodicity of the alternating current is sufficiently high an arc light can be formed between the two poles 1 and 2. As the cathode 2 is connected with the negatively charged earth, and therefore always acts as a negative pole, a form of rectification of the alternating current produced by the dynamo 3 is obtained, the second half of the period is always suppressed. The working circuit may be carried out in the same way as in Fig. 34; the working spark gap 7 may however be dispensed with, and instead thereof between the points *n* and *m* a condenser 5 and an induction resistance 9 may be inserted from which the current is taken inductively.

Fig. 36 represents a form of construction similar to Fig. 34 only that here instead of an arc lamp a Nernst incandescent body is employed. The Nernst lamp is fed through the battery 3. The working section is connected with the negative pole, the safety spark gap with the + poles. The working spark gap 7 may also be dispensed with and the current for it taken at 12 over the oscillation circuit 5, 11 (shown in dotted lines).

Flame collectors (Fig. 37) may also be employed according to this invention. The wire network 1 is connected with the aerial collector conductor A and the burner with the earth. At the upper end of the latter, long points are provided which project into the flame. The positive electrode is connected with the negative over a condenser 5 and the induction coil 9 with the earth.

The novelty in this invention is firstly, the use of incandescent cathodes opposite positive poles which are connected with large metallic capacities as automatic collecting surfaces, (2) the connection of the incandescent cathodes with the earth whereby, in addition to the electricity conveyed to them from the battery or machine which causes the incandescing, also the negative charge of the earth potential is conveyed, and (3) the connection of the positive and negative poles of the radiating collectors over a condenser circuit alone or with the introduction of a suitable inductive resistance, whereby simultaneously an oscillatory oscillation circuit may be obtained. The collecting effect is by these methods quite considerably increased.

I declare that what I claim is:—

1. An electrical energy generating system, comprising a conducting surface for static charges, means to support same at a distance above the earth, a conductor leading to the earth level, a spark gap associated with said conductor to convert electrostatic charges into electromagnetic high frequency oscillations means to supply said electromagnetic energy to a net work, and a spark gap of greatly increased relative resistance in parallel therewith.

2. An electrical energy generating system

comprising a conductor, means to support same above the earth level, an inductance therein, a spark gap associated with said conductor, a second spark gap of much higher relative resistance in parallel therewith and an energy receiving circuit coupled with the spark gap of lesser resistance.

3. An electrical energy generating system comprising a collecting surface, means to support same above the earth level, a conductor connecting said collecting surface with the earth level, a choke in said conductor, an electromagnetic resistance converting electrostatic energy to electromagnetic energy, a safety higher resistance in parallel therewith and a net work coupled with the conversion resistance of lesser value.

4. An electrical energy generating system comprising electric conductors spaced above the earth to form electromagnetic oscillating circuits, conductors connecting to earth level, electrostatic to electromagnetic energy conversion means therein, a safety high electrostatic resistance in parallel therewith and means to alter the electromagnetic characteristic of the circuits.

5. An electrical energy generating system comprising in combination a static collecting surface arranged above the earth, conductors connecting to earth level, a pair of spark gaps in parallel of different electrostatic resistance, a utilization net work shunted across the spark gap of lesser resistance and an electromagnetic choke in said conductors.

6. An electrical energy generating system comprising an open circuit energy collecting aerial, a pair of sparking gaps in parallel of widely different resistance, connected thereto and a closed electric oscillation circuit in shunt across the gap of lesser resistance.

7. An electrical energy generating system comprising an open circuit energy collecting aerial, a pair of sparking gaps in parallel of widely different resistance connected thereto, a closed electric oscillation circuit in shunt across the gap of lesser resistance, a plurality of electrostatic collecting surfaces, means to connect said collecting surfaces in parallel in groups and means to connect said groups symmetrically with said aerial.

In witness whereof, I have hereunto signed my name this 30 day of Dec., 1920, in the presence of two subscribing witnesses.

UNITED STATES PATENT OFFICE.

WALTER I. PENNOCK, OF PHILADELPHIA, PENNSYLVANIA.

APPARATUS FOR COLLECTING ELECTRICAL ENERGY.

1,014,719. Specification of Letters Patent. Patented Jan. 16, 1912.

Application filed January 4, 1911. Serial No. 600,777.

To all whom it may concern:

Be it known that I, Walter I. Pennock, a citizen of the United States, residing at Philadelphia, county of Philadelphia, and State of Pennsylvania, have invented certain new and useful Improvements in Apparatus for Collecting Electrical Energy, of which the following is a full, clear, and exact disclosure.

The present invention relates to an improved means for collecting the charges of electricity from the upper atmosphere and more particularly to that form which consists in one or more captive balloons from which is suspended a suitable form of metallic conductor.

The principal objects of the device are: to provide a collector for atmospheric and static electricity, which when in operative position will present a large surface to currents of air, but which will offer comparatively little resistance thereto, to provide a collector of such material and construction as will be more efficient in its operation than any previously constructed for a similar purpose, to provide a means for maintaining such a collector suspended in the air and at right angles to opposing currents thereof, and to provide a suitable anchorage for holding said means captive.

With these principal objects in view, the present invention consists in further advantages which are brought out in the following specification and accompanying drawings, in both of which like numerals refer to like parts, and in which drawings—

Figure 1 is a perspective view of the complete device in operative position, Fig. 2 is an enlarged detail view of the wire mesh and the manner in which it is attached to the supporting balloons, Fig. 3 is a detail of the manner of securing the collector-supporting and anchor cables to the balloons, Fig. 4 is an enlarged cross section of the swivel connection shown in Fig. 3, Fig. 5 is top plan view of the reinforcing braces on the screen, Fig. 6 is an elevation of the same and Fig. 7 is an end view of the structure shown in Figs. 5 and 6.

Referring to the drawings, in Fig. 1 thereof, a plurality of balloons 1 of any suitable type is shown, each of which embodies hollow metallic elongated gas tanks 2, extending from the rear of which are single, rigidly affixed rudders 3, while on the sides of the tanks are secured stationary lifting planes 4.

To the bottom and slightly to the rear of the center of the tanks 2 is secured a suitable swivel 5, by which the anchor ropes 6 and the suspension ropes 7 for the metallic conductor 8 are secured to the balloons 1. A suitable form of swivel joint is illustrated in Figs. 3 and 4, but any type can be used that embodies the essential features shown therein.

The swivel joint illustrated consists in the base plate 9 having a looped portion 10 integral therewith and projecting from the upper face thereof. Secured to the loop 10 is a set of three light electrically conductive supporting ropes or cables 11 which extend upwardly and are secured at intervals to the bottom 12 of the balloon above.

The lower or revoluble member 19 of the swivel joint preferably comprises three upwardly directed curved arms, 20, 21, and 22, respectively, forming at their junction a T-shape as shown, said arms at their upper extremities being integral with the plate 23. The member 19 is revoluble below and concentric with the plate 9, and the two members are lightened in weight by opposed concentric grooves as shown at 24. Contact between said members is made through the roller bearings 25, which are carried in the opposed concentric grooves 26 and 27 of the respective upper and lower plates. Furthermore, said plates are maintained in coöperative relation with each other by means of a bolt 28 passing through centrally drilled holes 29 and 30 in the respective lower and upper plates, the drilled hole 30 opening upwardly into an enlarged recess 31, in which is sunken the nut 32 on the bolt 28. Two of the arms 20 and 22 of the lower revoluble member 19 extend in diametrical alinement, while from the central point thereof extends the third arm 21 at right angles thereto, and upward to the plate 23.

Suspended below the plurality of balloons is a hollow rod 35, of any suitable material, connected at regular intervals such as at points 36, by metallic ropes 7, to the alined arms 20 and 22 of the swivel joint 5. Below and parallel to the rod 35 is a similar but smaller rod 38 suspended therefrom by means of suitable couplings 39. From the rod 38 hangs a wire mesh 40 of any suitable form, such as can be extended over a considerable area and which will offer comparatively little resistance to the passage of air therethrough. The metal in such a screen is preferably rough, sharp or jagged and a convenient form embodying these characteristics is expanded sheet metal such as is used for lathing and for reinforcing concrete construction. Instead of the single hollow rod 35 alone, applicant contemplates the use of reinforcing means to prevent the buckling of the rod in a stiff wind, such, for instance, as the arrangement of wire bracing shown in Figs. 5, 6 and 7 in which cross rods 41, secured to the rod 35 at the center thereof are attached to the ends thereof by means of stretched wires 42. Between the rods 41 and the ends of the rod 35 are secured sets of cross rods 43 which support the wires 42 and strengthen the rod 35 at as many points as they may be placed.

For the purpose of maintaining the balloons and apparatus suspended therefrom captive, the light metallic cables 6 terminating downwardly in insulators 45 are employed. These insulators in turn are connected by means of short sections of rope 46 to the eye 47 of a suitable swivel 48, embedded in the anchorage 49.

When the balloons with the metallic screen suspended therefrom are allowed to rise into one of the higher altitudes, the entire apparatus being of metallic construction and uninsulated will become energized by contact with the surrounding natural charges of electricity. From the above description it is evident then that, while the screen 8, on account of its great extent, will be the greatest collecting agent, it will be seen that the balloons themselves and the suspending wires will also coöperate as one large collector, since no parts of which are insulated from any of the neighboring parts thereof. Consequently, when the apparatus described has reached an altitude or strata of the atmosphere abounding in static charges of electricity, an amount of the said charges proportionate to the surface area of the metal exposed will collect upon the apparatus as a whole and will be conducted downwardly toward the earth by means of the various anchor ropes 6, but will not pass into the ground on account of the interposition of the insulators 45.

To use the electrical charges thus acquired, a plurality of Leyden jars 50, or other suitable collectors are supported above the surface of the earth and insulated therefrom by any suitable means as represented by the blocks 51. Either the inner or outer conducting surfaces of the jars may be connected together and energized by the accumulated charge. In the present instance, the inner surfaces of the accumulators are shown to be connected, and the connecting means 52 is in turn connected to the ropes 6 by means of wires 53. These wires are secured to the ropes mentioned by means of suitable binding posts 54.

In the device described the anchor ropes 6 are of substantially the same length, and when the apparatus is raised to the desired altitude and is being blown by the currents of air, the balloons are turned by means of the vanes 3 to parallel relation with each other, and furthermore, from the manner in which the device is held captive and the collecting net 40 is suspended from the balloons, it is obvious that said net will at all times readily swing into a plane substantially perpendicular to any current of air acting upon the balloons above. The purpose of the swivel joint shown in Figs. 3 and 4 is principally for allowing the balloons to readily aline themselves with any new direction of the wind before the apparatus, including the suspended screen, can swing about the swivel 48, and said joint will also prevent the twisting of the ropes 7, when any rapid shifting of the air currents may occur.

While applicant has shown a set of Leyden jars as the accumulators in the accompanying drawings, it is obvious that any other suitable form may be used, and furthermore, that although not illustrated, any suitable apparatus may be run thereby, such as for instance, wireless telegraphic instruments.

Furthermore, although but one embodiment of the invention has been described, it is to be understood that various modifications may be made therein, and in fact several are contemplated by applicant that are of such structure as fall well within the scope of the appended claim.

Having thus described my invention, what I claim and desire to protect by Letters Patent of the United States, is:

A collector for charges of electricity, comprising a plurality of supporting means, a metallic gauze sustained thereby to lie in a plane and substantially equidistant from each of said supporting means, anchoring means emanating from a common point to each of said supporting means, means operative to maintain said supporting means in their normal positions, and means between each of said supporting means and said gauze to permit each of said supporting means to readily and independently aline itself to accord with any alteration in the direction of opposing air currents.

In witness whereof I have hereunto set my hand this 28 day of December, A. D. 1910.

- **Аннотация:**

In this article possibility of transfer of electric energy and/or information to the object isolated from Earth or from other carrying-out body on one conductor, and short history of this question is discussed. Some electric circuits of such electricity transmission are given and it is defined to what physical mechanism (a single-wire electricity transmission), according to the author, corresponds. Attempt of calculation of the transferred power and relative loss of energy is made. The author gives possible ways of increase in power and reduction of losses, and also protection against an adverse effect of such electricity transmission on a human body. In article there is a description of the conducted experiments. Also in article it is possible to read what, according to the author, are possible areas of practical application, advantage and shortcomings of transfer of the electric power on one conductor. The author apologizes, that not all declared chapters are published. Subject very extensive, in essence, rather new area of electrical equipment while there is a work, he decided to take out that on court of readers that is already ready.

TABLE OF CONTENTS.

- Foreword.
- Chapter 1: The mechanism of single-wire transmission.
- Chapter 2. Calculation of the transmitted power.
- Chapter 3. * Efficiency single-wire transmission and possible protection against radiation.
- Chapter 4 Ways of increasing the transmission power.
- Chapter 5. A third method of single-wire power transmission
- Chapter 6. * Our experiments.
- Chapter 7. Possible uses a single-wire power.
- Literature.

* Chapters not ready (at work)

CHAPTER 1. MECHANISM OF A SINGLE-WIRE ELECTRICITY TRANSMISSION.

The first experiments on transmission of the electric power on one conductor were made at a dawn of formation of the theory of electricity at the end of the 18th century. It is possible to find the description of experience in which the charged full-sphere (transmitter) connects to the uncharged full-sphere (receiver) one conductor in any solid textbook of physics. On the uncharged full-sphere charges flow, it becomes the owner of electric potential and consequently also energies. But except as contribution to the theory of potentials and condensers, for development of the theory of a single-wire electricity transmission and practical use this experience then brought nothing.

In 1899 Nikola Tesla in laboratory about the town of Colorado Springs made brilliant experiment on transfer of the electric power on one conductor, he used Earth as such conductor. The lamps thrust to Earth were lit. On my understanding, he made it using, in some measure, the above described experience. Results were reflected in article in the 'Century Magazine', magazine under Robert Johnson's edition.

But, unfortunately, demonstrations of experiences are the limit, futher affairs did not progress. And it occurred, owing to circumstances, that not depend in him. Further this Titan put a problem more widely. He tried to find a way, and probably found, how to transfer the electric power to any given square of space in general without wires by means of resonance "swing" of an ionosphere. Made successful experiments in Uordenkliff. Therefore, he is a father of wireless transfer of the electric power which now too goes uphill.

Somewhere around 1981 I, then a young engineer working in one of the Soviet research institutes, in connection with the above experience from the textbook, came up with this idea. And what if you take 4 sphere and one conductor? See Figure 1.

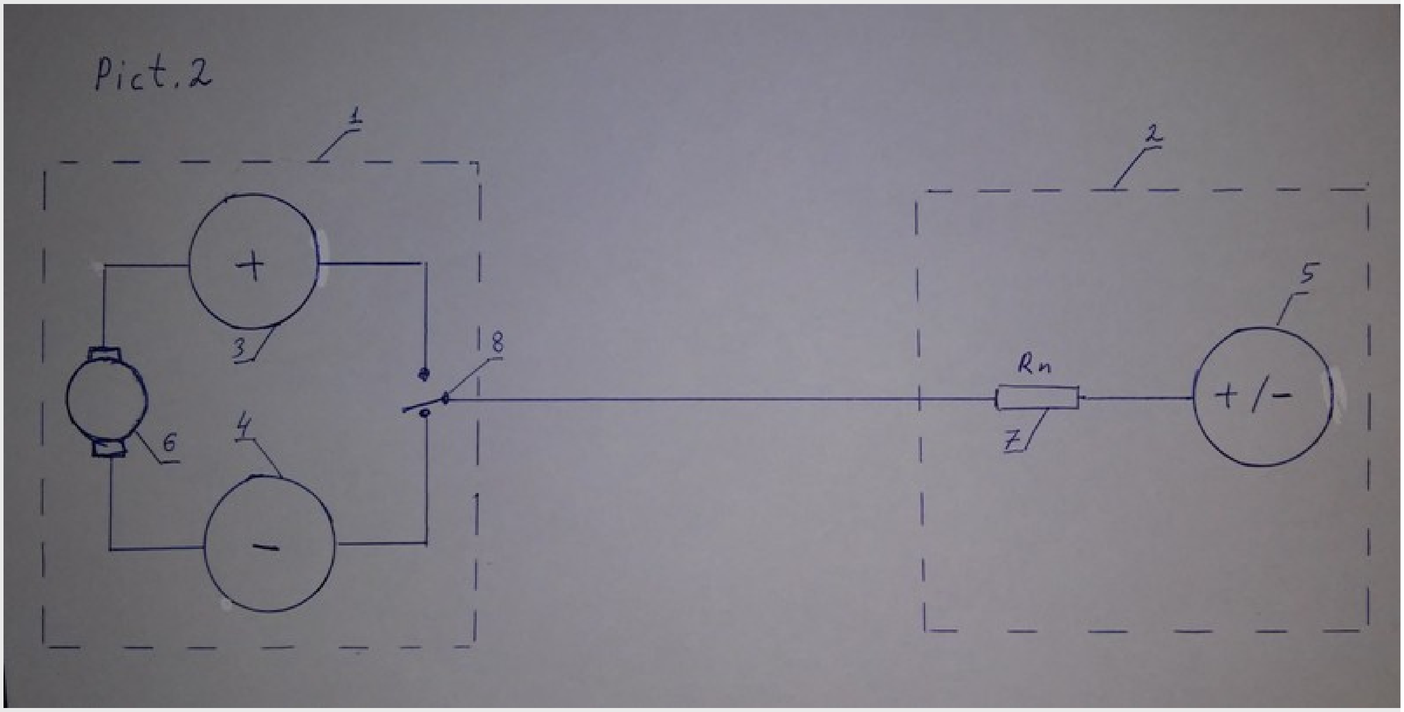
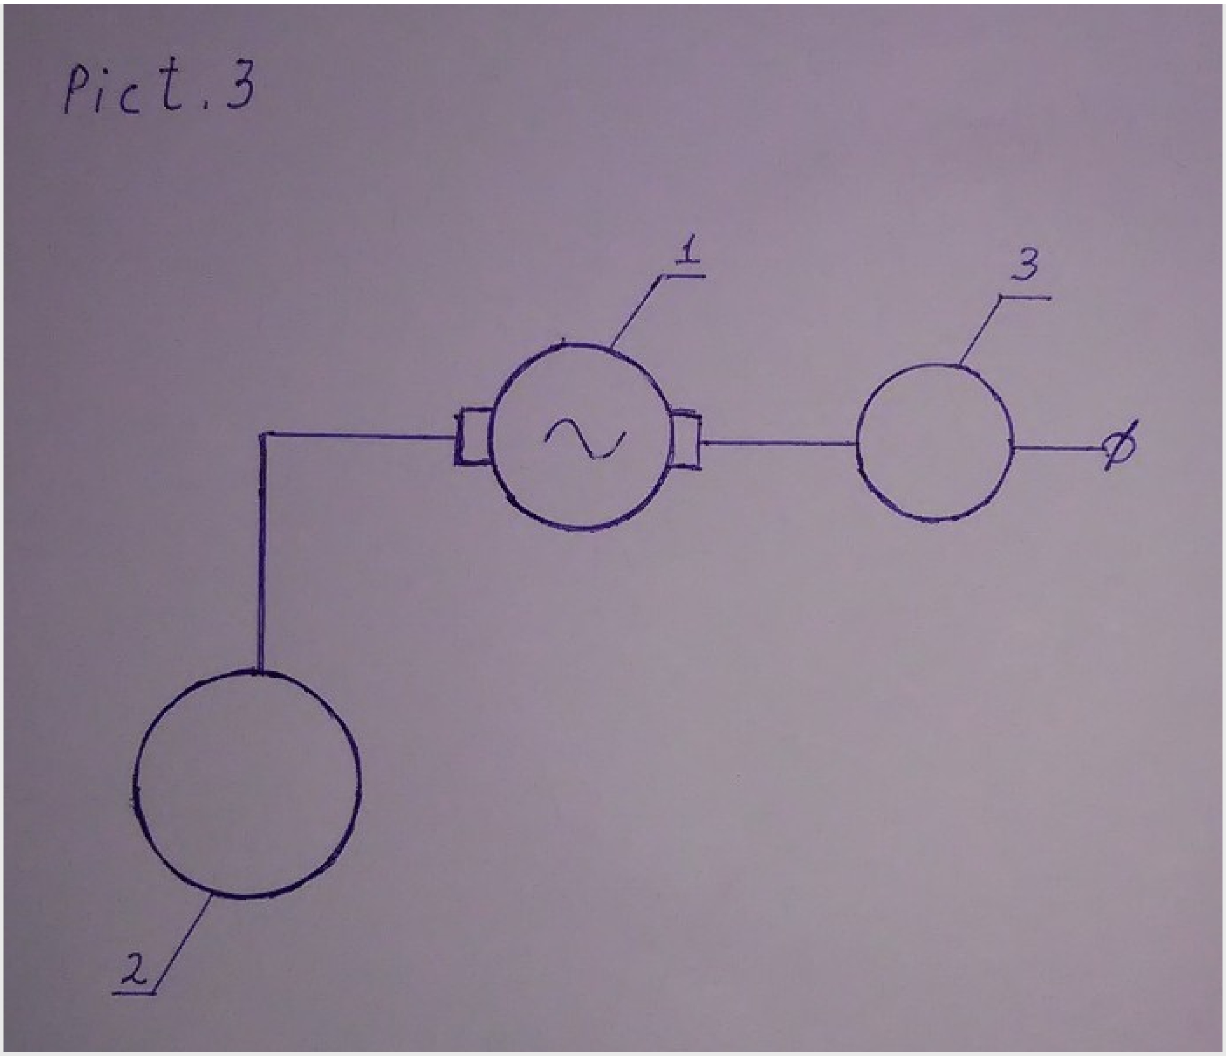
Two spheres (5 and 6) won't be loaded yet and to be on the receiver (2), and two loaded (3 and 4) one plus charges, and the second the minus - to belong to the transmitter (1). Then, working cyclically with switches (8 and 9), it is possible to connect in the first half of a cycle the same conductor the first loaded sphere (3) with not loaded (5), and in the second - the second loaded sphere (4) with another not loaded (6). Thus, at the end of a cycle we will receive two loaded spheres on the receiver, and charges can be removed from them through the payload (7), having involved the switch (11). We will feed transmitter spheres with charges all the time, having connected them, for example, to the battery, the generator of a direct current (10) or an influence machine. It is the first way of single-wire transfer. Subsequently, in operating time over this subject, also the second way, and simpler appeared. See Fig. 2.

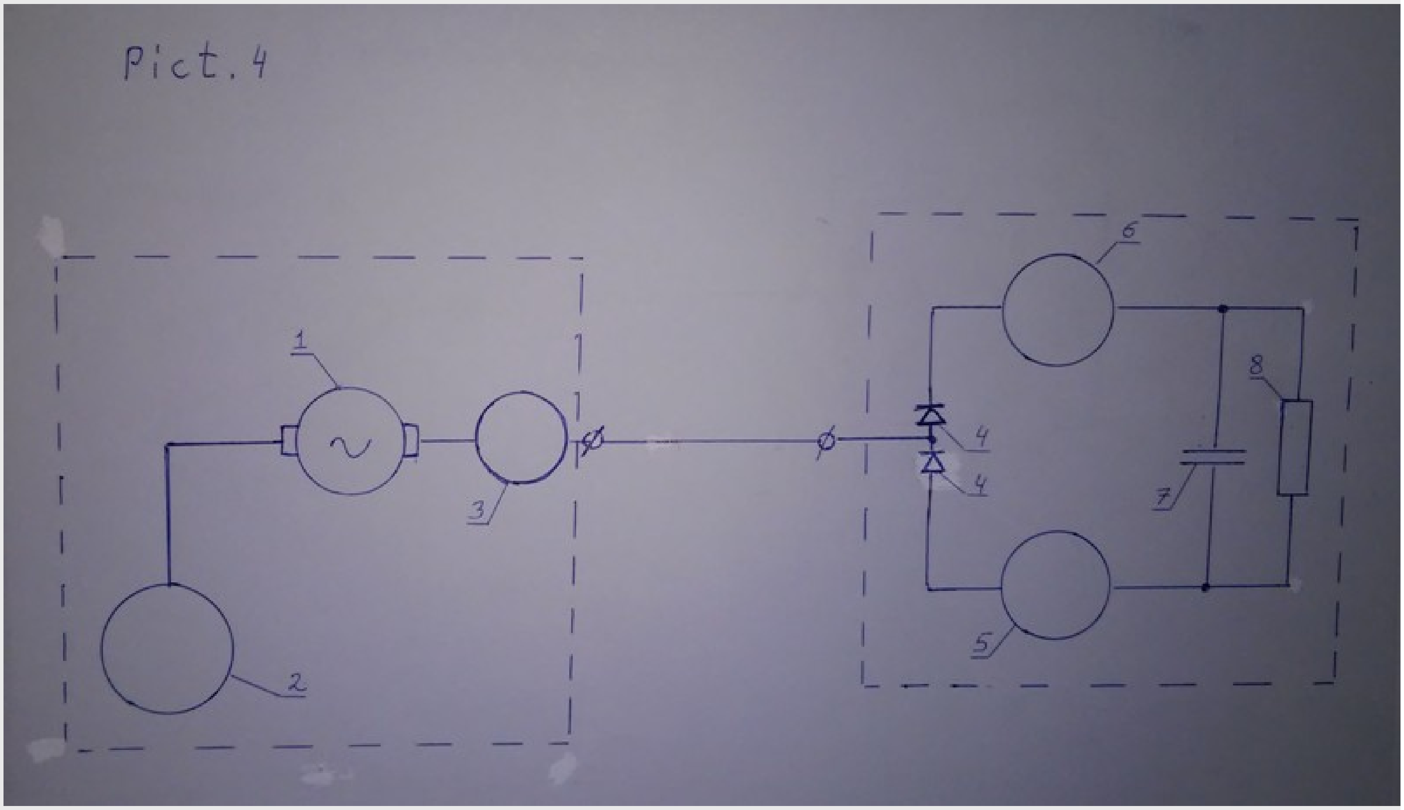


On the receiver (2) it is possible to leave only one store of electric charges(5) (in the text we will call spheres - stores of electric charges or it is simple - stores especially as stores aren't obliged to be a spherical form), but (7) we will place payload between it and the conductor going from the transmitter (1) now. Working with the switch (8), as well as at the first way, we connect alternately stores of the transmitter (3 and 4) to one conductor going to the receiver. The receiver store in each half-cycle of a cycle will receive charges of a different sign. And passing charges, every time a way from source stores to the receiver store, will make useful work, passing as well through load. Transmitter stores are recharged from the generator of a direct current (6) all the time. The continuity of transfer of current is provided to these. From the further text of article it will be clear that for the second way as load it is best of all to use, a winding of the transformer or an electric motor/electromagnet with the rectifier as thermal work won't be made. But if we want to receive, nevertheless, on the receiver heat on resistance, this resistance should be connected to a secondary winding of the transformer, and primary as it was told above, then to use as load.

Subsequently, for increase of overall performance and convenience, the scheme 1 and 2 underwent big changes. The transmitter in both schemes began to be the following device*.See Fig.3.

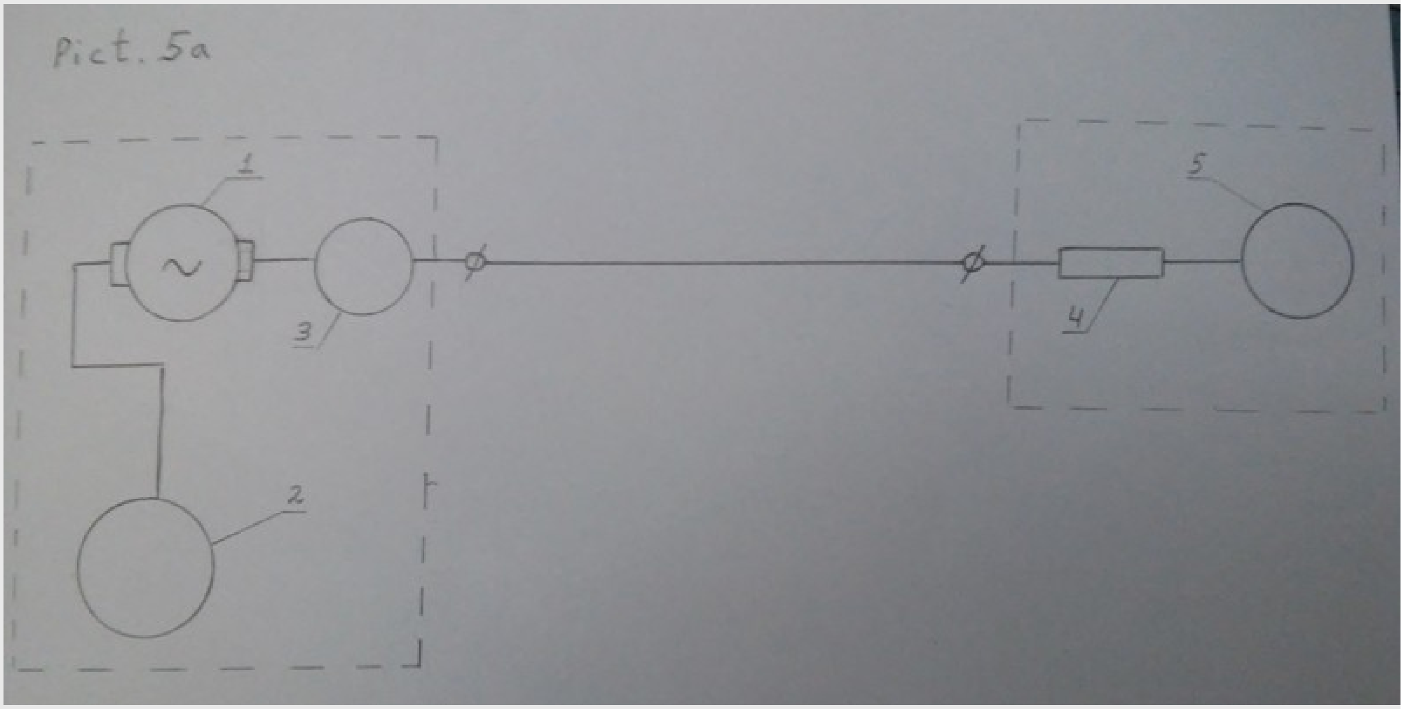


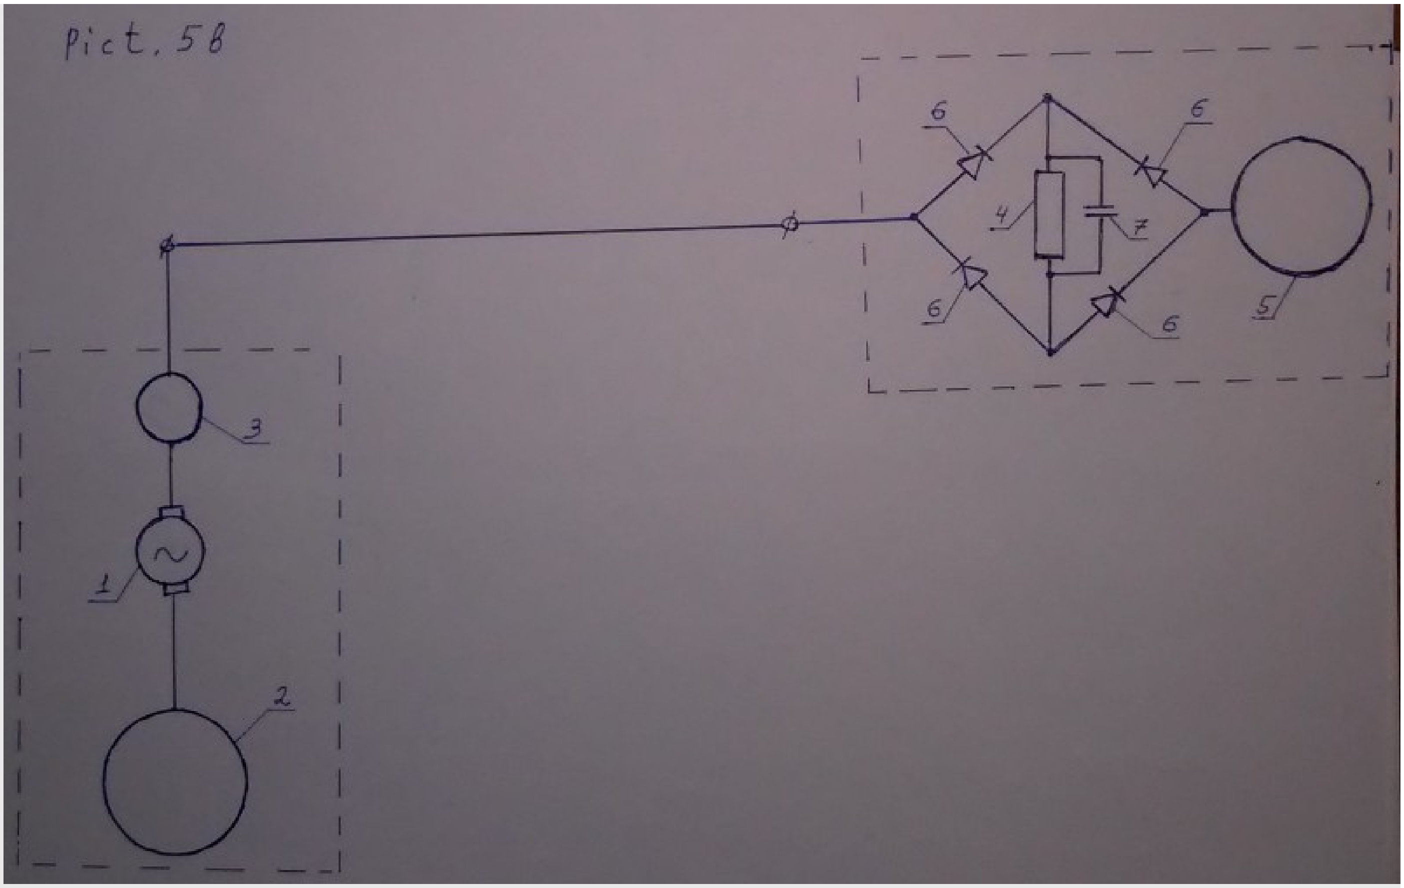
It is necessary to emphasize that here the generator of alternating current (1), but not constant already works. The store (3) transmitters from which charges for the conductor going to object of current supply not necessarily are removed has to possess big capacity, if receipt of charges from the generator continuously. In this case it can represent simply thin conductor. In case of faltering giving of charges from a source, its capacity has to be such that for a half-cycle not to allow essentially to fall to potential on it at "fence" of charges through the conductor on the receiver and interruptions in giving of charges from the generator. At such option its capacity and respectively the geometrical sizes, have to be at least 10 times more receiver store parameters. If interruptions small - that and the sizes modest. And here other store of the transmitter called in this article "buffer" (2), connected to its other conclusion even during the continuous operation of the generator has to possess rather big capacity and corresponding the big geometrical sizes. Its capacity has to be such that it at the set transfer of current potential (generator parameter) during a half-cycle could store so many charges of an opposite sign transferred, how many perceives the receiver store. That is in any way it isn't less than a capacity and according to the geometrical sizes of the store of the receiver. If it is more, it is only better. On Earth, a very good fit Earth itself - the spherical capacitor with huge geometric dimensions. That is, the second terminal of the generator, if conditions permit, the easiest way to ground **. The switch (9) in the first scheme (see Fig. 1) it was convenient to replace with a two diode switch 'diode fork' (4) (see Fig. 4).



The switch (11) (see Fig. 1) in the same scheme was not necessary.

So, we will consider the modified schemes. The scheme for the first way of an electricity transmission is submitted in Fig.4, and for the second in Fig.5a. In the first way, for the smoothing proceeding through loading (8) (see Fig.4) current, it is useful to connect the condenser (7) (see Fig. 4) parallel to this load. And as for the second way if we want that through load current of one direction began to flow, it is possible to use the diode bridge (6) (see Fig. 5b) and, besides, for smoothing to connect parallel to load (4) (see Fig.5b) the condenser (7) (see Fig.5b). This scheme is submitted in Fig.5b.





It is necessary to tell that as work on this subject didn't include in the plan of works of my scientific research institute, and I saw off it as a hobby, it moved ahead extremely slowly. During the researches I often went on consultation to Candidate of Physical Sciences Kirsanov Boris Petrovich and he made a big contribution to development of schemes and theories. In 1981/3 years I with Kirsanov B.P. submitted applications for inventions [5,6](photocopies at the end of the article). But experts of VNIIGPE didn't grant to us certificates, having referred to the low transferred power in our pilot unit executed according to the scheme of Fig. 4. But we experimental installation collected for the only purpose - to prove course of current in load, possibility of that was denied by experts absolutely at the first stage of ours with them communication. Then (in 1989) I with assistance of Kirsanov B. P. wrote article to the Inventor and Rationalizer magazine [1](photocopy at the end of the article). Soon after publication of my article it became clear that in parallel with us this subject is developed also by other people.

Group of inventors under the leadership of S. V. Avramenko under the auspices of Moscow Scientifically - Research Electrotechnical Institute collected and experienced installation on transfer of the electric power on one conductor [2,3]. This installation is very similar on thought up by us with Kirsanovy B. P. and published in the magazine [1]. In this article this installation is represented in Pict.4. They claimed that they made it before date of issue of our article. And that submitted the article to the same magazine, but didn't publish it. I won't argue with it. I will tell only, as at us before the publication installations too were collected and applications for inventions are submitted. I do not know how things are going with the priority, but that they are in the works, after our meeting and reading my article about something we have not mentioned, I think it ugly

As for their works, I think that they placed accents not there. Too great value was attached to a two diode switch 'diode fork' though the same results can be received and without it with synchronous switches. They worked (their installation) at very high frequency. Subsequently, from the text of this article it will be visible that it reduces efficiency of transfer and in general is harmful. But they collected very impressive pilot unit , I myself personally observed - it was possible to light the glow lamp.

Great merit of this group of people I see that they first drew attention to the fact that the single-wire transmission of electricity resistance of a conductor does not affect the transmit power. Furthermore, the transfer of electricity and do not affect the small gaps in the conductor cm. [4]. And I do not understand why these inventors have not submitted an application for discovery in the field of physics. As far as the physical process, it can be assumed that we are faced with a different mechanism of passing an electric current through a conductor. The charges are on the outer contour of the conductor, seeking to redistribute equipotentially throughout, even very distant surface. They do not go into the conductor and not get hit by the vibrating atoms of its crystal lattice. Nothing however retards the electrons and the conductor resistance is negligible regardless of its thickness and the material from which it is made. In experiments carried out in the writing of this article, such a property is supported by a series of experiments ... In addition, if the free electrons are facing a narrow "abyss" - a break in the conductor, the repulsion "accumulates" neighboring electrons helps them to "jump" through the "cleft" and "land" to "sparsely" surface.

As for later works, Kosinov N. V. article is interesting [2]. I consider this work among works of other authors the most advanced, it is possible to see the scheme very similar on presented on Pict.5b. Here for the first time, if to speak about works of other authors, in an explicit form there is a receiver store called for some reason "antenna". However, at such big frequency at which as I suspect, experiments and about which they for some reason "modestly are silent" were made, most likely it already radio frequencies, such name arises by itself. And that is "still interesting", about its (store) of a role in this work, for some reason, it is told nothing. And in general, looking through literature on this subject I see that as stores connecting wires, and authors of works, it seems, even serve don't guess their such function. Stores with small own capacity, like wires also will be suitable for high frequencies, but whether here it is worth working with high frequencies is a big question.

NOTES.

* For the elementary experiments as the transmitter it is possible to use one conclusion of the socket of the household power supply network, i.e. to insert one conductor into the right opening of the socket (it is a phase). But, as in a household network low frequency, current will go very small and it is necessary "to arm" for its registration with the microampermeter. It is possible to connect instead of the microampermeter the condenser / (plus the rectifier) and to load it some minutes then to pull together its connections wires and to observe a spark.

** Just the household network is grounded or connected to big electric capacitance.

CHAPTER 2. CALCULATION OF THE TRANSFERRED POWER.

Calculation is made for low frequencies of an electricity transmission. For high there will be differences. The main is that the geometrical sizes of stores of the receiver will cease to influence the accepted power as these conductive bodies won't manage to be filled for a half-cycle with charges. It is confirmed in work[10].

CALCULATION OF POWER FOR THE FIRST WAY OF A SINGLE-WIRE ELECTRICITY TRANSMISSION.

We will take an interval of time (t) equal to a half-cycle (t=T/2) of the frequency (nu) of switchings of the direction of a current of charges at a single-wire electricity transmission. This time throughout which the store of the receiver is connected by the conductor to the transmitter store possessing at this stage charges of some one sign, or "+" or "-". And these charges are redistributed so that to form an equipotential surface, i.e. charge the receiver store until electropotential on it isn't equal to transmitter store electropotential.

Stores, in all schemes provided in article are condensers which one facing is a surface of their physical body, and other- infinity. Therefore, according to a well-known physical formula for the condenser, we can write that the charged store possesses energy (W1), calculated on a formula (2.1).

(2.1) W1 = C x Phi squared/2

Where C - the electric capacity, Phi - potential.

While capacitor charging time (tau) is defined by (2.2).

(2.2) Tau = r x C, where r - resistance of the conductors going to the condenser.

As it was stated above, according to a series of experiments of N. (the same can be read and in works of other authors [2, 3]) follows that at a single-wire electricity transmission resistance of the conductors going to the store is insignificant a little. With what physical process it was possible to explain it, it is specified in Chapter 1. Therefore, it is insignificant a little and time of charging of the store (condenser). According to it, it is possible to fill a surface of the store which is on the receiver almost instantly. But what follows for calculation of the transferred power from here? And that we can reduce somehow time of a half-cycle (t) considered by us at calculations follows from this and respectively increase the frequency of an electricity transmission (nu), after all they are connected by a formula (2.3):

(2.3) nu = 1/T = 1/2t, or t = 1/2nu

the store of a receiver will always manage to be loaded in time = t.

The basic formula for the power (P1) says:

(2.4) P1 = W1/t Reducing (t) we increase the transferred power. We will substitute in a formula (4) expression for (t) from a formula (2.3). We will receive:

(2.5) P1 = 2 x nu x W1

So it is possible to draw a conclusion. The transferred power is directly proportional to the frequency of an electricity transmission (nu). Now question. To what level we can increase frequency? Restrictions "from above" following. At increase of frequency losses on the electromagnetic radiation of a wire grow, and they grow in proportion to not the first degree of frequency, as the power received by the receiver, and the second. We will deal with this issue in more detail later when we consider electricity transmission K.P.D. in Chapter 3. Besides, the high frequency and respectively strong electromagnetic radiation, can negatively affect in the medical plan the population of areas where the similar electricity transmission will be carried out. Too high frequency will be included into area of radio frequencies and will create hindrances of broadcasting and a special radio communication. Well and technical capabilities of the transmitter of the electric power, especially powerful, have some restrictions at creation of too high frequency.

Now we will consider other aspect. Influence of the geometrical sizes of the store , on the power received by this receiver. The best, in respect of the maximum electric capacitance at the minimum size, a form of the single store is a form of a sphere. After all at such form charges don't flow down from acute angles. But also other bodies with the carrying-out surface will accumulate charges. In calculations, nevertheless, as they have the general character, we will accept that we have a store of a spherical form. According to a well-known formula, the capacity of the spherical lonely condenser (C) it is equal:

(2.6) C = 4 x Pi x epsilon zero x R

Where epsilon zero - electric constant, and R - sphere radius. We will substitute this expression in a formula (1). We will receive:

(2.7) W1 = 4 x Pi x epsilon zero x R x Phi a square / 2, or after reduction: W = 2 x Pi x epsilon zero x R x Phi square

We will unite formulas (2.5) and (2.7) now and we will find expression for power.

(2.8) P1 = 4 x Pi x epsilon zero x nu x R x Phi square

We see that the transferred power P is proportional to the geometrical sizes of the store of the receiver (to sphere radius - R).

We will consider one more factor - electricity transmission potential. From the received formula (2.8) it is visible that the power of an electricity transmission P is proportional to the potential of Phi on the receiver store in the second degree. Now restrictions on potential. They are connected with safety of the people dealing with such electricity transmission and with loss of energy on the "crown" and leakage of electrons that we will consider later in Chapter 3. Later we will consider intake option where high potentials are only in its isolated part, and the current transfer conductor intended for it are under the usual not alternating (plus / minus) life-threatening potentials. Here it should be noted that though Nikola Tesla also opened that current of high frequency isn't dangerous to the person, if frequency is higher than 700 Hz in case of any potential, but there are sudden interruptions in electrical power supply, and also switching on and switch-offs. The pulses resulting from it can be very dangerous. Therefore, I believe ,that insulation is all the same necessary even if we will decide to work at high frequency.

One more aspect. The formula (2.8) is fair for vacuum and is only approximate for the air environment (where dielectric permeability is very close to unit). After all the formula (2.2) on which we base calculation is written for a lonely sphere in vacuum. If we surround the receiver store with a cover, the formula for power will be already another. Store capacity,and trasmited power, will raise if to surround it with the isolating cover with a big dielectric permeability (epsilon). We will remember a formula for the spherical condenser:

(2.9) C = (4 x Pi x an epsilon x an epsilon zero) / (1/a - 1/b),

where a - the radius of the internal sphere, b - the radius of the external sphere. Here, for example, a ferroelectric material has coefficient of dielectric permeability about 10 in the fourth degree. But it doesn't mean that power will increase in the corresponding number of times. It would be fair only for the two-superficial condenser where all space between facings is filled with dielectric. In our case, one facing is a surface of the store, and the second - infinity, and we can't fill all infinite space with dielectric. Therefore also dependence will be weaker.

Series of experiments of N... shows that the cover from material with big dielectric permeability positively influences amount of the energy transferred to the store. These researches aren't finished yet and within my laboratory conditions hardly in general will be qualitatively executed. But so far all of us can accept that the transferred power depends on thickness of a cover of the store of the receiver and on dielectric permeability of material of which it is made. We will reflect it in a new formula.

(2.10) P1 = K1 x f (d, epsilon) x nu x R x Phi a square

Where:

K1 - coefficient , approximately equal (as not all stores of receivers will be the correct spherical form) 4 x Pi x epsilon zero. K1 is approximately equal = 1.11 x 10 to the minus tenth degree.

f - function, with parameters: d - receiver store cover thickness, an epsilon - dielectric permeability of material of which the cover is made. f > 1.

So, we "will sound" a final formula. Power of single-wire transfer grows in proportion to a potential square on the line, transmission frequency and to the sizes of stores in the first degree and it is influenced positively by the isolating cover of stores (the more thickness and dielectric permeability of material, the better).

It was calculation for the first way of a single-wire electricity transmission. We will consider as affairs with a power for the second way are.

CALCULATION OF POWER FOR THE SECOND WAY OF A SINGLE-WIRE ELECTRICITY TRANSMISSION.

We will define the energy received by object for a half of the period of fluctuations of potential on a power line. It is natural that all this energy is spent in the load located between a transmission line and the store. Work (A) of movement charges (Q) in electric field is defined by a formula:

(2.11) A = Q x deltaPhi ,

where deltaPhi - a potential difference of the store of object and the line. To start any half-cycle of transfer, on the line and on the store there will be potentials of a different sign, each of which on the module is equal to Phi. Potential difference

deltaPhi = Phi-(-Phi) =2Phi.

But, in process of leakage of charges from the store and their passing through the load, potential on the store, we will call it (Phi2) changes therefore deltaPhi is function of quantity of charges on the store. We will write down it so:

deltaPhi = F(Q)

Potential on the line at the movement of charges won't change, as annihilation of charges which now on the line, from revenues to the line of charges of other sign, all the time is compensated by giving to the line charges from the generator.

From the point of view of power, process of passing of electrons through load can be divided into two stages. The first stage where work (A1) will be made - this movement of all charges from the receiver store (we will assume negative charges) through the load to a power line. This process happens to a total disappearance of charges of this sign on the store and, according to it, transformation of its potential into the zero. The second stage where work (A2) - this passing through load of charges from the line will be made (in our example positive) to the receiver store before establishment of potential on it (positive) equal to the potential on the line. Thus, the general work or energy (that in this case the same) which is obtained for a half of the period on the load:

(2.12) W2 = A1 + A2

Despite the fact that we are talking here about the two stages of the process, in fact, in terms of movement of electrons - it is continuous, and the electrons will flow in one direction only. It's just a matter of determining the sign of the charge.

Let's try to calculate the work A1.

Elementary work (its differential) will be equal to the multiplication of the potential difference deltaPhi on the elementary charge (differential Q).

(2.13) dA1 = deltaPhi (Q) x dQ = F(Q) x dQ

As already mentioned above, the potential difference is a function of the charge on the store F(Q). Let's see how this function can be expressed. With the leakage of charges through the load, it decreases. The potential of the store (Phi2) is determined by the following formula.

(2.14) Phi2 = Q / C, then

(2.15) F(Q) = Phi - (-Fi2) = Phi + Fi2 =Phi + Q / C

Substituting this expression into (2.13), we obtain:

(2.16) dA1 = (Phi + Q / C) x dQ

In order to define work A1, we have to take the integral of the expression within the following limits: lower = 0, and the top, equal to the maximum (initial) charge that is Qmax = C x Phi. After the corresponding calculations which are excessive for bringing here, we will receive:

(2.17) A1 = Phi square x C + Phi square x C / 2

Now let's calculate the A2.

Work or energy of movement of charges, as well as for A1, is determined by a formula (2.11). The potential difference between the line and the receiver store (deltaPhi) is also a function of the charge on this store. Let's see how in this case is defined F (Q). During all process, including at its beginning, potential on the line = Phi. Phi2 store potential is equal in the beginning 0, but in process of receipt on it charges which pass a way from the line through load, potential grows. Phi2 is defined by a formula (2.14). Its final value will be Phi. For a potential difference or F(Q) the following formula has to be fair.

(2.18) F(Q) = Phi - Phi2 = Phi - Q/C

Elementary work (dA2) is defined by a formula (2.13). We will substitute in it the expression which is just received by us for a potential difference, i.e. a formula (2.18). We will receive:

(2.19) dA2 = (Phi - Q/C) x dQ

In order to define work A2, we have to take the integral of the expression within the following limits: lower = 0, and the top, equal to the maximum (final) charge that is Qmax = C x Phi. After the corresponding calculations which are excessive for bringing here, we will receive:

(2.20) A1 = Phi square x C - Phi square x C / 2

To find the general work or energy emitted on load for a half of the period of an electricity transmission (W2) we substitute A1 and A2 values in a formula (2.12). We will receive:

(2.21) W2 = Phi square x C + Phi square x C/2 + Phi square x C - Phi square x C/2 = 2 x Phi square x C

We will compare this formula to a formula (2.1) for the first way and we will see that the energy for a half period received by the object of a current supply at the second way grew by 4 times. We can write down.

(2.22) W2 = 4 x W1

As all the rest in calculation of power remains the same, it is possible to write down that the power (P2) too grew by 4 times. Besides, at the second way we receive "bonus" - it isn't necessary to have two stores on the receiver, only one and the same size.

(2.23) P2 = 4 x P1

We can write for the second method, the formula similar to the formula (2.10), only take into account the increase in the power coefficient. K2 = K1 x 4 or approximately equal to 4.44 x 10 in -10 degrees. So, power for the second way is expressed by a formula:

(2.24) P2 = K2 x f (d, epsilon) x nu x R x Phi square

CHAPTER 3. EFFICIENCY OF SINGLE-WIRE TRANSMISSION AND POSSIBLE PROTECTION AGAINST RADIATION.

Efficiency of power transmisson can be defined as follows:
Efficiency = (received power / power line input) x 100%
We introduce the notation:
Pr - received power of the receiver.
Pl - losses in the power transmission process.
Power line input= Pr + Pl
Now the expression for the efficiency can be rewritten as follows:
(3.1) Efficiency = (Pr / (Pr + Pl)) x 100%
For ease of calculation, let's divide the numerator and denominator of this formula on the Pr.
(3.2) Efficiency = (1 / (1 + Pl / Pr)) x 100%
Let's denote the ratio Pl / Pr as the alfa,
alfa = Pl / Pr ,
Then formula (3.2) is as follows:
(3.3) Efficiency = (1 / (1 + alfa)) x 100%

We see that change of all function completely depends on changes of a ratio of Pl / Pr= alfa. For ensure of high efficiency, "alfa" shall aim to 0, then efficiency will be hundred percent. How to calculate the "Pr" (the power received by the object receiver) we set in chapters 2 and 5, it is possible to look at formulas (2.10), (2.24) and (5.26). As for "Pl", here we can be guided by the following provisions.

a) Losses on corona discharge and electron leakage. Because of the relatively low voltage on the line (we have introduced this limit for safety reasons), the corona discharge is not possible, and electron leak is very small, and these losses cannot be taken into account.

b) Heating the wire losses - are virtually absent, since it has no resistance to the motion of electric charges. This has been repeatedly described above.

c) Losses on the mechanical oscillation of the conductor. (Repulsion from the magnetic field of the Earth). These losses are due to their insignificance cannot be taken into account (after all, small currents).

g) Losses from radiation of electromagnetic waves.

This is the main power losses in this method of transmission.

Every conductor with alternating current radiates electromagnetic waves, and with increasing frequency energy emitted waves increases sharply (in proportion to the square of the frequency). Electromagnetic waves permanently move away from the wire, and therefore the energy consumption of the radiation waves are the transmission system losses. The radiated energy depends on the amplitude and frequency of current as well as the length of the conductor. The total average power "Nav" emitted by segment conductor with current (short antenna), in which the length "L" is much smaller than the wavelength, is equal to [12]:

(3.4) Nav = Mu zero x L square x Omega in a square x I in a square / (12 x Pi x C) where
Mu zero - a magnetic constant
Mu zero = 4 x Pi x 10 in minus 7 degrees
Pi - constant = 3.14
Omega - frequency
I - maximum current
C - light velocity.

Substituting in this formula the values of the coefficients and the speed of light, and taking into account that Nav = Pl , and the frequency in our article was usually designated as "nu", it is possible to re-write it in the following form:
(3.5) Pl = 1.11 x 10 at minus 16 degrees x L square x nu in square x I in the square

LET'S DERIVE THE FORMULA FOR "ALFA" IN THE SECOND TRANSMISSION METHOD.

Here we give the power received by the receiver of the object "Pr". For the second transmission method, we derived a formula for it in Chapter 2, this is formula (2.24)
(2.24) P2 = K2 x f (d, epsilon) x nu x R x Phi square
Where
f - function, with parameters: d - thickness of the shell of the collector of the receiver, epsilon - dielectric permeability of the material from which the shell is made. f > 1.
R - is the radius of the receiver store
Phi - is the potential on the transmission line
K2 - is approximately equal to 4.44 x 10 at minus 10 degrees. (K2 = 4 x K1)
We replace "P2" by "Pr" , then the formula (2.24) takes the following form:
(3.6) Pr = K2 x f (d, epsilon) x nu x R x Phi square

In order to write the relation of formulas (3.5) and (3.6), we must reduce them to uniformity. For this, we express the current "I" in (3.5) in terms of other parameters.
(3.7) I = Q / (T / 2),

Where "T" is the power transmission period (of the line potential change). Since the frequency nu = 1 / T, formula (3.7) can be rewritten in the following form.

(3.8) I = 2 x nu x Q

"Q" can be expressed through the capacity of the receiver store and the potential on the power line.

(3.9) Q = C x Phi

here C = K1 x f (d, epsilon) x R (watch Gl.2 formulas (2.9) and (2.10))

we will rewrite a formula (3.8).

(3.10) I = 2 x K1 x nu x f (d, epsilon) x R x Phi

Substitude the derived value for "I" in a formula (3.5). We will receive

(3.10) I = 2 x K1 x nu x f (d, epsilon) x R x Phi

Substitude the derived value for "I" in a formula (3.5). We will receive

(3.11) Pl = 1.11 x 10 at minus 16 degrees x L square x nu in the fourth degrees x 4 x K1 x K1 x f (d, epsilon) x f (d, epsilon) x R x R x Phi x Phi

Recalling that K2 = 4 x K1, we give here the formula for the received power, the transformed formula (3.6):

(3.12) = 4 x K1 x f (d, epsilon) x nu x R x Phi square

Now we can write a formula for "alfa", which is the ratio of the right-hand sides of formulas (3.11) and (3.12).

(3.13) alfa = Pl / Pr = K1 x 1.11 x 10 in minus 16 degrees x L square x nu in the third degrees x f (d, epsilon) x R

We substitute here the value for K1 = 1.11 x 10 in minus 10 degrees.

(3.14) alfa = 1.23 x 10 in minus 26 degrees x L square x nu in the third degrees x f (d, epsilon) x R

WE WILL DERIVE THE FORMULA FOR "ALFA" IN CASE OF THE THIRD METHOD OF THE ELECTRICITY TRANSMISSION.

Here 'I' for the formula (3.5) will be defined as follows.

(3.15) I = 2 x nu x Q

this formula is similar to formula (3.8) for the second method, but 'Q' for the third method is defined differently.

(3.16) Q = C x (Phi m + Phi l),

Where 'Phi m' is the potential of the charging device (an electrostatic machine), And 'Phi l' is the potential on the transmission line (corresponding to 'Phi' for the second method).

The formulas for capacity are similar

C = K1 x f (d, epsilon) x R

We write the expression for the current:

(3.17) I = 2 x K1 x nu x f (d, epsilon) x R x (Phi m + Phi l)

We substitute 'I' in the formula for the lost power (3.5) with this expression. We get:

(3.18) Pl = 1.11 x 10 at minus 16 degrees x L square x nu in the fourth degrees x 4 x K1 in the square x f (d, epsilon) in the square x R in the square x (Phi m + Phi l) in the square

Now we give here the power received by the receiver of the object 'Pr'. For the third electricity transmission method, we derived a formula for it in Chapter 5, this is formula (5.26)

(5.26) Pr = 2 x nu x K1 x f (d, epsilon) x R x Phi l x (Phi m + Phi l)

Now we can write a formula for alfa, which will be the ratio of the right-hand sides of formulas (3.18) and (5.26).

(3.19) alfa = Pl / Pr = 2 x K1 x 1.11 x 10 at minus 16 degrees x L square x nu in the third degrees x f (d, epsilon) x R x (Phi m + Phi l) / Phi l

We substitute here the value for 'K1' = 1.11 x 10 in minus 10 degrees.

(3.20) alfa = 2.46 x 10 in minus 26 degrees x L square x nu in the third degrees x f (d, epsilon) x R x (Phi m + Phi l) / Phi l

Since the third method of single-wire transmission requires an electrostatic machine, a battery and a DC motor in the receiver, we must also take into account their efficiency. And since the efficiency of the battery and the motor is rather low, on the average 85 and 83 percent respectively, then they, and not the calculated efficiency on the basis of radiation losses, will determine the efficiency of the third method of electricity transmission. We will see this, considering the calculation of the example given in this chapter.

Mean values:

DC motor efficiency = 83%

Battery efficiency = 85%

Efficiency of the electrostatic machine - it was not possible to find the value in the literature. However, what I want to note: if you do not take into account the friction of the brushes (in a large machine, this is a miser), then the main losses will go to the friction of the discs about the air. Leakage charges will be small due to the intended isolation of the stores. There are no braking force fields in the machine, so the efficiency will be high.

Recall the preliminary condition of these calculations: 'L' must be much smaller than the length of the radiated wave.

We will provide the table of lengths of waves "VL" and the frequencies "Fr" corresponding to them here. VL and Fr are related by the following relationship: Fr = c / VL, where C is the speed of light.

Fr, Hz----------VL, m
100 Hz------ - 3 000 000 m
1000 Hz (1 KHz)--------------300 000 m
10000 Hz (10 KHz)----------------30 000 m
100000 Hz (100 KHz)-------------------3 000 m
1000000 Hz (1 MHz)-------------------300 m

EXAMPLES.

EXAMPLE N1

Suppose we have a working room with robots that receive electricity for their work. We will use the third method of electricity transmission. The room is equipped with an electrically conductive floor, and the robots themselves contain electric receiver and built- in electric intakes that comes into contact with the floor. The floor measures 100 x 100 m. Transmitters will be on the edges of the floor. Then L max = 100m. In order to comply with the above condition, i.e. L (antenna length) should be much smaller than the wavelength of the radiated wave-VL. Assume that VL min = 1000m (ten times more than L max). Let's calculate Fr max , it will be 300 kHz. Let the geometric dimensions of receiver's stores in robots be real and amount to 1 m in diameter. We use the existing Vimschurst electrostatic machine. The electrical potential on the receiver's stores (with insulating sheath) will be equal the potential on this machine and will be 300 kV. The voltage on the power line (and this is the floor), we agreed to use only safe for life and equal to 220 V.

Let's answer the following questions:
1) What maximum power can be transmitted to each robot ?
2) What is the efficiency of the power line ?

To answer the first question, let us use the formula derived by us in Ch. 5, which determines the power transmitted by the third method of transmission. This is the formula (5.26)

(5.26) P3 = 2 x Nu x K1 x f (d, epsilon) x R x Fl x (FM + FL)

Where:

K1 - coefficient , approximately equal (as not all stores of receivers will be the correct spherical form) 4 x Pi x epsilon zero. K1 is approximately equal = 1.11 x 10 to the minus tenth degree.

f - function, with parameters: d - receiver store cover thickness, an epsilon - dielectric permeability of material of which the cover is made. f > 1.

R- is the radius of the store. In our example it is 0.5 m.

Fl is the potential on the transmission line (its absolute value), in this case, equal to 220V.

Fm is the potential on an electrostatic machine or some other device of an object receiver that recharges its drives (also its absolute value). In this example, equal to 300kV.

Nu is the frequency equal to Fr max = 300 kHz.

We substitute these values in the formula. We get P3 = 2199.4 W or about 3 horsepower. Thus, we will be able to give the robots enough power.

Now let's compare what would have happened if we had used the second method of electricity transmission. The formula for the transmitted power for this method was derived in Ch.2. This is the formula (2.24).

(2.24) P2 = K2 x f (d, epsilon) x nu x R x Phi square

Where:

f - function, with parameters: d - thickness of the shell of the collector of the receiver, epsilon - dielectric permeability of the material from which the shell is made. f > 1.

R- is the radius of the reciever store. In our example it is 0.5 m.

Phi - is the potential on the transmission line

Phi = Fl = 220 V

K2 - is approximately equal to 4.44 x 10 at minus 10 degrees. (K2 = 4 x K1)

Nu is the frequency equal to Fr max = 300 kHz.

We substitute these values in the formula. We obtain P2 = 3.22 W, i.e. Incomparably less transmitted power.

CHAPTER 4. WAYS OF INCREASING THE TRANSMISSION POWER.

Goal is - to create a single-wire electricity transmission, powerful, safe for a human body, at the small sizes of a current collector and at high efficiency and low cost.

Chapter 2 has a formula of power. Frequency and potential increase power, but as it was already specified, there are restrictions. High frequency reduces efficiency creates strong electromagnetic radiation and hindrances, and a lot of potential on the line may cause a fatal electric shock. In each case it is necessary to define the maximum potential on the line, and the maximum transmission frequency. In some cases, we will be ready to sacrifice high efficiency for increasing transmission power. For example, if the line goes through the taiga or in the desert, and the potential can be increased by high-frequency interference and electromagnetic radiation will not cause much harm, if you set the warning signs. But in the city it's different. In some cases, for example for electric transport transmission line should be no isolated because of the current collectors, respectively, and the potential to be safe. If the transmission line very long, too high frequency can lead to that charges for a half of a half-cycle won't manage to reach the store the receiver as a long wire has inductance which will work for delay. It can be explained from the point of view of the theory of an electrical oscillating circuit. In this case we have a sequential oscillating circuit with the certain natural frequency determined by values of capacity and inductivity. Capacity is a capacity of the receiver store (depends on the geometrical sizes), and inductivity is defined by length of a wire (line). It is known that the largest amplitude will be when the stimulated frequency (transmitter generator frequency) is equal to the natural frequency of a circuit determined by Thomson's formula. When the stimulated frequency is greater than the natural frequency, the value of the transmitted current decreases. A long wire has a large inductivity and will decrease natural frequency of the circuit. With the usual current transmission for small distances and with small geometric dimensions of the drives, we are always "not reaching" to the natural frequency of the circuit, therefore, as the frequency increases, the transmitted power increases, as shown earlier in Chapter 2.

Store capacity and consequently also transfer power, will increase if to surround it with the isolating cover with a big dielectric permeability (epsilon). In each case we define what material, firm or liquid will suit us depending on high cost, technical capabilities of performance and the demanded isolating properties.

Possible to use different physical effects and devices to increase the amount of charge received at halftime (of frequency period). According to the author, suitable Hall effect (the author has even experimental design in this area) and "Stop revolving coil" - as it was first used in the experiments L.I.Mandelstam and N.D.Papaleksi and later in experiments R.CH.Tolman T.D.Stewart.

The author has planned some more improvements (for example poly-cascade electric circuits) of an electricity transmission (increase in power) which need the experimental verification.

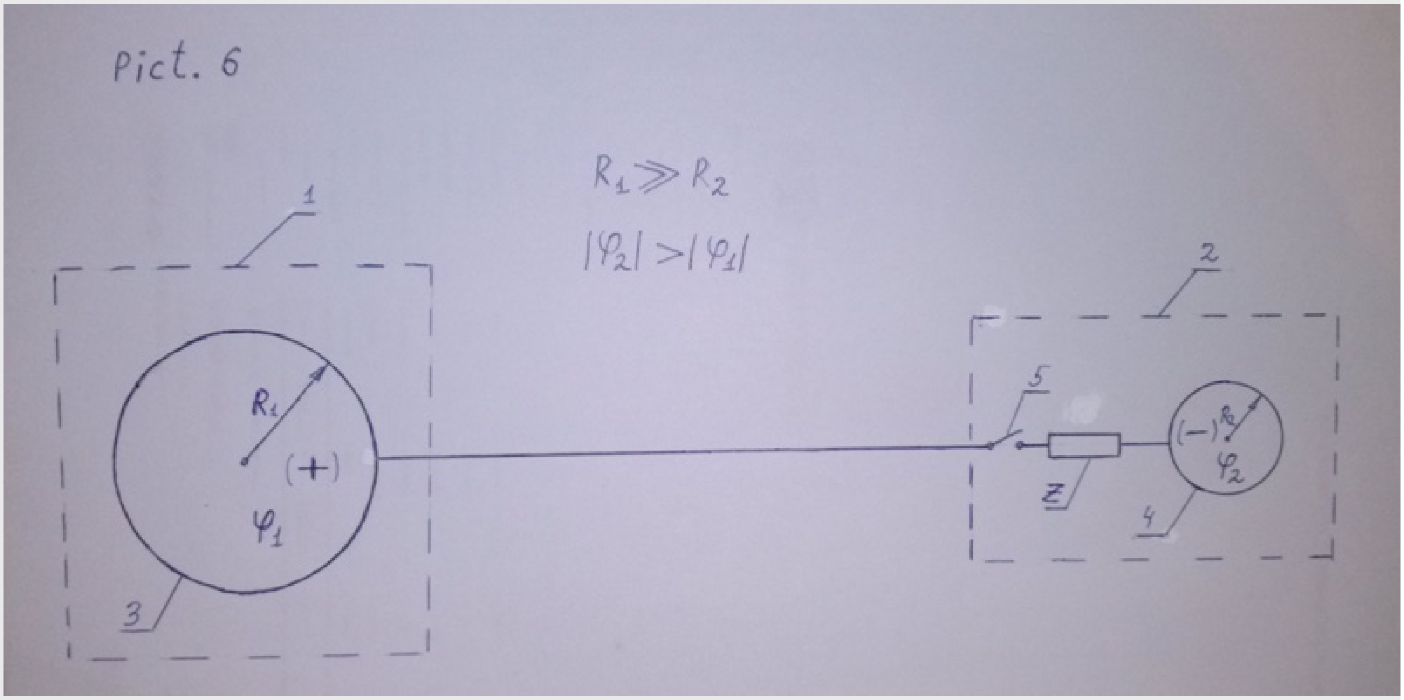
Besides, there is one more option - to apply "the third way of an electricity transmission", though it and more difficult for technical realization in devices, than the first two.

CHAPTER 5. A THIRD WAY OF A SINGLE-WIRE ELECTRICITY TRANSMISSION.

The idea is that for small (comfortable) geometric dimensions of the store of the receiver it would be placed at the half of period a large number of charges, much bigger, than it can place at safe potential on the line. And, potentials on object can be and much more, than on the line. It is admissible from the point of view of safety measures. As the small device of the receiver can be insulated carefully is a small space. But all of a transmission line is very difficult and in some applications as it was stated above, it just also has to be without isolation. This large amount of the charges will be "pumped" through the load toward the transmission line carrying the charges with opposite sign, and despite the fact that we have to expend energy in the beginning (to charge the receiver store) the total received by the load energy will be more than in the first two methods.

We will define this way so - giving of charges to object at safe potential on the line to the object stores, which are previously charged to higher potential, through the loads (which are on object), and charges on stores have to be an opposite sign, in relation to transferred.

This method has been presented long time ago in [1], but was then not well explained.In order to understand how it works, let's solve the small problem in physics, it is shown in Fig.6.



TERMS AND CONDITIONS:

In the transmitter (1) there is a electrically conductive sphere (3) very big sizes which radius we will designate (R1). On it there are many electric charges, and it is loaded to the potential (Phi1). It is small potential and it isn't deadly to a human body. Further, the transmitter is connected by one conductor with the receiver (2) in which too there is a electrically conductive sphere (4), but already very modest sizes convenient, say, for the moving object of a current supply. It via the switch (5) and through load (Z) is connected with the line. Radius of this sphere we will designate (R2). We can write that the radius (R1) is much more (R2). The switch is meanwhile opened. The sphere of the receiver is previously loaded to the potential (Phi2). And this potential is very high much more on the module, than the potential (Phi1). I think that makes sense to load this sphere (4) by means of an electrostatic machine*. Charges on a sphere of the receiver (4) are opposite on a sign to charges of a sphere of the transmitter (3). Previously having loaded a sphere of the receiver (4) we spent energy (Wzero). Now we close the switch (5). What will occur? The author believes that all charges from a sphere (4) through load (Z) will flow on a transmission line on a sphere (3). And, potential on a sphere (3) and on the line will practically not change as a sphere big and has many charges. After all condenser potential, as we know, is defined by a formula:
(5.1) Phi = Q / C ,
where Q - amount of charge, and C - capacitance.
Since we chose sphere large geometric dimensions (large R), it has a large capacity (because C = 4 x Pi x epsilon x epsilon zero x R) and has a large number of charges. Therefore, a small increase or decrease of the charge, which is necessary for the "work" with the sphere (4) will not greatly affect the potential of the sphere (3) and, consequently, the line. So it will have a real transmitter, as the annihilation of the charges that are currently on the line by entering the line of charges of opposite sign, all the time is offset by applying to the line charges from the generator. Then, part of the charges from the sphere (3), again, through a transmission line and through the load (Z) will flow to the sphere (4) to establish an equipotential surface. Ie until the potential on the sphere (4) will not be equal to the potential on the sphere (3) and on the line. The potential on the sphere (3) and on the line as before - will not change. Despite the fact that I am talking here about the two stages of the process, in fact, in terms of movement of electrons - it is continuous, and the electrons will flow in one direction only. It's just a matter of determining the sign of the charge. Time we take a half of the period and it more than enough for the described process. On load (Z), as a result of electron flow through it , some energy will be emitted **. We will designate it (Wz).

QUESTION N1: Will the released energy to the load (Wz) more than originally consumed at a charge storage facility (Wzero)? And if so, how much? The energy difference is denoted (deltaW).

QUESTON N2: To find (W3)- it is the energy received by object for a half of cycle at such way of an electricity transmission minus originally spent (Wzero), and to correlate it to the energy received for the same time at the second way of an electricity transmission (W2) (it more powerful, than the first way) on the store of the same size (R2), i.e. the same capacity (C2), and with the same potential on the line (Phi1). It all the same what to speak about comparison of power.

AUTHORS` SOLUTION:

The calculation given below, is very similar to the calculation of power for the second way of an electricity transmission given in Ch.2.

Work (A) of movement charges (Q) in electric field is defined by a formula:

(5.2) A = Q x deltaPhi ,

where deltaPhi - a potential difference of the sphere (4) and the line. At the beginning on the line and on a sphere (4) potentials of the different sign Phi1 and Phi2. Potential difference

deltaPhi = Phi1-(-Phi2) =Phi1 + Phi2.

But, in process of leakage of charges from a sphere (4) and their passing through the load (Z), potential on a sphere (Phi2) changes, therefore deltaPhi is function of quantity of charges on a sphere (4). We will write down it so:

deltaPhi = F(Q)

From the point of view of power, process of passing of electrons through the load can be divided into two stages. The first stage where work (A1) will be made - this movement of all charges from the receiver sphere (4) (we will assume negative charges) through the load (Z) to a power line. This process lead to a total disappearance of charges of this sign on the sphere (4) and, according to it, transformation of its potential into the zero. The second stage where work (A2) - this passing through the load of charges from the line will be made (in our example positive) to the receiver sphere (4) before establishment of potential on it (positive) equal to the potential on the line (Phi1). Thus, the general work or energy (that in this case the same) which is obtained for a half of the period on the load:

(5.3) Wz = A1 + A2

Let's try to calculate the work A1.

Elementary work (its differential) will be equal to the multiplication of the potential difference deltaPhi on the elementary charge (differential Q).

(5.4) dA1 = deltaPhi (Q) x dQ = F(Q) x dQ

As already mentioned above, the potential difference is a function of the charge on the sphere F(Q). Let's see how this function can be expressed. With the leakage of charges through the load, it decreases. The potential of the store (Phi2) is determined by the following formula.

(5.5) Phi2 = Q / C, then

(5.6) F(Q) = Phi1 - (-Phi2) = Phi1 + Phi2 =Phi1 + Q / C

Substituting this expression into (5.4), we obtain:

(5.7) dA1 = (Phi1 + Q / C) x dQ

In order to define work A1, we have to take the integral of the expression within the following limits: lower = 0, and the top, equal to the maximum (initial) charge that is Qmax = C2 x Phi2.

After the corresponding calculations which are excessive for bringing here, we will receive:

(5.8) A1 = Phi1 x Phi2 x C2 + Phi2 square x C2 / 2

Now let's calculate the A2.

Work or energy of movement of charges, as well as for A1, is determined by a formula (5.2). The potential difference between the line and the receiver sphere (deltaPhi) is also a function of the charge on this sphere. Let's see how in this case is defined F (Q). During all process, including at its beginning, potential on the line = Phi1. Phi2 sphere (4) potential is equal in the beginning 0, but in process of receipt on it charges which pass a way from the line through the load, potential grows. Phi2 is defined by a formula (5.5). Its final value will be Phi1. For a potential difference or F(Q) the following formula has to be fair.

(5.9) F(Q) = Phi1 - Phi2 = Phi1 - Q/C

Elementary work (dA2) is defined by a formula (5.4). We will substitute in it the expression which is just received by us for a potential difference, i.e. a formula (5.9). We will receive:

(5.10) dA2 = (Phi1 - Q/C) x dQ

In order to define work A2, we have to take the integral of the expression within the following limits: lower = 0, and the top, equal to the maximum (final) charge that is Qmax = C2 x Phi1.

After the corresponding calculations which are excessive for bringing here, we will receive:

(5.11) A2 = Phi1 square x C2 - Phi1 square x C2 / 2 = Phi1 square x C2 / 2

To find the general work or energy emitted on loading for a half of the period of an electricity transmission (Wz) we substitute A1 and A2 values in a formula (5.3). We will receive:

(5.12) Wz = Phi1 x Phi2 x C2 + Phi2 square x C2 / 2 + Phi1 square x C2 /2

Now we will try to find the answer to the question N1

According to the formula of calculating the energy of the charged capacitor determine Wzero:

(5.13) Wzero = Phi2 square x C2/2

(5.14) deltaW = Wz - Wzero

We will substitute in a formula (5.14) expressions for Wz and for Wzero, we will receive:

(5.15) deltaW = Phi1 x Phi2 x C2 + Phi1 square x C2 / 2

Thus, we see that we won power, and quite significantly, because the potential Phi2 can be very high, since the compact means of generating (eg electrostatic machines ***) - are available, and the means of isolation**** -the same.

LET'S ANSWER THE QUESTION N2.

We will consider energy which will receive object of a current supply in our task (at the third way of an electricity transmission) for a half of the period of an electricity transmission. We designated it as W3 above. We already found one component of W3 - it is deltaW - the energy emitted on load minus originally spent energy on store charging. Besides, the receiver store, having received a charge from the line of transfers (at the end of process) and therefore having got the potential Phi1, receives some power status, i.e. potential energy Wp which we too have to consider at calculation of a total energy W3 received by the receiver. Later, by consideration of a question of providing a continuity of an electricity transmission at the third way, it will be explained how to use this energy. So,

(5.16) W3 = deltaW + Wp

We will find Wp on a formula of calculation of energy of the charged condenser:

(5.17) Wp = Phi1 square x C2 / 2

We will substitute the found expressions for deltaW and for Wp in a formula (5.16). We will receive:

(5.18) W3 = Phi1 x Phi2 x C2 + Phi1 square x C2 / 2 + Phi1 square x C2 / 2 and after transformation:

(5.18) W3 = Phi1 x Phi2 x C2 + Phi1 square x C2

We will compare this expression to the energy received by the receiver at the second way of an electricity transmission for a half of the period - W2. The formula for W2 we learn in Chapter.2 It is a formula - (2.21). Phi in it it is possible to replace with Phi1, and C with C2. So: (2.21) W2 = 2 x Phi1 square x C2

In order to compare the energy W3 and W2, introduce the measure - n. This value shows how many times the potential of previously charged receiver store - Phi2 is more than a potential on the line - Phi1. We can write:

(5.19) Phi2 = n x Phi1

We will substitute Phi2 with the found now expression for Phi2 in a formula (5.18). We will receive:

(5.20) W3 = n x Phi1 square x C2 + Phi1 square x C2

and after transformation:

(5.20) W3 = (n+1) x Phi1 square x C2

Now you can see what will be equal to the ratio of W3 and W2?

(5.21) W3/W2 = [(n+1) x Phi1 square x C2] / [2 x Phi1 square x C2]

and after reduction:

(5.21) W3 / W2 = (n+1) / 2

ANSWER TO A QUESTION N1:
deltaW = Phi1 x Phi2 x C2 + Phi1 square x C2 / 2

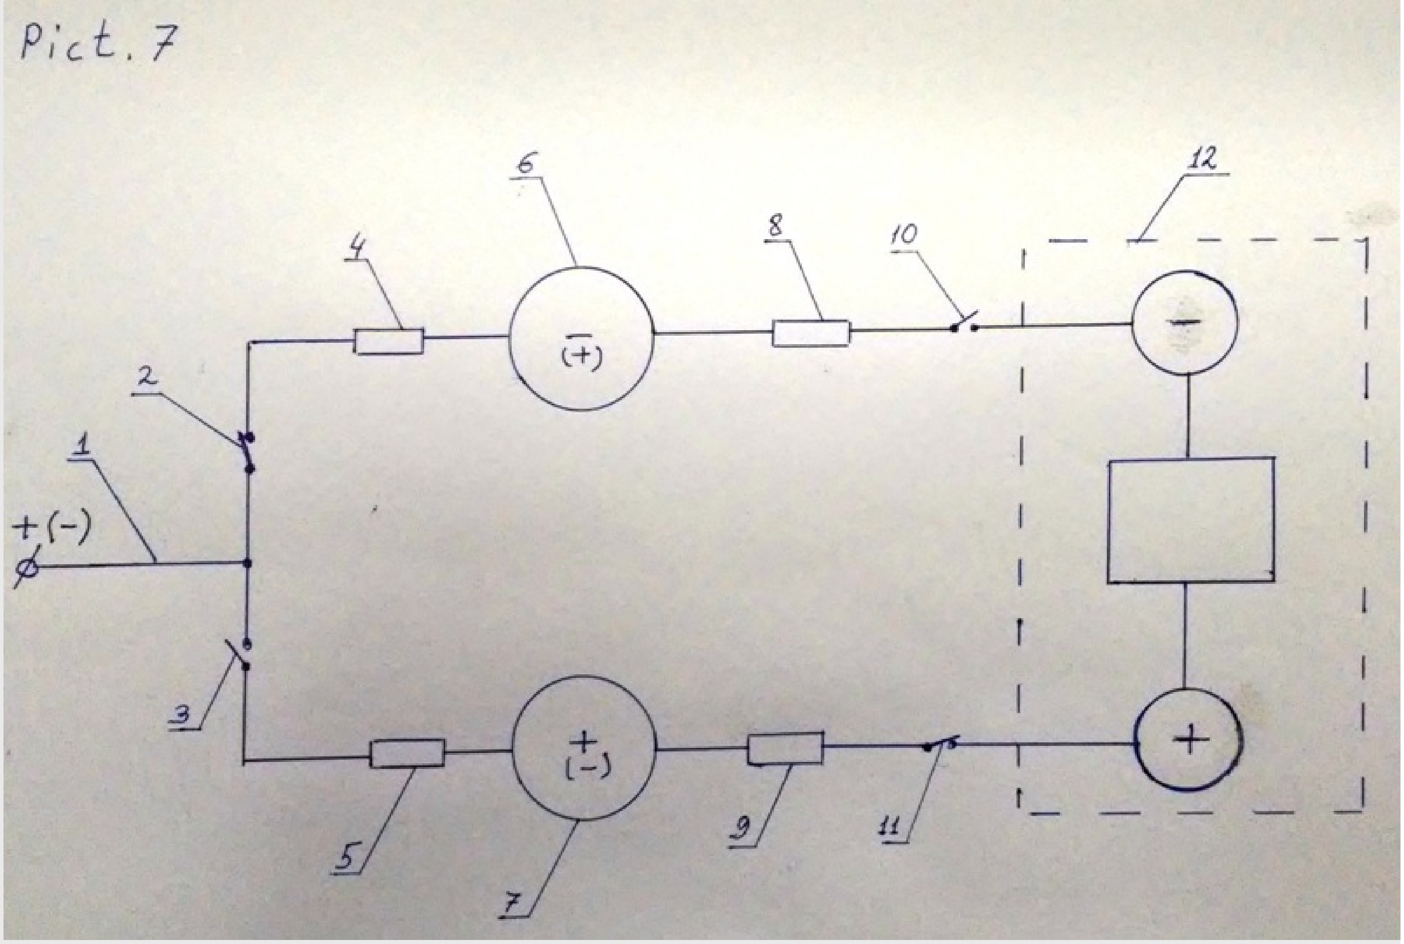
ANSWER TO A QUESTION N2:
W3 / W2 = (n+1) / 2 ,
where n = Phi2 / Phi1

CONCLUSION :

At the third way of single-wire transfer, the power received by the receiver will increase almost in one thousand times in comparison with the first two ways. So, if to take the potential produced by electrostatic machine of Vimshurst = 300 kV - it there will be Phi2 and potential on the line = 200 V - it will be Phi1 (potential, safe for human life, on the standard canons), n will be 1.5 x 1000, and W3 relation to W2 on a formula (5.21) will be equal about 750. But Vimshurst's electrostatic machine - it yet not a limit of perfection. Such task - to create the electrostatic machine developing the maximum voltage at the minimum sizes wasn't set for mankind simply yet. So, in ONE THOUSAND TIMES it is quite possible to reach increase in power.

PROVIDING CONTINUITY OF THE ELECTRICITY TRANSMISSION.

Pict. 7



The diagram (Pict. 7) displays only the object of current supply and appropriate to it single-wire transmission line segment (1).The transmitter remains same what it was at the first and second ways of an electricity transmission (see Pict. 1-5).

In this scheme it is impossible to put a two diode switch 'diode fork' on an entrance of the object of a current supply as at the first way (see Pict. 4). Because of the fact, that previously charged object stores (6 and 7) will electrically connect with each other. However, through loads (4 and 5), but so they won't save up charges, and will lose the potentials, and to us, at this way of transmission, it is necessary that they had many charges at high potentials. Therefore we will use the operated switches (2 and 3).

Loads (8 and 9) between terminals of the electrostatic machine (12) and stores of object (6 and 7) are necessary for purpose to use the energy Wp formed as a result of a charge of stores by charges of an opposite sign (in relation to output terminals of the electrostatic machine) at the end of time of connection of each of them to a power line. This energy will be used when the store is switched-off from a transmission line and connected for charging to the electrostatic machine by means of the operated switch (10 or 11).

What happens in the first period of the power supply we have already discussed in detail above in the solution of the task (see. also Fig. 6).

For providing a continuous electricity transmission, on object of a current supply (see Fig. 7) there is a second store (the best form - sphere) which is previously charged with electric charges of other sign, than the first, and in the second half of the period we switch a transmission line to it through other load (4 or 5). And on the transmission line itself already the charge sign too will be changed, because of connection of other sphere of the transmitter (or operation of the generator). And in this half-cycle too everything will occur as in the considered task. In that part of the period when any store of object is switched-off from the line, it will be loaded on the object with the help, we will tell, the electrostatic machine or other device, but in the beginning of this half-cycle it will give the charge, which remained from the previous half-cycle, through the corresponding load (8 or 9) connecting it to the charger. Thus the power status received from the line of transfers at the previous half-cycle (Wp) will be used through this load.

If to compare this process to charging of the neutral store, yes, it is valid, the part of charges going from the electrostatic machine, equal to "spaciousness" of the store of the receiver Q = C x Phi at the potential of line = Phi1 will be annihilated, and must be "restored" by electrostatic machine. This of course would require additional energy (compared to charging a neutral store) from the electrostatic machine, but it will be "returned to us"(the truth with small losses which we don't consider in this calculation) i.e. will turn in "useful" as it will be allocated on load, and from loads we take energy for return to the electrostatic machine and on performing of useful work.

Algorithm of operation of the switches operated (naturally automatically) the following: in the first half-cycle switches (2) and (11) are closed, and opened (3) and (10). And in the second - are closed (3) and (10), and are opened (2) and (11). In the third half-cycle - as in the first, and in the fourth - as in the second etc.

When selecting receiver stores shells material at the third way, it is necessary to pay attention not only to dielectric permeability of material, as at the first two, but also to its electric durability as we will deal with high and life-threatening voltage. Besides, it is necessary to look how these properties of material will behave with the planned electricity transmission frequency (it concerns also the first two ways). Cost too should be considered.

ELECTRO-RECEIVER OF OBJECT OF A ELECTRIC POWER SUPPLY, WORKING AT THE THIRD WAY OF ELECTRICITY TRANSMISSION.

TRANSFER OF THE ELECTRIC POWER ON OBJECT IN THE PRESENCE OF A SIMILAR COLLECTOR IS CARRIED OUT AS FOLLOWERS.

The generator (G) delivers on a power line charges of a different sign, in each half-cycle different, in one half-cycle - plus, in others-minus. And as he is connected by one terminal to the buffer store (in this example it is Earth - the grounding displayed on the scheme), these charges are "free", i.e. capable to fill a surface of conductors. You can object to this term, but how then to distinguish charges that could put a battery or generator in an electrical circuit connecting the two their terminals from the charges that capable to fill surface of free conductors and to interact with the same "free" charges? In any battery or generator "outside forces" divide charges. But from a terminal of the ordinary battery or the generator they are able to flow only on other terminal of the same device. Even to the terminal of other battery with an opposite sign they won't begin to flow. And in the Earth they won't begin to flow just like that (with an empty second terminal). Otherwise the situation is with the source given in the scheme and with electrostatic machines in which "outside forces" work too. It turns out that presence of "outside forces" for development of "free charges" - the necessary condition, but insufficient as mathematics say.

On a current collector 1 to which lead a line there is a Unit 3. A purpose of this unit - to define what charges in this half-cycle are on the line (plus or minus). If the unit is connected to the line, then it with it is helped by the device switch 4 (the device 4 is given as an example, also other options, say, the device consisting of diodes, electroscopes and optical sensors are actually possible - petals of electroscopes will cross beams), which operation we will consider later. But it can not be connected, then the sign of charges is defined by means of Clock 5 which are synchronized with the generator. The second purpose of the Unit 3 is development and a message of the operating signals on the operated switches (S1, S2, S3, S4). Passing of the operating signals on the scheme is conditionally designated by a stream 17 (the shaded arrows). These signals will depend on what charges (on a sign) in this half-cycle on the line of an electric supply.

On a current collector 1 are the electrostatic machine 15 and its stores of charges (10, 11) with the isolating covers (for safety) (12,13), the accumulator 14, the DC motor (M) for rotating the disk of electrostatic machine. All this "housekeeping" is necessary to receive more 'free' charges from the power line which is under the low potential, safe for life. The motor takes the electric power from the accumulator, puts the electrostatic machine in action and that charges the stores, one (we will tell 10) with positive charges, and another (we will tell 11) negative. This process goes constantly to all the time of an electricity transmission, irrespective of the fact which in this half-cycle charges (positive or negative) on the line going to a current collector. It is thought that the energy received on loads (Z1, Z2, Z3, Z4) quite will be enough both for recharge of the accumulator and for providing consumers of energy 2 objects. Streams of energy 16 are designated on the scheme by not shaded arrows.

The basic working elements of a current collector are stores of charges (6 and 7) and above-mentioned loads (Z1, Z2, Z3, Z4). Stores are surrounded with covers (8 and 9). These covers have double function: to increase the storage capacitor capabilities of stores, dielectrics of which they consist if surround the conductor, then with success it is done, and to isolate stores for safety reasons as on stores there will be sometimes a high voltage. By the way, the case of all current collector has to be made of the good insulating stuff capable to protect the person from high voltage.

We will notice that at the beginning of any half-cycle one of stores of object (6 or 7) has to be completely charged from the store of the electrostatic machine (10 or 11) and have the high potential, equal with him, and another has to begin to be loaded from other store through one of the loads (Z3 or Z4).

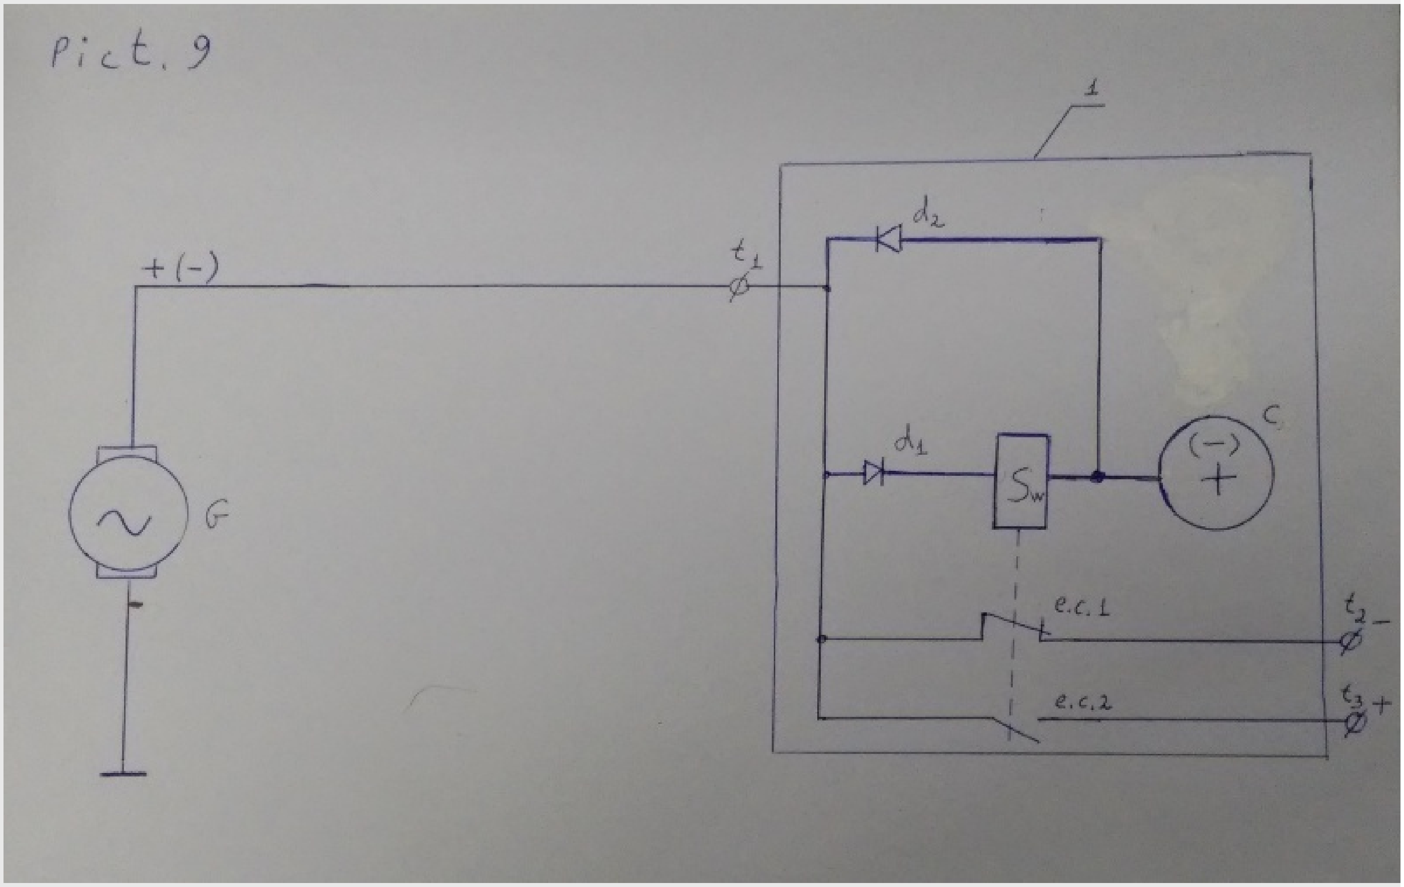
We will consider a "negative" half-cycle in the beginning. On the line the negative charge, the store 6 is loaded positively to the potential of the electrostatic machine (it 'inheritance' of the previous "positive" half-cycle), the S1 switch is open, the S3 switch is closed, the S2 switch is closed, the S4 switch is open. What is going on? The store 6 and the line interact through Z1 load, this process has been described above, on load energy is emitted, she is shown by not shaded arrow departing from her. Energy goes to the consumer of energy 2 objects and for accumulator charging 14. At the end of this half-cycle, the store 6 will get a negative charge and potential of the line and will transfer this "inheritance" to following, already "positive", half-cycle of an electricity transmission . The store 7 in the same time interacts with the store of the electrostatic machine 11 through S4 load. On the store 7 a positive charge and potential of the line (which has got to it "in inheritance" from the previous "positive" half-cycle) and at the end of this "negative" half-cycle it will be charged from the store 11 negatively and will get the potential of the electrostatic machine. From load Z4 energy will go to the same purposes.

Now, on the line "comes" the "positive" half-cycle. The Unit 3 "feels" it and "sends telegrams" on the shaded arrows on the operated switches. As a result S1 and S4 are closed, and S2 and S3 - open. The store 7, having high negative potential from last half-cycle, interacts with the line through Z2 load, at the end of a half-cycle he will get a positive charge and potential of the line. And the store 6, having a negative charge and potential of the line, interacts with the "positive" store 10 of the electrostatic machine through Z3 load. At the end of this half-cycle he will get the high positive potential equal to him.

When on the line again "come" "negative" half-cycle, object stores again, will have, the "inheritance", described right at the beginning. And the Unit 3, "having understood a situation", will open S1 and S4 and will close S2 and S3.

And so on everything will cyclically occur.

SWITCH *****,OPERATING DEPENDING ON A SIGN OF CHARGES ON A POWER LINE.



Pict. 9. THE SWITCH *****, ACTING IN ACCORDANCE WITH THE SIGN OF THE CHARGES ON THE POWER LINE.

This switch - unit 4 from the previous diagram (Figure 8).

1- the housing.

Sw- relay.

C-store of charges.

e.c.1- normally closed contact.

e.c.2- normally open contact.

Operation of this device is as follows.

As already mentioned above, the apparatus 4, part of unit 3 (scheme 8) should provide recognition charge sign which currently are in the single-wire transmission line as well as production and send control signals to the switches (S1, S2, S3, S4). Charges from a transmission line enter on the t1 plug. After it they are waited by the diode fork of d2 - d1. If positive charges, they, seeking to fill the store C, pass through the d2 diode and a winding of the Sw relay, having turned on this relay. If charges on the line the negative, then positive charges from the store C via the d1 diode go to the line (and are annihilated with the negative charges of the line) and pass a Sw relay winding. The Sw relay in this half-cycle will be in a silent state - there is no current through a winding.

Thus, depending on the operation or non-operation switch Sw charges recognition occurs on the line.

So:

When "+" charges on power line running to the object, the relay Sw is triggered (current passes through its winding) closes its contact e.s.2 that supplies currents (control signals) to the relay coil switches S2 and the S3, and, thus opens them. Normally closed contact e.s.1 thus opens and stops the currents flow (control signals) via a relay coil S1 and S4 and thus disables them.

If '-' charges on the transmission line, the relay Sw is de-energized , contact e.s.1 closed. He sends control currents to the relay S1 and S4 switches and opens them. e.c.2 - open. He stops for the currents in the windings of relay controlled switches S2 and S3, and disables them.

e.c.2- normally open contact.

FORMULA FOR POWER AT THE THIRD WAY OF THE SINGLE - WIRE ELECTRICITY TRANSMISSION.

Let's consider energy which will be received by object of an electric power supply at the third way of an electricity transmission for a half of the period of an electricity transmission. We already found it above and wrote for it a formula (5.18) having designated as W3.

(5.18) W3 = Phi1 x Phi2 x C2 + Phi1 square x C2

Now for larger simplicity and clarity we will change designations and we will explain them. W3 is replaceable on A, Phi1 to Phil, Phi2 to Phim. C2 can be replaced just with the simple C.

Let's rewrite taking into account new designations a formula (5.18), now it will become a formula (5.22).

(5.22) A = Phil x Phim x C + Phil square x C,

or

(5.22) A = C x (Phil x Phim x C + Phil square),

or

(5.22) A = C x Phil x (Phim + Phil)

Here :

A - the energy transferred to the object for half frequency period.
C - the capacity of one of receiver stores (there are two identical stores).
Phil - potential on a transmission line (its absolute value).
Phim - the potential of an electrostatic machine or some other device , which charges receiver stores (also its absolute value).

To find the power (denoted by P3), it is necessary to divide the work (A) on the time for which we have found it . We shall take an interval of time (t) equal to a half-cycle (t=T/2) of the frequency (nu) of switchings of the direction of a current of charges in case of a single-wire electricity transmission. Write a formula.

(5.23) P3 = A / t = A / (T / 2), but the T = 1 / nu, so, finally, this formula is as follows:

(5.23) P3 = 2 x nu x A

Substitute in this formula the expression for A (formula 5.22). We get: (5.24) P3 = 2 x nu x C x Phil x (Phim + Phil).

Now let's express storage capacity through the other parameters, as we did for the counting capacity of the first and second methods in the Chapter 2.

(5.25) C = K1 x f (d, epsilon) x R

Where:

K1 - coefficient , approximately equal (as not all stores of receivers will be the correct spherical form) 4 x Pi x epsilon zero. K1 is approximately equal = 1.11 x 10 to the minus tenth degree.
f - function, with parameters: d - receiver store cover thickness, an epsilon - dielectric permeability of material of which the cover is made. f > 1.
R- is the radius of the store

Substituting this formula in the expression for power. We get:

(5.26) P3 = 2 x K1 x f (d, epsilon) x nu x R x Phil x (Phim + Phil).

We will compare this formula to the formula derived by us in Chapter 2 for the power transferred in case of the second method of an electricity transmission (formula 2.24).

(2.24) P2 = K2 x f (d, epsilon) x nu x R x Fi square,

where Fi is a potential on the line, i.e. it is Phil in the present designations, and K2 = 4 x K1

We can rewrite a formula (2.24) in the following look now

(2.24) P2 = 4 x K1 x f (d, epsilon) x nu x R x Phil x Phil

and to compare it to a formula (5.26). We see that in a formula for the third method, one of multiplicands (Phil) is replaced on (Phim + Phil). And as Phim is a potential of the electrostatic machine, and it much above Phil, so delivered power for the third method will be much higher.

There is a question why in the case of count of power for the second method of an electricity transmission we didn't consider the potential energy Wp received by the store at the end of a half-cycle? But for the third - consider? - Because, this potential energy, we "transfer" without using in the following half-cycle (only on the next time span it brought benefit)- second way. And here (third way) we its, truth, transfer too without using in the present half-cycle, but we receive it (not its, it is more correct correct to say - equal to it) on the other store in the same interval of time, i.e. in a "estimated" half-cycle. Energy is received in the beginning of charging from the electrostatic machine of the parallel store on the appropriate load (Z3 or Z4 - see the Diagram 8).

We will remind that calculation is made for low frequencies of an electricity transmission. For high there will be differences. The main is that the geometrical sizes of stores of the receiver will cease to influence the accepted power as these conductive bodies won't manage to be filled for a half-cycle with charges. It is confirmed in work[10

NOTES :

* The author has an idea how to make an electrostatic machine with a miniature mechanism, i.e. does not take up much space on the receiver of the object, and without rubbing brushes - collectors. In fact, this idea belongs Kirsanov B.P., but the author of this article it creatively developed and perfected.

** The load, as noted in Chapter 1, should be in the form of a winding motor or transformer because of the three manifestations of the electric current (electromagnetic, thermal, chemical) with single-wire electric power transmission guaranteed only one thing - electromagnetic.

*** Wimshurst electrostatic machine, for example, with relatively small size, gives us 300 kV.

**** So, for example, electric durability of mica =135 kV/mm, polyethylene makes 40 kV/mm, and ebonite and porcelain = 25 kV/mm. Therefore , the insulation thickness of only a few cm can protect from breakdown at voltages of above-stated electrostatic machine.

***** If we want to define a sign of the plug of the battery or other device which isn't (like a given above transmission line) a source of 'free' charges, it is necessary to connect the second plug of the battery to the 'buffer' store of charges, i.e. to the big conducting body or to the Earth.

По поводу заявки 355 9986/07 033494
от Института [redacted]

АКТ ИСПЫТАНИЯ УСТРОЙСТВА

Настоящий акт подтверждает, что в лаборатории №3 отдела №6 Института [redacted] I7 января I986г. было проведено испытание модели установки, которая была собрана по схеме, соответствующей описанию заявки на изобретение "Устройство для передачи электроэнергии" № 355 9986/07 033494.

В качестве источника питания использовалась стандартная промышленная электросеть /250В/. К изолированной установке шел только один проводник длиной 7м, сечением 0,8мм^2. В качестве накопителей зарядов использовались 4 картонные параллелепипеда /по два на каждый вид зарядов/, обмотанные металлической фольгой /размеры параллелепипедов 25x25x40см/. Коммутационные проводники были длиной приблизительно по Iм и сечением 0,8мм^2. Функцию электрических вентилей выполняли диоды марки Д247. Включенный последовательно с нагрузкой 5,IМОм микроамперметр марки М366 №I09III показывал ток около I0мкА.

Таким образом, возможность протекания тока через нагрузку /что ранее оспаривала экспертиза/ была доказана.

На испытаниях присутствовали:

Эксперты ВНИИГПЭ В.А.Круглова, К.И.Фотина

Translation :

CHAPTER 7. A SINGLE-WIRE POWER TRANSMISSION APPLICATIONS.

So we see that the ability to transmit electricity at one conductor to an isolated object, still weak, but still there. But there is a question, and for what purpose in general these should be engaged?

The author according to his fancy may suggest the following applications.

1. Power supply of the mobile objects contacting to the conductive firm surface / the liquid environment. It can be, for example, robots with the built-in intakes, and the floor of the machine hall will be carrying out. The single-wire electricity transmission won't be, unlike two-wire, to limit their mobility. Charging or change of accumulators won't be required. Still it can be vehicles on an electricity conductive roadbed. I will remind that I had long ago, in the USSR, article on this matter [1]. Now, when everywhere in big cities there are separate road strips for public transport, it can be real. It is only necessary to make these strips electricity conductive (for the person if only he isn't grounded" contact with such strip won't constitute big danger). It is optional to do conductive this strip on all width, for the maneuvers which aren't interrupting electricity contact of a slip ring will be in it a narrow strip enough. It is natural that these objects of a current transfer have to have the corresponding current collectors where as stores their conducting cases or part them can serve. In addition, for ensuring electric contact there have to be slip rings representing, for example, freely turning conducting castors. Water

crafts in the electrolytic environment, including salty water can also be mobile objects of a current transfer. We will imagine an artificial pond with the sea or added some salt water and with the electricity isolated bottom. On it the boats with electric motors possessing the corresponding current collectors [4] can move.

2. Information electricity transmission when it is difficult to ground or duplicate the line carrying current and information (providing the second conductor). Such situations are rare, but, nevertheless, sometimes, can meet. Then, having the corresponding equipment, by means of such electricity transmission we can transmit signals modulating its parameters. For example, it is possible to transfer information and even energy on the metal pipe which isn't contacting to the earth.

3. It is possible to try to use such way of transfer of the electric power and information on monorail roads.

4. Power supply zeppelin having conductive body (huge storage charges) by means of thin cables coming from the ground. The cable for each zeppelin will be only one. Also will be a thin wire, with the coaxial carrying-out cover intended for prevention of an exit outside of the electromagnetic radiation which can be harmful to all live and, besides, will create a radio noise. It is possible to imagine and the return electric energy when on the zeppelin solar batteries are installed on all its surface, and the cable transferring the developed energy to the earth there will be a single thin wire with a coaxial cover as such cable will be easier and won't pull the zeppelin strongly down, owing to that that the wire can be very thin at a single-wire electricity transmission.

5. Transfer of the electric power on such single-wire lines to the isolated objects will save metal of electricity cables, and not because a wire only one, after all single-wire lines, are already applied to the grounded objects, and because wires can be made thin owing to other mechanism of conductivity which hypothesis of action is given above in Chapter 1. However, as reception objects it will be necessary to build buildings of the big sizes with the electricity conductive cases which, however, can be used in economy, say, as warehouses. Wires, as it was noted above, it is necessary to envelope in the shielding cover. And, even despite it, in view of the small diameter of such coaxial cables, the economy of metal is possible.

6. Transfer of electric power / information on the conductor or the channel having gaps. It can be both the metal conductor, and the interrupting stream of electrolyte. About possibility of a single-wire electricity transmission on not continuous conductor it is possible to read in work [4]. Besides, it is confirmed by a series of experiments... in this work.

7. Transmission of electricity / information between two crafts / vehicles upon contact of their bodies. The shells must be conductive, but not over the entire surface, otherwise we will encounter the "Faraday cage" effect.

8. Single-wire transmission of electricity in the plasma channel formed in the air by means of a laser beam. For information, energy and military purposes.

9. For medicine. For diagnostic devices.

10. Disinfection conductive surfaces. Nikola Tesla discovered that high frequency currents and high voltages have a bactericidal effect. For some conductive surfaces, especially hard-moving and rotating, bactericidal transfer currents may be more convenient for just one conductor and not two.

ЭЛЕКТРОПРОВОДЯЩЕЕ ШОССЕ

СОЗДАНИЕ ЭКОЛОГИЧЕСКИ ЧИСТОГО, ДЕШЕВОГО И НАДЕЖНОГО ТРАНСПОРТА — ОДНА ИЗ ВАЖНЕЙШИХ ИНЖЕНЕРНЫХ ЗАДАЧ ВО ВСЕМ МИРЕ. МНОГИЕ УМЫ ЗАНЯТЫ СЕЙЧАС РАЗРАБОТКОЙ РАЦИОНАЛЬНЫХ КОНСТРУКЦИЙ ЭЛЕКТРОМОБИЛЕЙ. АВТОР СЧИТАЕТ, ЧТО ЭТИ ПОИСКИ ИДУТ НЕ ВСЕГДА В ТОМ НАПРАВЛЕНИИ, ГДЕ ДЕЙСТВИТЕЛЬНО МОЖНО БЫЛО БЫ ОЖИДАТЬ ПРИНЦИПИАЛЬНО НОВЫХ ВОЗМОЖНОСТЕЙ.

А. ИОФФЕ,
инженер

Трамвай экологически чист, но чересчур «прямолинеен», троллейбус чуть маневреннее, но начисто лишен инициативы — не может оторваться от проводов. Неисправность на линии и троллейбуса, и трамвая выводит из строя весь маршрут. Свободнее чувствует себя электромобиль, но ему приходится тащить в кузове громоздкие аккумуляторы, а это не что иное, как бесполезное превышение мощности; иными словами, низкий КПД. И на большой пробег по ненаселенке рассчитывать не приходится — без подзарядки аккумуляторов не обойтись.

Вот если бы удалось сделать дорожное полотно так, чтобы его верхний слой стал токопроводящим, а нижний был изоляционной прокладкой, тогда электромобиль получил бы основную часть энергии от электропроводящего шоссе, а аккумулятор (небольшой, конечно) оставался в резерве — вдруг придется свернуть с основной дороги. Токосъемник электромобиля легко выполнить в виде устройства, не ограничивающего маневренности машины.

Что это — досужие фантазии или реальность?

Я бы сказал, реальность, если появится возможность передавать электроэнергию по одному проводнику. Но об этом мы все слышали еще в школе. Удивительно, почему мне не приходилось читать о серьезном использовании эффекта, известного всем по школьным учебникам. Вспомните лабораторный опыт. Заряжаете, скажем, положительными зарядами шар из проводящего ток материала. Соединяете шар-носитель зарядов — одним проводником с незаряженным шаром. Часть зарядов перетекает с первого шара на второй. Заметьте, мы передали электрическую энергию изолированному объекту с помощью одного лишь проводника.

Разовьем эту идею. Пусть на изолированном объекте установили два шара-накопителя зарядов. Будем использовать проводник в периодическом режиме. В первый полупериод передаем по нему положительные заряды от положительно заряженных накопителей передатчика, а во второй — отрицательные. Накопители на объекте будут предназначены каждый для зарядов своего знака. Заряды с накопителей на объекте можно снимать через полезную нагрузку RH (см. рис. 1). В установке, изображенной на рис. 2, в качестве буферного накопителя, принимающего заряды, разделяемые генератором, может быть использована Земля или тело, обладающее большой собственной емкостью.

Вместе с Б. П. Кирсановым, сотрудником Физического института им. П. Н. Лебедева, мы хотели защитить идею этой установки авторским свидетельством на изобретение («Устройство для передачи электроэнергии», заявка № 3359506, 07 033494), но эксперты ВНИИГПЭ отрицали ее работоспособность, не поверили, что ток потечет через нагрузку (RH). Тогда мы собрали опытную установку, которая продемонстрировала появление тока в нагрузке. Составили акт испытания модели. Но эксперт, а затем и Контрольный совет ВНИИГПЭ отказали нам в авторском свидетельстве, сославшись на то, что мощность, передаваемая объекту, невелика, поэтому наша установка практической ценности не имеет. Но мы и не подавали заявку на новый мощный источник энергии, мы хотели лишь «застолбить» идею, и опытная установка доказала работоспособность этой идеи.

По расчетам, передаваемая объекту мощность растет вместе с частотой передачи зарядов разного знака, с увеличением емкости накопителей и потенциала, при котором происходит токопередача. Повысить передаваемую мощность можно, например, таким путем. Перед началом передачи тока на накопители подаются заряды под большим потенциалом. Это обеспечит совместная работа небольшой аккумуляторной батареи и устройства, повышающего напряжение (см. рис. 3).

В первый полупериод, когда на проводник от передатчика подаются заряды положительного знака, коммутационное устройство соединяет проводник с накопителем отрицательных зарядов. Ток течет через RH_2. Во второй полупериод, когда на проводнике отрицательные заряды, коммутационное устройство соединяет проводник с накопителем положительных зарядов, и ток течет через RH_1. Часть полезной мощности подадим на подзарядку аккумуляторной батареи, а другую часть используем для совершения полезной работы.

В установке такого рода высокие потенциалы заключены внутри токоприемного устройства, хорошо изолированного от пользователей. На проводнике, с которым контактируют люди, будут только небольшие неопасные (меньше 220 В) напряжения.

Итак, мы показали, что в принципе передача электроэнергии по одному проводнику возможна. Устройства для реализации этой идеи могут быть разные — широкий простор для изобретательской мысли.

Памятная с детства школьная физика — разрядник Герца и шары, заряжающиеся друг от друга.

CHAPTER I

THE IONISATION OF THE ATMOSPHERE

The electrical conductivity of the air, first established by Linss in the year 1887, plays an important part in all the phenomena included under the title Atmospheric Electricity. Since 1901, when Elster and Geitel and C. T. R. Wilson independently discovered that this conductivity is due to the presence of small carriers of positive and negative charge called ions, the nature and the origin of the ions have been the subject of many investigations. Two different paths have been followed, the one dealing with the number and the nature of the atmospheric ions, the other with the radiations producing them. The two paths converge on the problem of the ionisation-balance of the atmosphere, the manner in which an equilibrium is maintained between the rate of creation and the rate of disappearance of the ions. It is only of recent years that an answer to this problem has emerged.

1. The Atmospheric Ions, Small and Large. A gas molecule is ionised when some external agency supplies the energy necessary to remove an electron from it, whereupon the positively charged residue of the molecule and the ejected electron, both of which under ordinary pressures very soon attach themselves to one or more uncharged molecules, form what is called an ion-pair. Such ions are known as "normal", "small", or "fast", and when found in the atmosphere have mobilities of the same order as those determined for pure dry air in laboratory experiments, about 1·5 cm./sec. in a field of gradient 1 v./cm.

The presence in the air of minute particles of dust and salt, of the products of combustion, and of extremely small drops of water even when the air is unsaturated, leads very often to the capture of a normal ion by one of these condensation or Aitken nuclei, as they are termed, and so to the formation of another type of ion of low mobility,

CHRIST'S CO

ranging from 0·008 to 0·0003 cm./sec., known as "large", "slow", or "Langevin" ions. Roughly speaking, one-third of the condensation nuclei present in the air is electrically neutral, the other two-thirds carry, nearly equally, positive and negative charges captured from small ions. The interplay between the large and the small ions and the uncharged nuclei is of considerable importance.

Besides these two main types of atmospheric ion, a group of "intermediate" ions whose mobilities lie between 0·2 and 0·01 cm./sec. has been found to be present under special meteorological conditions such as low relative humidity. Some of these are known to be associated with molecular clusters of sulphuric acid from industrial processes.[1]

It has been found that the great majority of the ions, large and small, carry a single elementary charge, either positive or negative.[2] Over land areas the large ions considerably outnumber the small ones, often in the ratio of ten to one. Thus while the numbers, n_+ and n_-, of small ions of each sign per c.c. of the air over land usually range from 300 to 1000, those of the large ions, N_+ and N_-, amount to from 1000 to 80,000 per c.c. Since practically all the large ions are formed from the capture of small ones by nuclei, an increase in the number of these nuclei, such as is due to the fires of an industrial area, will increase the proportion of the large ions in the air at the expense of the small ions.

Over the oceans this state of affairs is reversed; the air away from land areas is but poorly supplied with nuclei and the large ions are in the minority. The mean values of n_+ and n_- at sea lie between 500 and 700 per c.c., while N_+ and N_- are about 200 per c.c. In view of their comparative freedom from capture by nuclei, it is at first sight rather surprising that the number of small ions per c.c. in mid-ocean differs little from the same quantity over the land, where the average values of n_+ and n_- are also about 600 per c.c. This is, however, to be explained (§ 12) by the fact that the decreased rate of disappearance

of the small ions over the sea is balanced by a decrease in the rate at which they are produced.

2. The Determination of the Number of Ions per c.c. To determine the numbers of the small ions, positive and negative, per c.c. (n_+ and n_-) an arrangement known as an Ebert ion-counter is usually employed. This consists in essentials of a long earthed metal tube A (Fig. 1) on the axis of which is mounted a charged insulated rod B, connected to a quartz fibre electroscope. Air is sucked through the tube for about five minutes by means of a clock-work driven fan F and the speed of the air-stream is arranged to be slow enough for all the small ions entering A with charges opposite in sign to that on the central rod to be drawn to B before reaching the bottom of the tube. The speed of flow must at the same time be great enough to make it impossible for any appreciable number of large ions to have time to reach the rod. If v is the volume of the air sucked through in the course of the measurement (indicated by an anemometer C registering its revolutions on a dial), the quantity of electricity gathered in by the central electroscope system is ven_-, where e is the elementary charge on a single ion and the rod

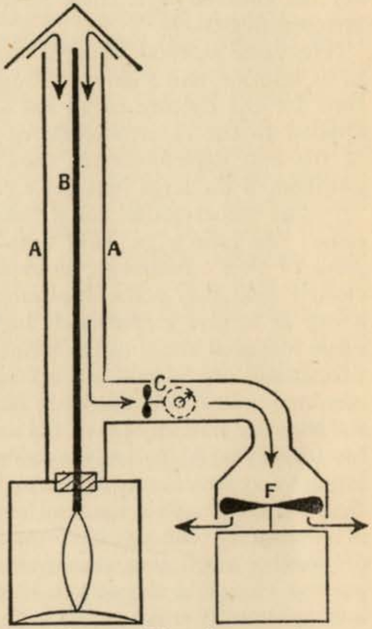

Fig. 1.—Ebert ion-counter.

is supposed to have been positively charged. If then C is the capacity of the whole central system, rod and electroscope, and V and V' are the potentials indicated by the electroscope before and after the experiment,

$$C(V - V') = ven_-,$$

an equation from which n_- can be found. To determine n_+, the measurement must be repeated with the rod B charged negatively.

The same method, using a longer tube, a stronger field in its interior, and a slower draught of air, and thus giving time for the capture of all the slow ions as well, can be applied to the determination of $N + n$. A combination of the two determinations then yields N_+ and N_-, the numbers of the large ions per c.c. of each sign.

The values found for n_+ and n_- are not usually the same; the ratio n_+/n_- over both land and sea has a mean value of 1·22. Although, as explained in § 22, the earth's electric field may sometimes affect the apparatus in such a way as to give a spuriously high ratio, Swann, who has made a special study of the point, concludes that when all precautions are taken a real excess of positive ions must be admitted. Probably the main factor causing this excess is the superior mobility (k) of the small negative ion; Nolan has found that k_-/k_+ has the value 1·16. A lower mobility implies a lower velocity of thermal agitation for the positive than for the negative ion, and consequently less likelihood of capture by condensation nuclei. This general excess of positive small ions does not necessarily involve a net positive charge in the air; it is easily compensated for by a comparatively small excess in the much larger number of large negative ions.

An instrument known as the Aitken dust-counter is often used to find the total number of nuclei, charged and uncharged, per c.c. It consists of a small expansion chamber filled with a sample of the air and saturated with water-vapour. The sudden movement of a piston gives an adiabatic expansion which causes drops of water to condense upon the nuclei; the resulting cloud falls upon a glass plate divided into squares and the number of droplets is counted under a microscope. Though called a dust-counter it does not record the coarser dust in the air.[3]

In a recent improvement on the Aitken counter (Nolan [3]) a much larger sample of saturated air is expanded in a cylindrical vessel. The opacity of the cloud then gives a relative measurement of the concentration of nuclei.

3. The Polar Conductivities and the Ionic Mobilities. A simple relation holds between the conductivity of the air and the numbers per c.c. and the mobilities of the ions responsible for conduction. Consider a point in the atmosphere at which the electric field intensity is F and the specific conductivity, the reciprocal of the specific resistance, is λ. The conduction current, i, through unit area drawn perpendicular to the field is then equal to $F\lambda$, for F is numerically equal to the potential difference, and $1/\lambda$ is the resistance, between the ends of a unit cube of the air. In this equation we assume that conditions are such that Ohm's Law can be applied to the air. Since the current is carried by positive and negative streams of ions moving in opposite directions we may write

$$i = F(\lambda_+ + \lambda_-), \quad . \quad . \quad . \quad (1.1)$$

where λ_+ and λ_- are called the polar conductivities.

Actually the existence of the two main types of ion, large and small, leads to the flow of four different ion-streams, two up and two down if the field is vertical, in each of which the velocity is different, being given by $F \times k$, where k is the corresponding mobility. The total current is thus

$$i = Fe(n_+k_+ + n_-k_- + N_+K_+ + N_-K_-), \qquad (1.2)$$

where k_+ and k_-, K_+ and K_-, are the mobilities of the positive and the negative ions, large and small respectively, and e is the elementary charge. From (1.1) and (1.2), if the oppositely moving streams are separated,

$$\lambda_+ = e(k_+n_+ + K_+N_+) \text{ and } \lambda_- = e(k_-n_- + K_-N_-). \quad (1.3)$$

In clear country air over land, n_+ and n_- number about 600 per c.c., while N_+ and N_- are about 2000 per c.c.;

k_+ and k_- are 1·5 approximately and K_+ and K_-, 0·0004. Here, therefore, the ratio of the first to the second term in each bracket above is 1100 : 1 and most of the conductivity of the air is due to the small ions. Near large towns, however, n is usually of the order of 100 per c.c. and N, on account of the heavy pollution of the atmosphere may be 50,000. Under these conditions the second term would be one-seventh of the first and the large ions would play a part in the transfer of electricity through the air.*

Nolan and Nolan have obtained the polar conductivities by separate measurement of the n's and k's in eqn. (1.3) above. It is, however, more usual to find λ directly, from measurements of the rate which the charge on an insulated body exposed to the free air is dissipated by the flow of ions to it. Consider a negatively charged body exposed to moving air and let σ be the density of the electrification on any portion of area dS. Positive ions will move to the body, and since the field F just outside the surface is $4\pi\sigma$, the current per unit area tending to dissipate the charge will be $F\lambda_+ = 4\pi\sigma\lambda_+$. The total dissipation current, obtained by integrating over the whole exposed surface, is $4\pi\lambda_+\iint \sigma dS$ or $4\pi\lambda_+ Q$, where Q is the charge exposed to the air. Since this current represents the rate at which the body losses charge, we have $-dQ/dt = 4\pi\lambda_+ Q$, a relation which provides a means of determining λ_+. A similar equation, with λ_- substituted for λ_+, holds for the case of a positively charged body.[4]

An arrangement used for this purpose is due to Gerdien (Fig. 2); it resembles the Ebert apparatus already described, but the air-stream is now made so rapid and the field in the interior of the tube so weak, that only a very small fraction of the total number of ions passing through A has time to reach the central rod. In this case the numbers of ions per c.c. are not appreciably altered by the experiment and Ohm's Law applies.

---

* The methods used to determine ionic mobilities are described in text-books on the conduction of electricity through gases.

If the potential V of the negatively charged central electroscope system is observed to rise at a rate dV/dt and if C is the total capacity of the central system, rod and electroscope, we have $-dQ/dt = -CdV/dt$. Also, if C' is the capacity of that portion of the central system exposed to the stream of air, the rod B and its support, $Q = C'V$, consequently

$$-CdV/dt = 4\pi\lambda_+ C'V, \quad . \quad . \quad (1.4)$$

a relation from which λ_+ can be determined. A similar experiment with the rod positively charged yields λ_-. The use made of the values found for the polar conductivities and an adaptation of the Gerdien method due to Schering are described in Chapter II, § 22.

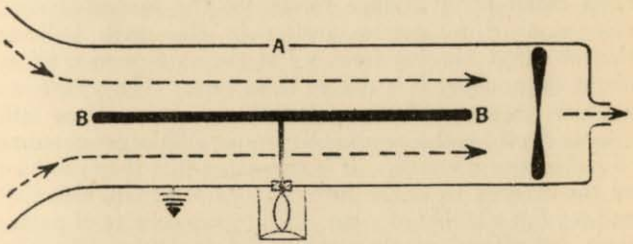

FIG. 2.—Gerdien conductivity apparatus.

4. The Ionising Agencies. Three principal agencies are responsible for the ionisation of the lower atmosphere: radiations from radioactive substances in the surface of the earth, radiations from radioactive matter present in the air itself, and the cosmic rays. For a discussion of their relative importance it is convenient to use the symbol q to represent the number of "pairs of ions produced per c.c. per second in air at N.T.P.", a quantity which will be referred to as the ionising power of the radiation. This phrase in inverted commas is usually represented by the symbol I. Thus the statement $q = 4I$ means that, at the point in question, the radiations create four pairs of ions per c.c. per second, if the medium there is air at N.T.P. The contributions of the three different agencies just mentioned to the total ionising power, q, are distinguished by the symbols q_e, q_a, and q_h.

5. The Effect of Radioactive Matter in the Earth. Uranium, thorium, and their products are widely distributed through the earth's crust, whose surface layers therefore emit α, β, and γ rays into the air. Since the α rays can emerge only from a very thin layer and can ionise only the first few cm. of the air, their effect is inconsiderable. The β rays can come from greater depths and penetrate much further into the atmosphere. Calculations based upon average values for the measured concentration of radioactive matter in the earth indicate that an effect ranging from 1 I at the surface to 0·1 I at about 10 m. above it is due to these rays. The γ rays are a more important factor, for they can come from still greater depths and consequently from a still larger quantity of radioactive material. It is estimated that they produce on the average 3 I at the surface, 1·5 I at 150 m. above it, and 0·3 I at a height of 1 km. The γ ray activity of potassium introduces another source of ionisation, for the potassium content of the earth's crust is considerable. No very detailed survey of this question has yet been made, but measurements indicate that the contribution of potassium may exceed that of the combined uranium-radium and thorium families. The average value for the ionising power of the earth-radiations near the ground has been found directly to lie between 2 and 10 I, which is in accord with the measurements of the radioactive content of the earth's crust. Local surface and geological conditions naturally have a marked effect upon the value of q_e at any given spot.

The radioactive content of sea-water is found to be very small in comparison with that of soil and rocks, and over the oceans the earth-radiation effect is negligible.

6. The Effect of Radioactive Matter in the Air. The atmosphere contains a considerable quantity of the radioactive emanations, radon and thoron, and their successive products. A wire charged negatively to a potential of a few hundred volts and exposed to the air

collects an easily detectable quantity of radium A and thorium A by recoil from the disintegration of these emanations. The gases themselves arise from the decay of radium and thorium within the earth, from which they escape by diffusion, by thermal convection, and as a result of decreases in the external atmospheric pressure. The greater portion of the ionisation thus produced is due to the α rays from the emanations themselves and from their A and C products, for here, unlike the case of the radiations from the earth, there is no absorbing layer between the disintegrating atom and the air. The radioactive gases and their products are fairly evenly distributed by atmospheric turbulence through the lower air. This "air-radiation" effect can be calculated from radioactive data if the emanation content of the air is determined. The emanations may be removed from a measured volume of air by drawing it through tubes cooled with liquid air or filled with coconut charcoal. The quantity of emanation condensed or absorbed is then determined by the effect produced in an ionisation electroscope, corrected for the decay of the material during the time of the experiment. A more direct method is to fill a closed ionisation chamber first with ordinary air and then with air which has been freed by the above method from the emanations and from their products, and to determine the saturation currents in the two cases. If these are i_1 and i_2 respectively, v the volume of the vessel and e the elementary charge, the value of the air-radiation ionising power, q_a, is given by $i_1 - i_2 = q_a ve$.

The results of such measurements agree with estimates based upon observations of the average emanation content of the air in placing the air-radiation effect at about 2 I in the neighbourhood of the earth's surface. Of this about 55 per cent. is due to radon and its products and the remainder to the thoron series. It varies somewhat with locality and with those meteorological conditions which determine the rate of escape of the emanations. Apart from the effect of strong upward winds in elevating the richer surface layers, the emanation content of the air should decrease fairly rapidly with height. Direct information on this point is difficult to obtain, but what exists indicates that the air-radiation effect falls to less than 2 per cent. of its surface value at a height of 5 km.

The effect, like that of the earth-radiation, is extremely small over the oceans, where the emanation content of the air is only about 1 per cent. of its value over land areas.

7. The Effect of the Cosmic Rays. The third factor in the ionisation of the atmosphere is a radiation of peculiar interest, whose origin and nature are still the subject of much investigation. It has a penetrating power which is considerably greater than that of the most penetrating γ rays from radioactive bodies, and it travels to the earth's surface in a downward direction, undergoing a certain amount of absorption on the way. Its ionising power at sea-level over both land and ocean areas when measured in closed metal vessels varies from about $2{\cdot}0\, I$ in low geomagnetic latitudes[6] to $1{\cdot}5\, I$ near the magnetic equator, the earth's field preventing the slower ionising particles from reaching the equatorial belt.

Until the year 1911 it was generally thought that the ionisation inside a closed vessel was entirely due to radiations from the walls and from radioactive matter in the earth and the outside air. It was therefore to be expected that this ionisation would decrease when the vessel was raised above the surface of the earth. This was tested in balloon ascents by Hess in 1911, and Kolhörster in 1913, who found that the diminution with height was appreciable only during the first kilometre, after which an increase occurred. These observations led Hess to postulate an ionising radiation coming from above and suffering partial absorption in the atmosphere.

The ionisation due to this "cosmic" radiation (so-called because it is now known to originate outside the atmosphere and to have little connection with the sun) increases rapidly with height above sea-level, rising tenfold in the first 5 km.

8. The Ionisation Inside a Closed Vessel. It is a matter of considerable difficulty to determine separately the ionising powers of the earth-radiation and of the cosmic rays. Calculations of the former must be based upon measurements of the radioactive content of the earth's crust, and these are necessarily tedious and rough. To proceed further, one must examine the ionisation produced in the air inside a sealed metal chamber under conditions which are modified from those existing in the free air by the presence of the metal walls. This involves correction to free-air conditions. A further disadvantage is that a new ionising agency is introduced, the radioactive matter in and on the inside walls. The ionising power of this "wall-effect", or the "residual ionisation" of the vessel as it is called, is a constant depending on the material of which the walls are made and the cleanliness of the inner surface. It is usually represented by the symbol q_0.

The total ionising power of all the radiations operating upon the gas in a closed vessel may be called q' and the modified effects of the three main ionising agencies q'_e, q'_a and q'_h; we then have

$$q' = q'_e + q'_a + q'_h + q_0. \qquad \cdot \quad \cdot (1.5)$$

We may suppose the vessel to take the form of a sealed ionisation chamber filled with air at N.T.P. which has been freed from radioactive matter. The saturation current carried by the ions to the central collecting electrode is then given by $i = q've$, where v is the volume of the vessel and e the elementary charge on an ion.

Various methods have been employed to separate out the four terms on the right-hand side of eqn. (1.5) from one another. The most satisfactory of these begins by determining q_0. The instrument is taken to a large snow-fed lake whose radioactive content, like that of the sea, is negligible. When it is sunk to the depth of a few feet in such a lake, the effects of earth and air-radiations are non-existent and eqn. (1.5) becomes $q' = q'_h + q_0$; on lowering the vessel still further, q'_h diminishes as the cosmic radiation becomes absorbed in the increasing thickness of water, and it is possible to reach depths at which the saturation current is practically constant and unaffected by further sinking of the instrument. At this stage $q' = q_0$, and the residual ionisation is determined. By combining this observation with that made close to the surface of the lake, q'_h may be found.

Since the effects of the cosmic radiation and of the walls of the vessel are both independent of local conditions other than height above sea-level, they remain the same when the instrument is transported to a site on land at the same level. A measurement of the saturation current in the chamber under land conditions gives q' as stated by eqn. (1.5), and hence the sum of the earth and air effects, q'_e and q'_a can be found. In actual practice the air-radiation effect within a closed vessel is extremely small; the walls exclude α and β rays coming from outside and reduce q'_a to the ionising power of the γ rays emitted by the B and C products of the radio-active emanations. This amounts to but 4 per cent. of the effect produced by the air-radiation in the free atmosphere, in the case of a vessel with steel walls a few millimetres thick. It is therefore sufficient to determine the air-radiation effect, q'_a, by calculation based upon a knowledge of the emanation content of the air and of the nature of the walls of the vessel. The fourth factor, the effect of the earth-radiation, q'_e, is then obtained by substitution in eqn. (1.5).

To pass from these closed vessel determinations of the effect of the radioactive matter in the earth to the effect to be expected in the free air, experiments may be made with screens of different thicknesses placed around the ionisation chamber and the values thus obtained for the earth-radiation effect extrapolated to zero thickness. In doing so account has to be taken of the effect of the screens upon q'_h.

To derive the true ionising effect of the cosmic rays in the free air from observations inside a closed vessel, account must be taken of the ionisation due to secondary radiation from the walls of the vessels. For a brass ionisation chamber with walls 2·5 mm. thick Hess has shown that the secondary effect is only 0·09 I.[6] It is therefore likely that the free-air value of q_h in temperate latitudes is not far from 1·90 I.

The greater part of the residual ionisation arises from α rays and takes place close to the walls; q_0 is therefore the effect of the residual ionisation near the walls divided by the volume of the vessel.

9. Summary of Ionising Powers of Various Agencies. The table on page 14 gives a rough idea of the effects of the three main factors in the ionisation of the air at sea-level, both in closed vessels of steel, a few millimetres thick, and in the free atmosphere. The values given refer to measurements at about a metre from the surface of the earth; they are averages and, except in the case of the cosmic radiation, are subject to considerable fluctuations with local conditions.

It is noteworthy that the rate of production of ions over land areas is about four times as great as over the oceans, where the ionisation is practically all due to the action of the cosmic rays. Over land and close to the surface of the earth, these rays are much less important, but at greater heights the effects of the earth and the air-radiations fall off rapidly as we have seen, so that from a height of one or two kilometres upwards, the cosmic radiation is the chief agent in making the air a conductor.

10. The Rate of Disappearance of the Small Ions. The number of ions produced by the agencies we have discussed will not increase indefinitely as time goes on. Even in pure filtered air, free from nuclei, the small ions disappear by diffusion to the walls and by recombination with one another. Experiments have shown that when the diffusion loss can be neglected, the equation $dn/dt = q - \alpha n^2$ applies to such filtered air, n being as before the number of positive or negative small ions per c.c., q the number of pairs of ions produced per c.c. per second, and α the so-called recombination constant of small ions. In the course of time a state of equilibrium will be reached, in which the processes of creation and disappearance of ions balance one another; then $dn/dt = 0$

and the equilibrium equation $q = \alpha n^2$ holds. Applying this equation to the free air, taking $q = 7{\cdot}4\, I$ from the preceding section and $\alpha = 1{\cdot}6 \times 10^{-6}$ cm.^{3}/sec. from laboratory experiments, we find $n = 2145$. This is very much larger than the number of small ions actually observed, which is round about 600 per c.c. The discrepancy is due to neglect of the important part played by the Aitken or condensation nuclei in capturing the small ions.

TABLE I

Ionising Powers at 1 m. above the Earth's Surface, Sea-level

Ionising Agent.	Ionising Power in Ion-pairs per c.c. per sec. in Air at N.T.P.			
	Unscreened Closed Vessel.		Free Air.	
	Over Land.	Over Sea.	Over Land.	Over Sea.
Radioactive matter in the earth . .	3·5	0	3·5	0
Radioactive matter in the air . . .	0·2	0	2·0	0
Cosmic Radiation .	2·0	2·0	1·9	1·9
	Total ionising power for the free air .		7·4	1·9

This question has been examined over many years, principally by Nolan and his co-workers in Dublin, and it is found to be extremely complex.[3] Separate considerations must be given to the capture of small ions by charged nuclei of opposite sign, which leads to neutralisation, and by uncharged nuclei, which leads to the formation of large ions.

For the small ions, making no distinction of sign, we write :

$$dn/dt = q - \alpha n^2 - \eta_0 n N_0 - \eta n N \qquad . \quad (1.6)$$

where N_0 and N are the numbers of uncharged and of oppositely charged nuclei per c.c. and η_0 and η are the coefficients for the two types of capture. For the large ions :

$$dN/dt = \eta_0 n N_0 - \eta n N \qquad . \quad . \quad (1.7)$$

disregarding the small loss by recombination of large ions with one another.

For equilibrium both dn/dt and dN/dt are zero, hence $\eta_0 N_0 = \eta N$ and

$$q - \alpha n^2 - 2\eta n N = 0 \qquad . \quad . \quad (1.8)$$

From experiment it is known that η is of the same order of magnitude as α and since $N \gg n$ as a rule, eqn. (1.8) reduces to

$$q = 2\eta n N = 2\eta_0 n N_0 \qquad . \quad . \quad . \quad (1.9)$$

If the total number of nuclei, charged and uncharged, is Z, so that $Z = N_0 + 2N$, eqn. (1.9) reduces to

$$q = \left\{\frac{2\eta_0\eta}{2\eta_0 + \eta}\right\} Zn \qquad . \quad . \quad (1.10)$$

This is of the same form as an equation given originally by von Schweidler, $q = \beta n$, though β is constant only if the concentration of nuclei, Z, is constant.[5] It states a linear law of recombination, as opposed to the quadratic law which holds for filtered air. If the action of the ionising agents could be removed, the small ions would disappear at a rate $dn/dt = \beta n$, and $n = n_0 e^{-\beta t}$ would be the number present at any subsequent time. The quantity $\theta = 1/\beta$ can, by analogy with the equation for radioactive decay, be termed the *average life* of a small ion. Eqn. (1.10) then becomes

$$q\theta = n \qquad . \quad . \quad . \quad (1.11)$$

in which θ should vary inversely as the concentration of nuclei in the air. Though this simple relation is only an approximation, it is useful for general purposes.

The average life θ is found over land areas to lie between 10 and 60 sec. according to the purity of the air, the higher values being associated with observations made in the country. Over the oceans it may be as much as 230 sec., according to the measurements of Hess[7] and of Mathias[8] on the island of Heligoland. The table below, taken from Hess, illustrates the great difference in the equilibrium between small and large ions brought about when the wind direction changes; the first set of observations was made when the wind blew from the nuclei-laden European mainland, the second when it blew from the polar regions:

TABLE II

OBSERVATIONS OF THE STATE OF ATMOSPHERIC IONISATION (HESS, HELIGOLAND)

Wind.	No. of Small Ions per c.c.(n).		No. of Large Ions per c.c.(N).		Total No. of Nuclei.	Average Life of Small Ion, secs.	
	n_+	n_-	N_+	N_-	$Z = N_0 + N_+ + N_-$	θ_+	θ_-
S.W. (Land)	220	267	1480	1510	6300	22	22
N.N.W. (Arctic)	794	843	200	200	1100	115	204

These authors find that for values of θ lying between 36 and 100 sec., Schweidler's linear eqn. (1.11) is valid; in purer air, where θ is greater than 100 sec., the simple equation no longer holds, for the quadratic recombination term αn^2 then becomes significant.

Measurements with city air have, however, shown that the sizes of the nuclei vary over a wide range and that the coefficients η_0 and η in eqns. (1.6) and (1.7) show a corresponding wide range of variation.[3]

When, as in a city, the air is continually being provided with fresh nuclei, they do not usually reach a final state of equilibrium with the small ions. This would require a time of the order of 15 min. and stable conditions such as are found only in mist and fog. A further complicating factor is the discovery that the meteorological conditions which cause large variations in the nature and the number of the nuclei also alter the value of q by altering the radioactive content of the air.

11. Methods of Determining the Average Life of a Small Ion. The average life, θ, of the small ions can be determined for a sample of air enclosed in an ionisation chamber by two methods suggested by Schweidler.[5] The first involves the separate measurement of the ionising power, q, of the ionising radiations, and of the number of small ions per c.c., n, and substitution in the equation $q\theta = n$. q is obtained from the saturation current, i, using the relation $i = qev$, where v is the volume of the vessel. The corrections to be applied have already been discussed (§ 8). The quantity n is found by allowing the air to stand undisturbed for a sufficient time for equilibrium between small ions and nuclei to be attained and then applying a strong field for a few seconds to sweep the small ions on to the collecting electrode. The second method involves the measurement of the currents flowing in an ionisation vessel for various values of the applied potential difference.[9]

12. The Ionisation-balance in the Lower Atmosphere. It is of considerable importance to decide to what extent the various factors in the creation and destruction of ions account for the state of ionisation actually observed in the air over land and sea. Any failure in this respect would suggest that new processes must be sought.

Although the variable nature of the process of capture by heavy nuclei prevents an accurate comparison of the rate of production of small ions with their rate of disappearance, the available evidence suggests that the chief factors in the ionisation-balance have been discovered. Over land areas where nuclei are usually plentiful, the Schweidler equilibrium equation, $q\theta = n$, applies approximately. An average value of 60 sec. for θ, the mean life of a small ion, and of 650 per c.c. for the small ion concentration, requires that the rate of creation, q, should be 650/60 or 10·8 ions/c.c./sec. in reasonable agreement with direct measurements of q, shown in Table I. No direct measurements of θ have yet been made over the oceans. The concentration of nuclei in mid-ocean has been found to be from 400 to 800 per c.c. and the mean life-time of a small ion should be about 300 sec.[10] Since n was found on the *Carnegie* to amount to some 550 small ions/c.c., the ionising power at sea should amount to 550/300 or 1·83 I, in agreement with the value of q in the last column of Table I.

The problem of the ionisation of the lower atmosphere cannot be said to be completely solved until much more has been done to settle the manner in which the size and numbers of the nuclei affect their interaction with small ions. The general nature of the factors in the ionisation-balance has, however, been established, and an explanation can be given of the paradox that the conductivity of the air undergoes no large change as one passes from mid-ocean to land, despite a four-fold increase in the rate at which ions are formed. The increased birth-rate of the small ions is counterbalanced by an increased death-rate, owing to the greater concentration of condensation-nuclei over the land areas.

CHAPTER II

ELECTRIC FIELDS AND ELECTRIC CURRENTS IN THE ATMOSPHERE

13. The Fine-weather Field. It was first found in the year 1752 by Lemonnier that the air above the earth is the seat of a persistent electric field during fine weather. The direction of this field shows that the earth carries a negative charge and the upper layers of the air a positive one. The state of affairs close to a flat portion of the surface of the earth can be expressed in three ways: (*a*) the earth carries a charge of surface density σ per unit area; (*b*) there is a vertical field of strength $F = 4\pi\sigma$, just above the ground; or (*c*) between two horizontal planes close to the ground there is a difference of potential

$$dV = V_{h+dh} - V_h = - Fdh = - 4\pi\sigma dh,$$

where $h + dh$ and h are the heights of the planes.

The quantity dV/dh is called the potential gradient and is positive, since σ is found to be negative. For the same reason, the field F is directed downwards, and this downward direction is by convention adopted as the positive direction for electric fields in the atmosphere. In these definitions it is assumed that the portion of the ground considered is flat and far removed from projections, such as trees and buildings, which would disturb the distribution of charge and concentrate the lines of force at certain points.

The average value of the fine-weather potential gradient is about 100 v./m.; the corresponding value for the average charge density is $2{\cdot}7 \times 10^{-4}$ electrostatic units/sq. cm. or 0·0009 coulomb/sq. km. The total fine-weather charge on the earth is of the order of 500,000 coulombs. Measurements of the fine-weather field are made by determining either σ or dV/dh; they are always expressed in terms of the latter, in volts per metre.

14. Direct Measurement of the Surface Density of the Earth's Charge. The charge on such a limited portion of the ground as can be isolated for the determination of σ is so small that a sensitive electrometer must be used to measure it. Fig. 3 illustrates the "Universal portable electrometer" devised by C. T. R. Wilson for this purpose. A flat circular plate P, called the test-plate, is surrounded by a guard-ring and mounted flush with the surface of the earth but insulated from it. This plate is joined to a gold-leaf electroscope G, whose leaf moves inside a positively charged case and is observed through a telemicroscope. C is a variable cylindrical condenser,

called a compensator, with its inner plate joined to the gold-leaf system, and its outer plate maintained at a constant potential, $-V$.

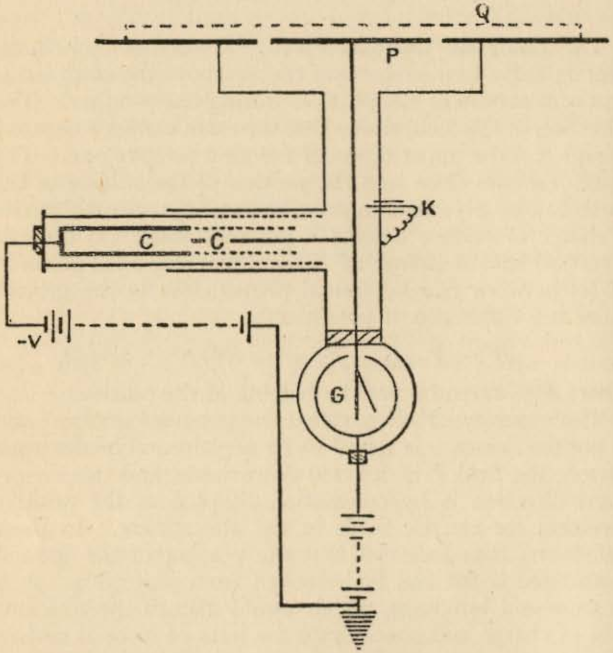

FIG. 3.—Universal portable electrometer (Wilson).

To make a measurement, the instrument is initially shielded from the earth's field by placing over it the earthed metal cover Q, indicated by the dotted lines. The reading of the leaf corresponding to earth or zero potential is found by momentarily earthing the plate P and the gold-leaf system with the key K. This earthing key is then withdrawn, the cover removed and the plate exposed to the field, with the compensator capacity zero. A negative charge thus appears by induction upon P, an equal positive charge is set free upon the central system, and the leaf moves inwards. It can be restored to its zero position if a negative charge is induced on the central system by increasing the capacity of the compensator to a value C'. The charge on the test-plate is then $-C'V$ and the surface density, σ, is $-C'V/A$, where A is the area of the test-plate.

In its original form the apparatus is small and portable, and the two batteries shown in the figure are replaced by small Leyden jars of silvered quartz, which keep their charge for a considerable time. For absolute measurements, with the plate mounted at ground level, a pit must be provided to house the observer; very often relative measurements are made with the instrument mounted on a tripod, and the factor necessary to reduce the observations to standard conditions determined from simultaneous observations in a pit or with a potential gradient method. Since the lines of force are concentrated upon any projection above the earth, the factor is greater than unity; in the case of a tripod 1 m. high it amounts to 3 or 4. A useful method of calibrating the instrument is to place it in artificial electric fields of known strength. Two large flat metal sheets, one flush with the test-plate and the other above it, are charged to a measured difference of potential by means of a battery of small cells.[1]

15. Measurement of the Potential Gradient. The potential gradient dV/dh may be found by measuring the difference of potential between two insulated conductors at different heights above the ground. Various forms of electrometer are employed, and one conductor may be the earth itself, while the other is a stretched horizontal wire about a metre above ground-level. Sometimes two wires at different heights are used. It is of course essential that the supports of the wires and the presence of the observer and his instruments should not materially alter the field to be measured. In the arrangement in Fig. 4 (*a*), the wire is hung between amber or sulphur insulators at the ends of two vertical rods; its length should exceed five times its height above ground.

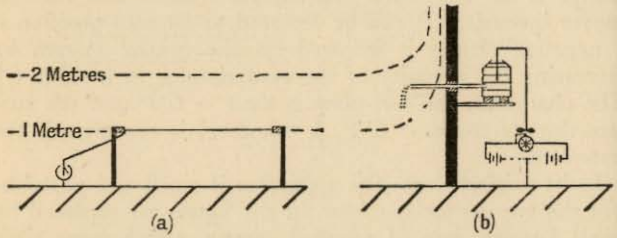

FIG. 4.—Measurement of the potential gradient.
(*a*) Absolute determination in open field.
(*b*) Continuous recording with the Kelvin water-dropper.

The wire when first set up is at a different potential to that of the air in its neighbourhood, and a current will flow between them which tends to remove this potential difference. The ordinary conductivity of the air is, however, too small for this process of equalisation to take place very rapidly and the electrometer reading will always lag behind a fluctuating field. It is necessary for this reason to place at the centre of the wire some active ionising agent which speeds up the process by increasing the local conductivity of the air. This may take the form of a glowing fuse of filter-paper, impregnated with a 5 per cent. solution of lead nitrate, or of a disc or spiral of metal coated with a deposit of polonium or radio-thorium giving off α rays. Such "collectors", as they are called, have the advantage of causing the wire and the electrometer to acquire the potential of the air at the centre of the stretched length, where the electric field is least disturbed by supports and observer. The time taken for equalisation of potential depends upon the type and activity of the collector and varies from 1 to 60 sec. There is always some uncertainty as to the exact position at which the ionising agent exerts its effect, especially if a wind is blowing, but this can be avoided by making observations at different heights.

16. Continuous Recording of the Potential Gradient. An adaptation of the arrangement just described is employed to obtain continuous records of the potential gradient, the electrometer being housed in a building and the collector carried on an insulated rod projecting from the wall. The earth's field is very much distorted by the presence of the building, and a reduction factor for the installation must occasionally be determined by making simultaneous measurements in an open field. Fig. 4 (*b*) shows the nature of the distortion of the equipotential surfaces due to a building.

The Kelvin water-dropper is still sometimes used at recording stations as a potential equaliser. A jet of water from an insulated cistern within the building escapes from the end of a pipe passing through and insulated from the wall, and breaks up into fine drops at the point where the potential is required (Fig. 4). On starting the jet, the potential of the insulated system will in general be somewhat lower than that of the air at the end of the pipe; this end will carry an induced negative charge and the cistern a positive one. Each drop carries a negative charge away and leaves the system slightly higher in potential than before. Ultimately the negative charge at the end of the pipe disappears and the system is at the potential of the air at the point at which the drops break away. In practice this takes a time of the order of 30 sec.

Radioactive collectors are also employed, but whatever the type of collector, the insulated system is usually joined to the needle of a quadrant electrometer of low sensitivity, and opposite pairs of quadrants connected to a battery whose centre is earthed. The record can be made intermittently, by means of a clockwork arrangement which depresses an inked pointer attached to the needle (Benndorf) or continuously, by receiving the spot of light from a small mirror on a moving strip of bromide paper.

17. The Electric Fluxmeter or Field Mill. If the cover Q in Fig. 3 were rapidly and periodically swung away from and over the plate P, the bound charge on P would alternately appear and disappear. If P is earthed through a high resistance R, an alternating potential difference of amplitude proportional to the field will appear across R. This can be amplified and if necessary rectified so that an output meter will show the magnitude of the field, an auxiliary device indicating its sign. Calibration can be carried out by comparison with a stretched wire in the open (§ 15).

Developments of this principle which was first employed by Russelvedt in Norway, have been used to measure electric fields during aircraft flights and under thunderclouds. In a recent form, capable of recording rapidly-varying fields, P is a ring of separate metal studs and Q is a rotating disc with a corresponding set of holes.[2]

18. Variation of the Potential Gradient with Height above the Ground : Space-charge. A good many observations of the potential gradient have been made with balloons fitted with collectors of the radioactive or the glowing fuse pattern ; they all indicate a rapid decrease in the field with increasing height above the ground (Table III, § 25). Though no great accuracy can be claimed for these measurements—for they are subject to errors arising from the distortion of the field by free and induced charges on the balloon and are but momentary observations of a quantity subject to considerable variation—it is well established that at a height of 18 km. the field has fallen to less than 1/100 of its value at ground level and is still diminishing slowly.

This diminution in the potential gradient with height indicates that a free positive charge, practically equal to the negative charge on the surface of the earth, resides within the lower 18 km. of the atmosphere. Integration of the values of dV/dh obtained in balloon ascents gives a total potential difference between the earth and the air at a height of 18 km. of about 4×10^5 v. ; at this height, and above it, the conductivity of the air is so great that this figure may be taken to represent the potential of the highly conducting "Kennelly-Heaviside layer" some 80 km. above the ground.

The density, ρ, of the positive "space-charge" referred to can be determined from Poisson's equation, which, if the lines of force are vertical, takes the form

$$\frac{d}{dh}(dV/dh) = -4\pi\rho.$$

Several investigators have examined the nature of the space-charge quite close to the ground, using collectors at different heights. The results obtained are conflicting as to the magnitude, and even the sign, of ρ in this region ; evidently local conditions are of main importance.

19. Variations of the Potential Gradient with Locality, Time and Season. Before any discussion of the more important variations of the potential gradient, mention should be made of the fact that incessant fluctuations are observed over short periods of time ; these are due to local changes in the space-charge and the conductivity of the air in the vicinity of the collector.

For many years continuous records of the potential gradient have been taken at certain stations in the Northern Hemisphere. Less extensive information is available for the Southern Hemisphere, but observations have been made over considerable periods in the Arctic and Antarctic regions. Some very important measurements over the oceans have been carried out by the survey ship *Carnegie* of the Carnegie Institute of Washington. It appears that the sign of the potential gradient in fine weather is positive all over the earth's surface, but that over land areas its value varies considerably with local conditions. The mean of dV/dh at Kew is 317 v./m., while that at Davos in Switzerland is but 64 v./m. Over the oceans a value of

126 v./m., which varies little if at all with geographical position, has been found. The average value for the whole earth is not far from 120 v./m.

It would seem that the potential gradient observed on land is not a quantity of much fundamental significance, its value depending primarily upon local conditions of atmospheric conductivity. This is evident from the fact that a simple periodic variation according to *local* time is the basis of all fine-weather land records. The minimum values are obtained in the early morning at about 4 a.m. and the maxima in the evening between 6 and 8 p.m. In many places a second maximum at 8 a.m. and a second minimum at midday are found. The amplitude of these daily variations at land stations sometimes reaches 50 per cent. of the mean value for the day.

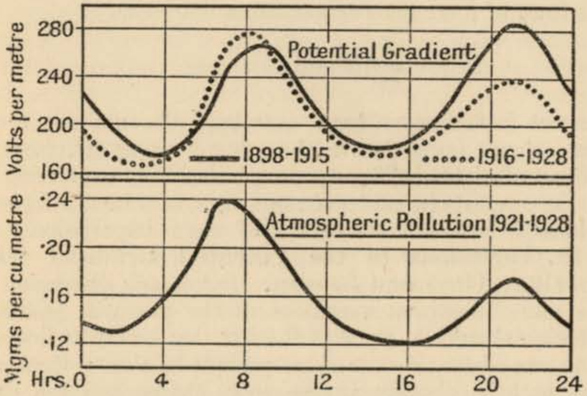

FIG. 5.—Relation between potential gradient and atmospheric pollution (Whipple).

The local time variation has been shown by Whipple [3] to be closely correlated with the amount and distribution of the smoke pollution of the atmosphere near large cities, where these continuous records have generally been made. Fig. 5 shows the variation at Kew of the potential gradient during the summer months for the two periods 1898-1915 and 1916-28, together with the variation in the amount of pollution (determined by aspirating the air through filter-paper) for the period 1921-28. The figure shows not only the close relation which exists between potential gradient and pollution but also the striking effect of the introduction of "summer time" into Great Britain in the year 1916, after which the morning minimum and maximum moved back by approximately one real hour. The atmospheric pollution curve has maxima and minima which have been explained by Simpson as due to the combined effect of variations in the amount of smoke produced in the city and variations in the stability of the atmosphere, that is in the mixing action of surface winds and general turbulence of the lower air.

As regards the annual variation of the potential gradient, land stations in both hemispheres show a maximum in the local winter and a minimum in the local summer. The only significant exception is the Antarctic region, where a reversal of phase occurs, giving rise to a maximum in the local summer and a minimum in the winter.

In view of the local origin of the variations of the gradient found at land stations near towns, observations over the oceans, where no pronounced local effects are to be expected, are of very great importance. Mauchly [4] analysed the measurements of the *Carnegie* cruises and found that there is a well-marked diurnal variation at sea, with maxima and minima occurring at the same moment in all parts of the globe. Thus the potential gradient in all oceans is found to be about 15½ per cent. below the mean at 5 hours, G.M.T., and about 20 per cent. above it at 19 hours, G.M.T. It is remarkable that the same 24-hour wave, progressing according to universal solar time, had been observed by Simpson in the Antarctic and Lapland. Fig. 6 (*a*) (after Whipple) illustrates these results, which were confirmed by the last cruise of the *Carnegie*. In each case shown in the figure, the mean potential gradient has been reduced to 100 v./m. No appreciable annual variation has so far been observed over the sea.

Mauchly's discovery of a variation of potential gradient according to universal time is generally accepted as being of fundamental significance. The variation must clearly be ascribed to an alteration in the difference of potential between the upper conducting layers of the atmosphere and the earth; it affords an important means of testing any theory of the origin and maintenance of this potential difference.

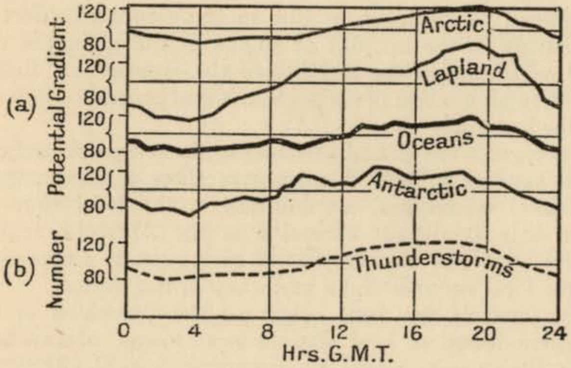

Fig. 6.

(*a*) Variation of potential gradient with universal time.
(*b*) Variation of thunderstorm activity over the earth's surface (Whipple).

20. The Fine-weather Current: Conduction and Convection Currents. In the ordinary fine-weather field positive ions are driven towards the earth and negative ions away from it; the motion of these ions constitutes a downwardly directed conduction current. The ionic conduction current passing through 1 sq. cm. of a horizontal plane can be written as $I_0 = F(\lambda_+ + \lambda_-)$, where F is the strength of the electric field and λ_+ and λ_- are the polar conductivities of the air at the point in question (§ 3).

There is, however, a fine-weather current of a different nature which plays a part in the transfer of electricity by the atmosphere. If the air should contain at any point an excess of ions of one sign (a space-charge), movement due to wind or ordinary turbulence will give rise to a mechanical transference of electric charge. Thus if v is the upward vertical component of the velocity of the air and ρ the space-charge per c.c., the upward convection current due to this cause will be $v\rho$ per sq. cm. The real current-density in fine weather is thus the resultant of the downward conduction and the upward convection currents, and is given by $I = I_0 - v\rho$.

The mean value of the total fine-weather current over the whole globe is not far from 2×10^{-16} amp./sq. cm. or 2 microamp./sq. km., so that the total current flowing in this way between the upper atmosphere and the whole earth is about 1000 amp. It would seem, from measurements which have been made in various parts of the world, that this current varies much less with changes in geographical position, in time of day and season of the year, than does the potential gradient. Although in the past it has not received a great deal of attention, it would appear to be a more useful quantity than the potential gradient and less affected by purely local conditions.

21. Direct Determination of the Conduction Current at the Surface of the Earth. Direct measurements of the magnitude of the conduction current which flows into the earth's surface have been made with the Wilson universal electrometer, with the test-plate mounted flush with the surface of the ground, as described in § 14. The curve of Fig. 7 illustrates the procedure followed in the measurements. At time t_1 the test-plate is exposed to the earth's field by removing the cover, and the capacity of the compensating condenser is adjusted to the value C necessary to bring the gold leaf back to the zero position. The charge on the plate is then $-CV$ and the field strength $F = 4\pi\frac{CV}{A}$, where, as before, A is the area of the plate and $-V$ the potential of the outside of the compensator. The test-plate is now left exposed until time t_2 and kept continuously at earth potential by increasing the compensator capacity to balance the charge received from the positive ions driven from the air on to the plate. Owing to variations in the strength of the field, and so in the induced charge on the plate, this increase is not a regular one. At time t_2 the plate is again shielded with the cover and the compensator capacity is reduced from C_1 to C_2 to maintain the shielded system at earth potential. At this moment the field strength is $4\pi(C_1 - C_2)V/A$. Since at the beginning of the measurement the compensator capacity was zero, it is evident that during the interval, $t_2 - t_1$, the plate received a positive charge C_2V

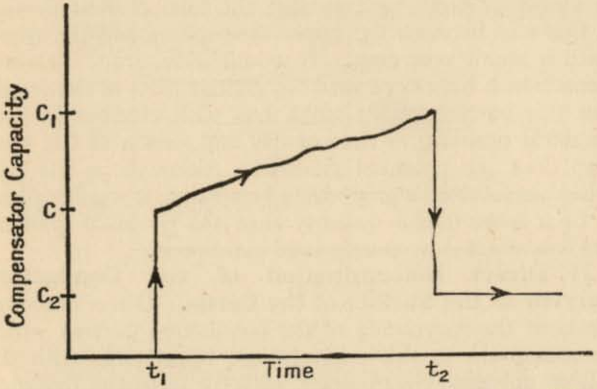

FIG. 7.—Measurement of conduction current with the Wilson universal electrometer.

and the average value of the conduction current per square centimetre was $C_2V/A(t_2 - t_1)$. For routine observations the instrument is mounted on a tripod above the ground, and the readings are reduced to standard conditions by occasional determinations of the reduction factor, from observations in a pit.

22. Indirect Determination of the Conduction Current at a Point in the Air. The conduction current at a point in the air can be determined also by separate measurements of the field strength, F, and the polar conductivities, λ_+ and λ_-. The methods used to determine

F, or the potential gradient, have already been described in this chapter; the conductivities are usually found by the Gerdien method sketched in § 2. In another form of the Gerdien method, due to Schering, the cylindrical condenser is replaced by a large earthed wire cage, along the axis of which is a charged insulated wire connected to an electrometer. The rate at which the charge is dissipated by ions of opposite sign is determined in exactly the same manner as in the Gerdien method, and the same equations apply if certain conditions are fulfilled. The cage must be large enough, and the charge on the wire small enough, to ensure that no considerable alteration in the number of ions is caused by the flow of current. The arrangement must be set up in the open air to ensure that ordinary atmospheric circulation prevents the development of the electrode space-charges to be discussed in the next section. And finally, the whole cage must be shielded from the earth's field by a rough roof or by trees, otherwise it will carry an induced negative charge on the outside and rob the entering air of negative ions.

23. The Comparison of the Direct and Indirect Methods: Electrode Space-charge. The direct method due to Wilson measures the conduction current entering the earth; the indirect method measures the current at a certain height above the earth. In the latter case the current is carried by two oppositely moving streams of ions of opposite sign; in the former it consists of a single stream, for while positive ions enter the earth, negative ions do not pass from it into the atmosphere. The two methods, therefore, do not necessarily measure the same quantity. One determines the true conduction current at a height, and the other its positive component at ground-level.

Consider a vertical cylinder of perfectly still air whose height is h and cross-section 1 sq. cm., with its base on the ground (Fig. 8). Let F' and F be the electric field strengths at top and bottom of this cylinder, and λ'_+, λ'_- and λ_+, λ_- the polar conductivities. The conduction current through the top is $F'(\lambda'_+ + \lambda'_-)$; in each second a positive charge $F'\lambda'_+$ enters, and a negative charge $F'\lambda'_-$ leaves. Through the bottom there is only a downward flow of positive ions, carrying away a positive charge $F\lambda_+$ per sec. The cylinder as a whole thus loses a positive charge $F\lambda_+ - F'\lambda'_+$ per sec., and a negative charge $F'\lambda'_-$ per sec. This may be expressed as a development of a positive space-charge at a rate

$$F'\lambda'_- - (F\lambda_+ - F'\lambda'_+) = F'(\lambda'_+ + \lambda'_-) - F\lambda_+$$

per sec. The growth of this "electrode" space-charge should automatically decrease the field F' and should cease only when F' has such a value that as many negative as positive ions leave the cylinder in each second, i.e. when

$$F'(\lambda'_+ + \lambda'_-) = F\lambda_+ . \quad (2.1)$$

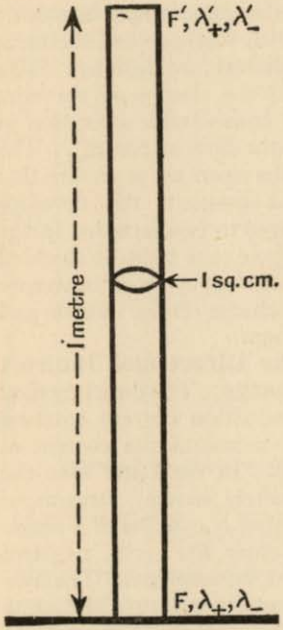

FIG. 8.—Electrode space-charge.

The two sides of this last equation are respectively the conduction currents at height *h* and at ground level. Thus, for perfectly still air, the two methods we have described should give the same numerical values, though they measure different quantities.

It was thought for some time that λ_+ must necessarily be considerably smaller than $(\lambda'_+ + \lambda'_-)$ and hence that F must be about double F'. Scrase[5] has, however, found practically no difference between F and F' and very little sign of electrode space-charge. A suggestion by Whipple that the space-charge is removed by atmospheric turbulence as rapidly as it is formed is unable to explain these results.

The difficulty appears to have been removed by the discovery by Hogg[6] that, owing to the local effect of α and β rays from radioactive matter in the soil, λ_+ is much larger than was thought and approximately equal to $(\lambda'_+ + \lambda'_-)$. Since $F \cong F'$, eqn. 2.1 is satisfied and the problem of electrode space-charge does not arise.

Values of the air-earth current in fine-weather obtained by the direct method in various parts of the world range from 1·0 to $4{\cdot}0 \times 10^{-16}$ amp./cm.^{2} Those by the indirect method vary from 0·4 to $3{\cdot}2 \times 10^{-16}$ amp./cm.^{2} Though as indicated above and found in practice, the two methods should give the same result, the variability of the ionising agents producing λ_+ and of convection currents suggests that the direct method is the more reliable of the two.

24. Variations in the Fine-weather Current. Both direct and indirect methods of studying the air-earth current indicate that in fairly fine weather it is less subject to variations than is the potential gradient. Simultaneous measurements of the field and of the total conductivity of the air, $\lambda = \lambda_+ + \lambda_-$, show that these quantities vary to some extent in inverse ratio, with the result that their product, the conduction current, is less variable than either. Factors such as an increase in the number of condensation nuclei or the presence of fog particles, which decrease λ by raising the proportion of the slow ions present, cause a corresponding increase in the potential gradient. The simple form of the daily variation in the earth's field has its counterpart in an inverse variation of the conductivity, with a maximum in the early morning between 3 and 4 a.m. The extreme effect of atmospheric pollution near large cities, which increases the potential gradient and diminishes the conductivity, has already been discussed (§ 19). In general however the reciprocal relation between λ and F is not exact enough to keep the conduction current invariable. At land stations in Europe the current is found to have an annual variation which coincides in phase with that of the potential gradient but has a smaller amplitude. At other stations its daily variation follows the changes in the conductivity.

CHRIST'S COLLEG

25. The Conduction Current at Great Heights. It has been found from simultaneous determinations of potential gradient and atmospheric conductivity during balloon ascents that the rapid decrease in F with height above the ground is accompanied by an increase in λ, of such magnitude as to keep the conduction current approximately constant. Table III shows the results of an ascent by Wigand,[7] from which it will be seen that when the field had fallen to 1/15 of its value at the ground, the conductivity had risen eleven-fold.

TABLE III

Conduction Current during Balloon Ascent (Wigand)

Height (Metres).	F (volts/metre).	λ (e.s.u.).	I (amps./sq. cm.).
0	136	$1{\cdot}1\ 10^{-4}$	$1{\cdot}7\ 10^{-16}$
2500	27	$4{\cdot}8$,,	$1{\cdot}4$,,
4400	18	$8{\cdot}2$,,	$1{\cdot}6$,,
6500	$8{\cdot}8$	$12{\cdot}6$,,	$1{\cdot}2$,,

These results have been confirmed and extended by conductivity measurements made during the flight of the United States army balloon Explorer II in 1935.[8] They showed that up to a height of 18 km., the ionisation of the air increases by roughly 500 ion-pairs per km. and that the conductivity at 18 km. was about 100 times the usual value at the ground.

26. The Significance of the Air-earth Current. The general constancy of the air-earth current with height above the ground and in different parts of the world suggests that, at any rate to a first approximation, it has its origin in a constant potential difference between the conducting layers of the upper atmosphere and the earth, and that its actual value depends upon the resistance of the air between the two regions. The conductivity of the upper portion of this air-path is entirely due to the cosmic radiation * and is unlikely to alter appreciably with time of day, locality or season. But below a height of about 2 km. over land areas, an additional ionising influence is exercised by radioactive matter in the air and in the earth, and this, as we have seen (§ 5), varies very much. Moreover, the conductivity of the air in this region is dependent upon the relative concentrations of the large and the small ions, and these alter with the number of nuclei present. The current-bearing column of air above the point of observation thus consists of an upper constant resistance and a lower variable one in series with each other. The extent to which the current carried by the air-column alters with local conditions will depend on the ratio which the lower variable resistance bears to the total resistance.

Both the results of Wigand in Table III and those from the Explorer II flight[8] indicate that the total resistance of a column of air of cross-sectional area 1 sq. cm. is about $1{\cdot}0 \times 10^{21}$ ohms. The conductivity between 14 and 18 km. is so high that this upper region contributes only a small fraction to the resistance and higher regions would be still less important. If the variable part of the column be the first 100 m. above the earth, where the specific resistance is usually 8×10^{15} ohm-cm., this portion will contribute 8×10^{19} ohms to the total. We see that even if the conductivity of the first 100 m. were halved, the effect upon the air-earth current would amount to but 4 per cent. The potential gradient near the ground, on the other hand, would be doubled, for from this point of view it represents the fall of potential per unit length of the lowest part of the current-bearing column. It is evident that potential gradient measurements over land, and in particular near cities, cannot be expected to yield information which bears directly upon the question of the total potential difference between upper atmosphere and earth. In the case of observations at sea and in polar regions the position is different; practically all the ionisation throughout the whole column is then due to the cosmic radiation, and the only local effect which can influence the fine-weather gradient is a change in the number of nuclei available for the capture of small ions.

---

* This refers to the regions from 15 to 30 kilometres above the ground. The E layer 80 kilometres up has a solar origin.

27. The Electric Field during Disturbed Weather. The normal downwardly directed field, due to a positively charged upper atmosphere and a negatively charged earth, is frequently disturbed when the weather ceases to be fine. During fog, as explained in § 24, it is very much increased, and may reach ten times its normal value; during dust-storms, of the type common in semi-arid regions and deserts, powerful reversed or negative fields are usual and reach 10,000 v./m. The effects found during cloudy weather and rain are variable, and range from gradients of the order of a few hundred volts per metre in a fine drizzle to as much as 50,000 v./m. under thunderclouds.

Generally speaking, negative fields predominate when light or steady rain is falling, though occasional positive excursions are observed. In the case of heavy rainstorms and thunderclouds, the sign of the field depends upon the portion of the cloud passing over the point of observation, but here, too, there is evidence that negative gradients are the more frequent.

The field during thunderstorms fluctuates a great deal if the cloud is active in producing lightning. Its value at the ground does not as a rule exceed 10,000 to 20,000 v./m. except for very brief intervals occupying fractions of a second. Equally high fields are observed during heavy rainstorms unaccompanied by lightning. During a snowstorm the field is usually positive and in a heavy storm may attain 10,000 v./m. The methods employed for the study of the large and rapidly varying fields of thunderclouds are described in Chapter III.

28. The Charge on Rain and Snow; the Precipitation Current. The apparatus required to examine the charge carried to the earth by precipitation—rain, hail, snow, and sleet—is comparatively simple, and consists essentially of an insulated metal vessel to catch the rain, etc., and an electrometer to measure the charge received. Great precautions must, however, be taken to eliminate the disturbing effect of the negative charge given to the air as the drops splash on the container (Lenard effect). If some of this is lost a spurious positive charge will be indicated. For a similar reason, the entry of spray due to the splashing of rain falling outside the receiving vessel must be prevented. The receiver must be screened electrostatically from the electric field outside. The rate of rainfall, and sometimes the size of individual drops, is also observed. By amplifying the induction effect of a drop as it passes through an insulated cylinder the charges carried by individual drops may be measured. As the charges brought down vary considerably, it is necessary in all such work to carry out a long series of observations.

Since the year 1908, when the modern series of observations began, all observers have found a preponderance of positive charge on rain in general. The average ratio of the quantities of positive and negative electricity brought down by all kinds of precipitation varies according to the situation of the observer. Some of the values found for this ratio are: Potsdam (Schindelhauer), 1·4 : 1; Puy-en-Velay (Baldit), 2·4 : 1; Dublin (McClelland and Nolan), 4·8 : 1; Simla (Simpson), 2·4 : 1; Otago, New Zealand (Marwick), 3·2 : 1. As exceptions to the general rule, it may be noted that snow usually carries a considerable negative charge, and that the fine drops of a drizzle are also negative.

The subject of the charge on rain and its relation to the prevailing electric field has recently received special attention because of its connection with the electrification of thunderclouds. This work is discussed in § 45.

The charge per c.c. in the case of heavy thunderstorm rains reaches average values of 30 to 40 e.s.u., while single drops may carry 100 to 200 e.s.u. (Gschwend) and attain potentials as great as 300 v. The mean values reported by different observers for the net charge per c.c. on all forms of precipitation during a long series of observations range from + 0·029 e.s.u. at Potsdam (Schindelhauer) to + 0·176 e.s.u. at Simla (Simpson).

The transfer of electricity from atmosphere to earth in this manner constitutes a "precipitation" current which appears on the whole to be in the same direction as the fine-weather conduction current, since it carries more positive than negative charge to the earth. In the case of thunderstorms this current sometimes reaches values as high as 2×10^{-11} amp./sq. cm., and the total convection current carried by the rain in such a storm may amount to more than 0·1 amp. Before it is possible to frame a trustworthy estimate of the amount of the excess of positive over negative electricity conveyed to the whole earth in this way, much more information is required from tropical and equatorial regions.

29. Currents due to Point-discharge. It is well known that an electric glow or brush discharge takes place from a pointed conductor when placed in a sufficiently strong field. It consists of a stream of ions of the same sign as the charge upon the point. Discharges of this kind must, therefore, be expected from the ends of exposed conductors on the surface of the earth whenever the potential gradient and the height and sharpness of the ends are sufficiently great. Indeed the earliest investigators, Franklin, Dalibard and Lemonnier with high metal rods and kites detected electric fields in thundery and in fine weather, by means of this current. Under favourable conditions, afforded by mountain peaks or the masts of ships exposed to the intense fields of a thundercloud, the glow discharge may become very conspicuous (St. Elmo's fire).

It was first pointed out by C. T. R. Wilson [9] that point-discharge currents of much smaller intensity must play an important part in the interchange of electricity between the earth and the atmosphere. The fields prevailing under rainstorms and thunderclouds very frequently reach values sufficiently great for considerable currents to be discharged from an assemblage of exposed conductors, such as trees, bushes, housetops and even fields of grass. A conductor need not end in a sharp point nor project to a great height in order that it should begin to act as a discharger. For example, an earth-connected sphere of radius 1 cm. need be raised only to a height of 3 m. in the not unusual field of 10,000 v./m. for the electric intensity at its surface to reach the critical value of 30,000 v./cm. at which brush discharge begins. A practical instance of the correctness of this suggestion is afforded by some experiments made by the author, in which a small tree, 4 m. high, was cut off at its base, mounted on insulators and connected to earth through a galvanometer. Exposure to the fields due to nearby thunderstorms yielded the average point-discharge currents shown below: [10]

TABLE IV

POINT-DISCHARGE CURRENTS FROM A SMALL TREE (SCHONLAND)

Field (volts/metre).	Current (microamperes).
− 3,500	0·07
− 5,500	0·20
− 11,000	1·00
− 16,000	4·00

The contribution of a single tree such as this must be multiplied by a very large factor to obtain the total current flowing between the earth and a thundercloud; in the case quoted, the tree was typical of the exposed natural conductors for many miles around, and a rough surface integration over the area affected by the cloud indicated that the total point-discharge effect was of the order of 2 amp. in an upward direction.

Since the direction and magnitude of the large fields associated with disturbed weather vary considerably, it is important to know the relative amounts of positive and negative electricity discharged from an exposed point over a long period of time. In a series of observations by Wormell,[11] a sharp point carried on insulators at the top of a pole was connected by cable to one electrode of a voltameter filled with dilute sulphuric acid, the other electrode being earthed. The voltameter, shown, with some minor but significant details omitted, in Fig. 9, was constructed of fine capillary tubing (diameter 0·8 mm.) and the gases evolved were separately collected, their volumes being determined from the lengths of the bubbles formed. If v_1 and v_2 are the volumes of the mixed gases collected at the earthed and the point-connected electrodes respectively, the quantities of positive and negative electricity, q_1 and q_2 which have been discharged from the point can be separately determined in the following way: If one unit of quantity liberates in electrolysis c c.c. of oxygen and $2c$ c.c. of hydrogen, we have

$$q_1c + 2q_2c = v_1 \quad \text{and} \quad 2q_1c + q_2c = v_2,$$

from which we may determine q_1 and q_2.

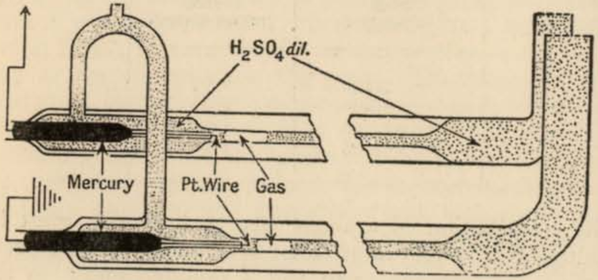

FIG. 9.—Water micro-voltameter (Wormell).

The quantities discharged in this way have been examined by Wormell at Cambridge over a period of three years. Some of his results are shown in the Table V.

Each year shows a considerable net loss of positive electricity from the discharger.

In a more detailed discussion it is noted that of 147 separate periods of disturbed weather accompanied by precipitation, 103 showed an excess of upward current (+ ve discharge), 34 an excess of downward current (− ve discharge), and in 10 the net discharge was zero. This is what would be expected from the predominance of negative potential gradients in disturbed weather.

Similar measurements have been made in other parts of the world (§ 30).

TABLE V

INTEGRATED EFFECTS OF POINT-DISCHARGE (WORMELL)

Year	1927.	1928.	1929.
Positive quantity discharged, q_1 (coulombs)	0·28	0·24	—
Negative quantity discharged, q_2 (coulombs)	0·14	0·11	—
Net positive discharge, $q_1 - q_2$ (coulombs) .	0·14	0·13	0·11

30. The Interchange of Electricity Between the Earth and the Atmosphere; the Maintenance of the Earth's Charge. The negatively charged earth and the positively charged upper layers of the atmosphere form two plates of a spherical condenser with the lower air as the dielectric. Although the conductivity of the air between the plates is small, the applied potential difference is great enough to make the leakage of charge through it very considerable. The average value of the charge per unit area of the earth's surface is 9×10^{-14} coulombs/sq. cm., and that of the fine-weather conduction current is 2×10^{-16} amp./sq. cm. Left to itself, a condenser of this kind would be discharged by internal leakage in a time of the order of 10 min. But this is not all; to the dissipation of the earth's charge by the fine-weather current we must add the effect of the charge conveyed by rain and snow, for it has been shown that on the whole the net charge conveyed to the earth by precipitation is positive in sign. Thus to the conduction current of 1000 amp. over the whole surface of the earth must be added a precipitation current in the same direction, estimated by Wigand[12]—though any such estimate can only be provisional—at 400 amp., making a total of 1400 amp. tending to dissipate the 500,000 coulombs with which the earth is charged.

In spite of the continuous operation of these two factors, the earth's charge remains practically constant, so it is clear that there must exist some reverse or compensatory process which neutralises their effect. Some agency must be continuously at work replenishing the charges on the earth and in the upper air. The discovery of the mechanism responsible for this replenishment has been one of the chief problems of atmospheric electricity, and many proposals have been made to this end.

It was first suggested by C. T. R. Wilson[13] that it is to regions of disturbed weather that we must look for the mechanism of replenishment, that under rain and thunderclouds, where the potential gradient is more often reversed than in the normal direction, there are two processes at work which convey considerable quantities of negative charge to the earth. The first of these is the action of point-discharge from conductors projecting from the ground. This has already been discussed, and it has been shown that experimental tests indicate that it is of great importance. The second process is the charge conveyed to the ground by lightning flashes from thunderclouds. Every second, as will be seen in Chapter III, some 100 lightning discharges occur over the whole surface of the earth, each involving the passage of a charge of the order of 30 coulombs. Only a fraction of these, perhaps one in four on the average, strike the ground. The effectiveness of this process of transference of charge will depend upon whether more charges of one sign than another are conveyed to the earth. If, for example, practically all the charges transferred were negative, the process would be equivalent to a continuous compensation current of about 500 amp. Though there is evidence from a number of regions (§ 33) that this is actually the case, the question is still under investigation.

An estimate of the annual electrical "balance-sheet" of a square kilometre of ground at Cambridge in England has been made by Wormell,[11] on the basis of his point-discharge measurements and observations on lightning discharges. The air-earth conduction current loss and the effect of rain and snow were estimated from average values of these quantities. The results were:

	Coulombs/sq. km./annum.
By natural point-discharge, gained . . . —	100
By lightning, gained . . . . . —	20
By atmospheric conduction, lost . . . —	60
By precipitation, lost . . . . . —	20
Net gain of negative charge . . . . —	40

Though such an estimate is only a very rough one, it appears to be quite possible that in this locality the four processes approximately balance one another, or even that the earth gains a negative charge.

These results have been supported and extended by similar measurements at Kew Observatory, at Durham, at Pretoria and in Nigeria.

Over the oceans, where thunderstorms are infrequent and elevated points are absent, the balance-sheet may be expected to show a net loss of negative charge, so that the position for the whole globe would be one of approximate equilibrium.

This suggestion of Wilson involved more than the interchange of electricity between the bases of cumulonimbus clouds, showers and thunderstorms, and the ground; he regarded such clouds as equally active in supplying positive electricity to the upper air. The existence of this upward current has been established by recent high-altitude flights above thunderclouds. Gish and Wait,[14] by measuring both the electric field and the conductivity of the air, have shown that an average current of 0·8 amp. flows in the expected direction. The cloud thus acts as an electrical generator which removes positive electricity from the earth and supplies it to the conducting layers of the atmosphere above, in which it is rapidly distributed in such a way as to maintain them at a constant potential of about 4×10^5 v., in spite of losses.

We should therefore expect the potential difference, and so the potential gradient, to show a maximum when the thundery regions of the earth are at their maximum activity. The diurnal variation of the gradient discovered by Mauchly (§ 19) should agree in phase with the diurnal variation of thunderstorm activity over the earth. It has been shown by Whipple[15] that this appears to be the case. Whipple's examination of the diurnal variation of the world's thunderstorms is represented by the bottom curve of Fig. 6 (*b*), where it will be seen that the parallelism with the variation of the potential gradient over the oceans and the polar caps is indeed very close.

Although the evidence discussed above makes it very probable that Wilson's replenishment theory is correct, it must be admitted that further quantitative measurements in different parts of the globe are needed to establish it.

A rather revolutionary extension of Wilson's ideas has been put forward by Frenkel,[16] who suggests that the generators chiefly responsible for the circulation of electricity between the earth and the upper air, in the reverse direction to the fine-weather current, are not thunderstorms but ordinary clouds. According to this theory all fog-like clouds carry a positive charge above and a negative charge below (§ 44) and thus create a conduction current which is opposite to that of fine weather. The fields due to these cloud dipoles (of which there are estimated to be a hundred thousand at any moment over the earth's surface) will, in Frenkel's view, induce and maintain the negative charges observed on the distant " serene sky " regions of the earth and positive charges in the air above them.

It has been shown, however, in § 24, that the enhanced fields below ordinary fog-like clouds are due to an alteration in the conductivity of the air and are in the normal positive direction. Such clouds do not give reversed electrical fields of the kind required by Frenkel's theory unless they are shower-clouds from which rain is falling (§ 45).

CHAPTER III

THE ELECTRIFICATION OF THUNDERCLOUDS

31. The Number of Thunderstorms over the Globe. Although a thunderstorm is a comparatively rare event at any one station in temperate latitudes, the number of thunderstorms per day experienced by the earth as a whole is very large. Even in such a limited area as France there are comparatively few days in the year on which thunder is not reported from some part of the country. According to a survey made by Brookes,[1] the earth experiences 16,000,000 thunderstorms per annum or 44,000 per day. Taking one hour as the average duration of a single storm there will on the average be 1800 thunderstorms in progress in different parts of the world at any one moment. As has been shown in § 19, Fig. 6, world thunderstorm activity alters regularly with the sun, reaching a maximum when the afternoon storms of equatorial Africa are ending and those of equatorial America are beginning. Brookes has estimated that about 100 flashes of lightning occur every second or 360,000 every hour.

The most thundery region of the earth is the island of Java, where thunder is heard at any one place on 61 per cent. of the days in a year. This percentage, the *isoceraunic level* of the place concerned, is 41 in parts of Central Africa, 39 to 37 in Southern Mexico and Panama, 29 in Brazil and 26 in Madagascar. In North America the isoceraunic level rises from 3 per cent. for Southern Canada to 25 per cent. for Florida. On the Californian coast it is about 1 per cent.

Over most of Europe thunder is heard on the average on about 11 days in the year; near the Alps the figure rises to 18 days. The figure for Johannesburg in South Africa is 50-60 days in the year. In using these figures account must be taken of the fact that on about 1 in 7 of thunderstorm " days " there is more than one storm within audible distance.

Over the oceans thunderstorms are infrequent except off the south-east coasts of Brazil and South Africa and in the seas surrounding Madagascar and the East Indian islands.

32. Methods used to Measure the Electric Fields of Thunderclouds. (*a*) *The capillary electrometer method.* This was devised by C. T. R. Wilson [2] for use in his classic investigations of thunderstorms and has also been employed by Wormell [3] and by the writer.[4] The general principle is similar to that of the test-plate or induced charge method of studying the fine-weather field (§ 14), in which an exposed conductor is kept at zero potential by alteration in the capacity of a compensating condenser, when the charge induced upon the conductor by the field is equal to that given by the compensator to the system. In the measurement of rapidly changing thunderstorm fields, however, compensation is produced automatically and very quickly by means of an ingenious form of capillary electrometer. As shown in Fig. 10, this consists of a small bubble of dilute sulphuric acid enclosed between mercury threads in a narrow capillary tube. The threads lead to end-cups of mercury, and one of these, A, is connected to a test-plate T insulated from, but flush with, the surrounding ground, while the other is connected to the earth. Between the mercury and the glass there is everywhere a thin film of dilute acid, so that an electrical " double layer " surrounds the mercury and makes each half of the electrometer a condenser charged to the potential difference of the double layer, about 0·90 v., the mercury being positively charged with respect to the acid. If a positive charge is given to the left-hand side, it will increase the charge on the left-hand condenser and the left-hand thread will move forward a certain distance so as to absorb this charge, by increasing the area of the acid-mercury surface and the capacity of the left-hand condenser. A corresponding movement of the right-hand thread causes a reduction in area on this side and the passage to earth of a quantity of electricity exactly equal to that originally supplied to the electrometer. The distance moved, *y*, is easily seen to be related to the charge passed through, q, by the equation

$$q = 2\pi rCV'(1 - r/R)y,$$

where r is the radius of the capillary and R that of the end-tube, and V' is the potential difference, and C the capacity per unit area, of the double layer. Thus $q = ky$, where k is an instrumental constant which can be determined by discharging a known quantity of electricity through the instrument. The arrangement, therefore, gives a linear relation between the movement of the acid bubble and the quantity discharged. In spite of the large value of C, about 30 microfarads/sq. cm., the electrometer is extremely sensitive. By using a microscope focused upon one end of the bubble, quantities of the order of 10^{-9} coulombs may be measured. A permanent record is best obtained by placing a slit and a moving photographic plate in the focal plane of the objective.

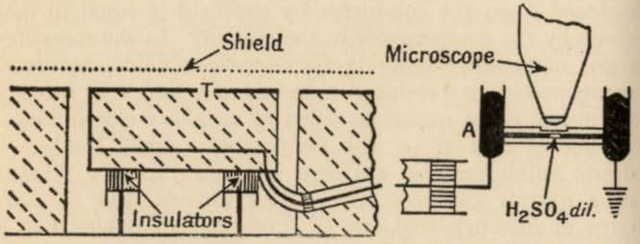

FIG. 10.—Measurements of the electric fields due to thunderstorms (C. T. R. Wilson).

When connected to a test-plate the electrometer automatically maintains it at earth potential and records the quantities of electricity passing to and from the earth as a result of changes in the external field and of the induced charges on the plate. The type of record obtained from this arrangement during a thunderstorm is illustrated by the thick line of Fig. 11. An earthed cover is swung over the test-plate for a few seconds at the beginning of each minute, causing the movements A′AA″, B′BB″, etc., as the induced charge flows away to earth and then returns. The points A, B, C, D, E would lie on a horizontal line if there were no actual transfer of charge between the plate and the atmosphere taking place, that is to say, no conduction current, point-discharge, or transport of charge by rain. The first 2 min. in the figure show the slight slope due to the conduction current only, the last two show the effect of a fall of positively charged rain. The charge, for example, conveyed to the plate by rain and conduction during the third minute is $k(y_D - y_C)$ and the mean value of the current per square centimetre $k(y_D - y_C)/60A$, where A is the area of the plate and k the constant of the electrometer. The dotted line joining the points A, B, C, D, E gives the reading of the instrument when the test-plate is shielded at any time during the record, and this line serves as the zero from which the field and field-changes are measured. The field at the end of the first minute, for instance, is given by

$$F = 4\pi k(y_B - y_{B'})/A.$$

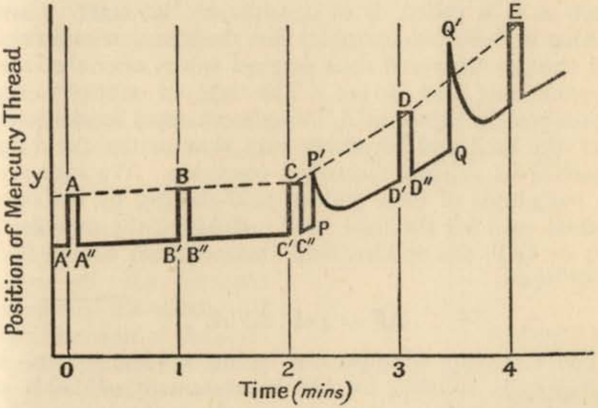

FIG. 11.—Capillary electrometer record during a thunderstorm.

Two sudden interruptions in the record, such as are caused by lightning flashes, are shown at P and Q. At P the record suddenly touches the dotted line, indicating that for a moment the field was completely destroyed and the original induced charge ran to earth through the electrometer. At Q the movement extends beyond the dotted line, showing that the field was actually reversed in sign by the discharge and reached a reverse value equal to half its original strength. The shape of the record immediately after the passage of these lightning flashes, the recovery curve as it is called, is of considerable interest; it will be seen in these two examples that the thundercloud fields and charges recovered their original values after the lapse of something like 20 sec. The rate of recovery was approximately exponential, being most rapid immediately after the flash and becoming very slow as the cloud approached its original electrified condition. We may find the magnitude of these sudden field-changes by the same method used for the field itself; if Δy be the movement PP′, or QQ′, the sudden field-change which caused it is given by:

$$\Delta F = 4\pi k \,.\, \Delta y/A.$$

The test-plate arrangement, using a plate 50 cm. in diameter, is suitable for the measurement of fields of strength exceeding 1000 v./m., such as are caused by thunderstorms when they come within a distance of about 8 km. An inverted test-plate of smaller dimensions mounted on a pole and with a cover periodically and automatically swung below it for a short time has been used by Wormell for measurements of the large fields due to near storms. This is of great use during heavy rain. For more distant storms Wilson employed a different form of exposed conductor, a copper ball 1 ft. in diameter mounted on insulators at the end of an iron pipe 5 m. in length (Fig. 12). When the arrangement is in use the pipe is held vertical; by turning it about a horizontal axis through its base, the pipe is lowered and the ball enters an earthed metal case which shields it from the field. Connection to the capillary electrometer is made by an insulated wire passing down the centre of the pipe.

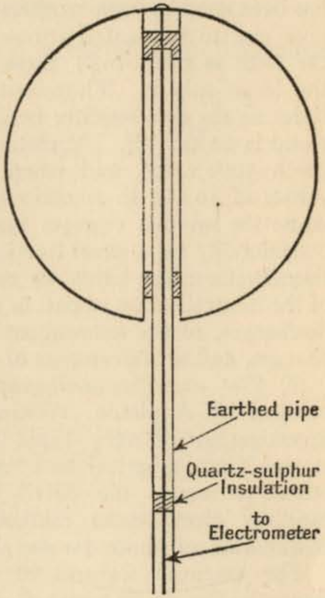

FIG. 12.—Elevated sphere for measuring fields of distant thunderstorms.

The field producing a given movement of the electrometer is calculated as follows: The charge q induced upon the ball when raised to a height h above the ground must be such as to maintain it at earth potential, for the ball is earth-connected through the electrometer. Thus if V is the undisturbed potential of the air at the point occupied by the centre of the sphere of radius r, we have

$$V + q/r - q/2h = 0,$$

the third term allowing for the effect of the electrical image of the charged sphere in the earth. If the movement of the electrometer caused by raising the ball from its case to the height h is y, we have

$$q = -ky$$

and $V = k(1/r - 1/2h)y$.

This observation therefore gives for the mean potential gradient between the ground and the height h,

$$F = V/h = (k/h)(1/r - 1/2h)y.$$

The same equation relates the sudden changes of field ΔF to the corresponding sudden movements Δy of the electrometer. Since these relations, like those derived for the test-plate, are derived on the assumption of a perfectly plane earth, small corrections must be applied to allow for the effect of the concentration of the lines of force upon the hut used to house the recording instrument.

The effects obtained from the elevated sphere become too small for accurate measurement when the storm is more than 20 km. away; for still greater distances a wireless aerial has been used by some workers. Such a wire can, however, give rise to unwanted corona (point-discharge) effects if the field is fairly big; these are avoided by the use of the large sphere. Thunderstorm fields are of the same order as the fine-weather field, about 100 v./m., when the cloud is 20 km. off. At distances of 6 to 8 km. they often reach 5000 v./m., and when the storm passes overhead values of 10,000 to 20,000 v./m. are commonly observed, while the sudden changes may exceed these figures very considerably for a small fraction of a second. In an active thunderstorm the fields are constantly altering as a result of the neutralisation of part or all of the charge by lightning discharges, of the subsequent rebuilding of the destroyed charges, and of movements of the cloud as a whole.

(*b*) *The amplifier-oscillograph method.* This was developed by Appleton, Watson-Watt and Herd[5] for the investigation of very rapid field-changes from distant storms (atmospherics) and has been used by them and others to record the details of field-changes which the capillary electrometer method, which has a time discrimination of about 0·1 sec., is unable to resolve.

The essential features of the arrangement used are shown in Fig. 13, in which C_0 is the capacity of an exposed conductor such as the ball of Fig. 12 (or for very distant storms, a horizontal wire aerial) and R_1 is a resistance of some 50,000 ohms inserted to render the aerial circuit aperiodic. C_1 is a condenser which is variable in steps to suit the field to be measured and R_2 is a high-resistance selected so that the time-constant C_1R_2 is large compared with the duration of the field-change to be recorded.

If the field alters by ΔF as a result of a change ΔV of the potential at the effective height h of the exposed conductor, a change $-\Delta q$ must take place in the charge on the conductor and the charge on the upper plate of C_1 must increase by $+\Delta q$.

This will produce a potential difference Δv across C_1 given by

$$\Delta v = \Delta q/C_1 = \Delta V - \Delta q/C_0,$$

since both these expressions give the change of potential at the point X.

Hence $$\Delta v = \frac{C_0}{C_0 + C_1} \cdot \Delta V = \frac{C_0}{C_0 + C_1} \cdot h\Delta F.$$

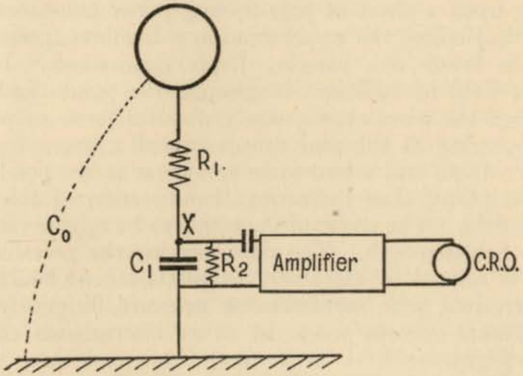

FIG. 13.—Input circuit for amplifier-oscillograph method (Appleton, Watson-Watt and Herd).

The arrangement thus acts as a condenser potentiometer and the amplified value of Δv causing the deflection of the oscillograph spot is proportional to the field-change. The oscillograph holds this deflection momentarily; its deflection drifts back to zero in a time set by the quantity C_1R_2 provided the time-constants of the amplifier are larger than this. C_1R_2 can usually be made long enough for the faithful recording of all but comparatively slow changes of field.

CHRIST'S COLLEGE

If C_1 and R_1 are removed from the circuit, the arrangement of Fig. 13 can be used to record the rate of change of field, dF/dt. For then

$$hdF/dt = dv/dt + (dq/dt)/C_0 = dv/dt + v/C_0R_2,$$

since the current i in the resistance R_2 is $v/R_2 = dq/dt$. If C_0R_2 is small enough, the second term is much greater than the first and $v \simeq hC_0R_2dF/dt$.

(*c*) *The Alti-electrograph.* This instrument was devised by Simpson and Scrase [6] for attachment to a small balloon to measure directly the electric fields at points near and within active thunderclouds. Two separate iron pins resting upon a sheet of pole-finding paper are connected to vertical wires, the upper one on a bamboo framework and the lower one hanging freely downwards. In an electric field of sufficient magnitude for point discharge to charge the wires appropriately, the difference of potential appearing at the pins causes a small current to flow between them and a blue stain to appear at the positively charged point, thus indicating the direction of the prevailing field. The width of the stain can be related roughly to the field-strength. The disc carrying the pole-finding paper is rotated by clockwork to give a record which can be correlated with simultaneous pressure, humidity and temperature records made by other instruments carried on the flight.

(*d*) *The electric fluxmeter method.* The principle of this method has been described in § 17. When the device is carried in aircraft inside clouds, care has to be taken to eliminate the " autogenous " field produced by the charge collected by the aircraft itself. This is done (Ross Gunn) by employing two fluxmeters, one on the upper surface of a wing and the other, facing downwards, on the lower surface. For one of these the external and the autogenous field will be in the same direction and for the other they will be in opposite directions. The deformation of the field due to the aircraft itself can be corrected for by model experiments. Owing to icing difficulties this device cannot be used at levels where the temperature is much below 0° C.

A high-resolution form of this instrument devised by Malan and the writer has been employed in observations at ground-level to fill the gap between method (*a*) which has a poor time-resolution for field-changes and method (*b*) which is more suitable for rapid than for slow field-changes. Records of the output of the fluxmeter are made on a magnetic tape recording machine and those portions of interest are played back and recorded photographically later on, thus providing economical high-speed recording of transient field-changes.

(*e*) *The point-discharge galvanometer method.* If a fine point erected on a tall pole is insulated and connected to earth through a recording galvanometer, the current I due to point-discharge is roughly related to the prevailing field F by the equation $I = a(F^2 - M^2)$ where a and M are constants for the particular arrangement used. This method, which has been examined in detail by Whipple and Scrase,[8] provides a useful general record of the sign and approximate value of F for near storms but its time-resolving power is low and the above equation does not hold with much accuracy when the usual thunderstorm winds are blowing.

33. The Distribution of Electricity in Thunderclouds. All the methods described in § 32 have contributed to the solution of the problem of the distribution of electricity in the thundercloud. After some controversy it is now generally agreed that the main distribution is one in which an upper positive charge lies several kilometres above a lower negative one. This pattern may be repeated in different parts (cells) of a large cloud. The arguments of C. T. R. Wilson [2] on which this conclusion was first based, are set out below.

Consider a charge Q which occupies a spherical region within the cloud, its centre at height H above the ground.

The field at P (Fig. 14) is that due to an electric doublet of moment $2QH$, the opposite charge induced on the earth by Q being replaced by the image-charge $-Q$. This field is then $F = 2QH(H^2 + L^2)^{-3/2}$ and is directed vertically downwards if Q is a positive charge.

A lightning discharge involving Q may be of two kinds. If it is a discharge within the cloud, Q may most simply be considered to move vertically from a height H_2 to a height H_1, where it neutralises an opposite charge $-Q$. If it is a discharge to ground, Q disappears and F becomes zero. The net field-change produced by a cloud discharge is then

$$\Delta F_C = F_1 - F_2 = 2Q[H_1(H_1^2 + L^2)^{-3/2} - H_2(H_2^2 + L^2)^{-3/2}] \quad . \quad (3.1)$$

and that due to a discharge to ground is

$$\Delta F_G = O - F = -2QH(H^2 + L^2)^{-3/2} \quad . \quad (3.2)$$

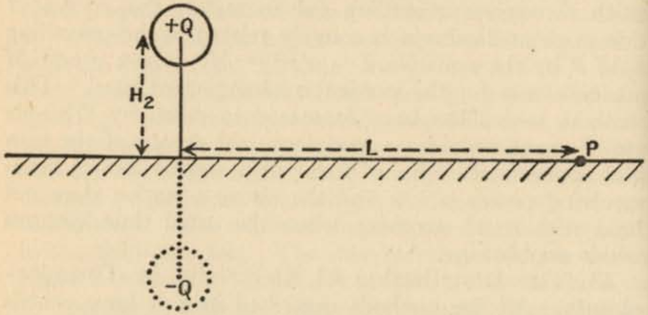

FIG. 14.—Thundercloud charge above the earth.

From observations of the sign of these field-changes one can infer the polarity of the cloud dipole responsible for them. If Q is a positive upper charge ($H_2 > H_1$) eqn. (3.1) shows that ΔF_C will be positive for all values of L less than a critical value L_0 and negative for all values of L greater than L_0. L_0 will be given by

$$H_1(H_1^2 + L_0^2)^{-3/2} = H_2(H_2^2 + L_0^2)^{-3/2}.$$

Again, if Q is a negative lower charge moving from height H to ground, eqn. (3.2) shows that ΔF_G should be positive at all distances.

Observations of ΔF_C and ΔF_G at various distances have verified these deductions and hence indicate that the majority of thunderclouds carry positive charges above and negative charges below. Table VI gives the results of observations of ΔF_G which show predominantly positive field-changes at all distances.

TABLE VI

SIGN OF FIELD-CHANGES DUE TO FLASHES TO GROUND AT ALL DISTANCES

Positive.	Negative.	Observer.	Place.
67	4	Schonland	Somerset East, S. Africa
267	16	Halliday	Johannesburg, S. Africa
77	13	Jensen	Nebraska, U.S.A.
411	33		

As concerns ΔF_C, eqn. (3.1) and (3.2) show that both cloud and ground flashes should produce positive field-changes when the storm is near but that the former should reverse to negative changes when the storm is at a distance greater than L_0. Since in storms in tropical and semi-tropical regions cloud discharges considerably outnumber ground discharges, we should expect to find in such storms a preponderance of negative field-changes at a distance and of positive ones when the cloud is near. That this is the case is shown by the data from South Africa in Table VII.

The South African observations in the Table offer strong evidence for the reversal effect. Those from Great Britain support them in showing a considerable preponderance of positive field-changes at small distances but in this case field-changes of either sign are about equal in number at distances exceeding 15 km. The reason for this is that in Britain cloud and ground discharges are approximately equally frequent whereas in South Africa the former considerably outnumber the latter.

Observations of actual zero values for ΔF_C at the reversal distance ($L = L_0$) are rare. In practice the flash does not usually take a vertical path between H_2 and H_1. For this reason and because H_2 and H_1 vary from one flash to another the concept of a reversal distance must be replaced by that of a reversal zone, in which small field-changes of either sign are equally probable. This zone may extend over a range of from 7 to 15 km. from the point of observation.[4]

TABLE VII

< 5	143	63	Wormell	England

Further strong evidence that the lower charge is usually a negative one has been given by direct observations of the polarity of lightning discharges to earthed metal structures (§ 41). These have been made in Europe, Russia, Japan and the United States and show that 90 per cent. or more of such flashes discharge negative electricity. The total number of direct observations available in 1941 was 2505 and 2422 indicated negative discharges.

In conformity with the general picture of the charge distribution outlined above, it is generally observed that the electric field from a nearby storm just before it discharges (the pre-discharge field) is negative, since the lower pole is nearer to the point of observation, while at a considerable distance it is found to be positive, the effect of the upper pole being then predominant. In these observations there is, however, a complicating factor of some interest. It is frequently observed that just before a very close discharge to ground the pre-discharge field becomes small and may even become positive.

This effect is explicable if there exists below the lower negative pole of the cloud an additional small " pocket " of positive charge either in the base of the cloud or in the air just below the base. Direct evidence for this pocket is discussed in the next section. Indirect evidence is afforded by the observation of Wormell [3] that there is a type of cloud (or air) discharge which reverses in sign at a much shorter distance than the normal and higher discharge between the main poles of the cloud and which is responsible for some of the apparently anomalous negative values of ΔF from near discharges quoted in Table VII. The type β leader process discussed in § 36 leads to the same conclusion.

All these deductions as to the distribution of charge in the thundercloud have been very beautifully confirmed and extended by the alti-electrograph balloon observations of Simpson, Scrase and Robinson.[6, 9] These have shown that in a balloon ascent near to or through the active centres of a thundercloud, the field is frequently positive on entering the cloud-base, after which it becomes negative for about 1 km., then positive for as much as 4 km. and thereafter it remains negative to the top of the cloud and beyond. The results from a typical sounding of this type, in which the width of the looped lines indicates the order of magnitude of the field and negative and positive fields are shown as open and hatched loops respectively, are given in Fig. 15 (*a*). The figure also shows the distribution of the three charges, *P*, *N* and *p* which were suggested to account for the observations. The values found for the heights of these charges, and so for the temperature levels at which they lie vary considerably from storm to storm. It is not possible to be certain what path the balloon has followed in its fairly slow flight through the cloud nor whether the charge distribution derived from the results is that existing at the moment a flash takes place, but typical values for large thunderclouds in England are *P*, 7 km. (– 27° C.), *N*, 2·5 km. (– 4° C.) and *p*, 1·5 km. (+ 2° C.).

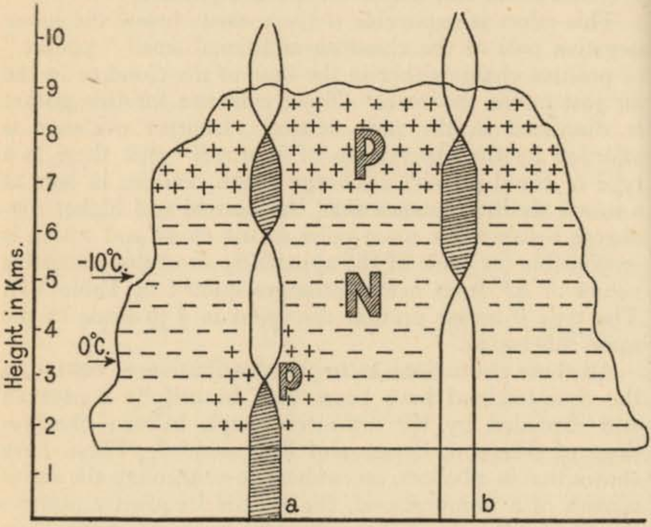

FIG. 15.—Typical alti-electrograph soundings (after Simpson, Scrase and Robinson)

The small *p* charge (which is called *Q* by Simpson, Scrase and Robinson) is not always observed, either because it is absent or because its small magnitude and dimensions cause the balloon to miss it. In such cases the record obtained is as in Fig. 15 (*b*).

Further confirmation of the general $P - N$ dipole distribution in thunderclouds has been obtained by Gish and Wait (§ 30) using the electric fluxmeter in aircraft flights above the tops of thunderclouds.

34. Magnitudes of the Electrical Quantities Involved in Thunderclouds. When the distance L is large compared with the heights H_1 and H_2 of the main P and N cloud-charges, eqn. (3.1) takes the form

$$\Delta F_C = 2Q(H_1 - H_2)/L^3$$

or

$$2Q(H_2 - H_1) = -\Delta F_C \times L^3 \quad . \quad . \quad (3{\cdot}3)$$

The quantity on the left is the difference between the electric moments of the thundercloud charges taking part in the discharge and is called the electric moment, M, of the discharge dipole. To determine it, the field-change due to a distant cloud flash and the horizontal distance L are required. The most frequent value of M determined in Great Britain[3] is 110 coulomb-km. though values as high as 1200 coulomb-km. have been observed. The average value for South Africa is 90 coulomb-km.[4]

Since $H_2 - H_1$ is approximately 2 km. the average quantity of electricity, Q, neutralised in a cloud discharge is about 20 coulombs. The range of variation of Q in individual discharges is from 2 to 200 coulombs if the vertical length of the discharge is supposed constant. If this length could be measured in every case, the variation would probably be much smaller.

The average electric moment of discharges to ground, which usually involve the lower negative pole only, is found to be of the same order as that of discharges within the cloud.

A single cloud-flash appears to discharge most of the section of the cloud which is producing lightning at the time. A fairly active thunderstorm produces one flash every 20 sec. To feed these flashes alone, it would have to separate out charges of opposite sign at an average rate of 1 coulomb/sec. and the generating mechanism would have to provide an average current of 1 amp. Reference has been made in § 32 to the rapid rate at which the initial regeneration of the field takes place after a flash. In the case of cloud discharges it is usually such as to be able to restore the whole field in about 5 sec. if it continued for that time. The exponential form of the recovery curves suggests that this initial rate of supply of charge remains constant but that an opposite neutralising effect occurs which tends to diminish the rate of increase of the charges and which is proportional to the quantity of charge present at any time.

That neutralising or dissipating effects of this nature exist below the cloud is shown by measurements of the mean current from positive point-discharge flowing upwards from the earth to the *N* charge (§ 29). This current is of the order of 2 amp. A similar dissipating current bringing negative charge down from the upper air to neutralise the *P* charge has been observed (§ 30). Its average value is about 1 amp. but it has been found on occasion to reach 6·5 amp.

The electrical energy generated by the cloud is thus only partially spent in the production of lightning discharges; just before a discharge most of the power of the generating mechanism is being used to overcome leakage effects opposing the building up of the main dipole. It may happen that the field, owing to this leakage load, never reaches the sparking value and the cloud, though electrified, does not produce lightning.

An estimate of the maximum potential reached by the two main cloud charges can be found from an argument given by C. T. R. Wilson.[10] Consider first the simple case of a charge Q contained within a sphere of radius R. The electric field at the surface is then given by $F = Q/R^2$. The maximum value of F for a discharge to occur is known from experiments by Macky on the behaviour of water drops in strong fields to be about 10,000 v./cm. or 33 e.s.u. This figure is one-third of that in normal air; the reduction is due to the fact that in strong electric fields a water-drop becomes unstable and pointed filaments are drawn out from opposite ends. For an average value of Q of 20 coulombs or 6×10^{10} e.s.u. the above equation gives $R = 427$ m. and the dimensions of the charged region are of the order of 1 km. The potential at the surface of the sphere is given by

$$V = Q/R = FR = 4{\cdot}2 \times 10^8 \text{ volts.}$$

If the radial electric force everywhere within the sphere were such as to produce sparking, the potential at the centre would be $2FR$ or about 8×10^8 v. Two such spheres carrying opposite charges would therefore be at a difference of potential of $1{\cdot}6 \times 10^9$ v. A similar result follows from the very different assumption that the two poles of the cloud are distributed in horizontal layers with a neutral region of thickness D, between them. If F is 10,000 v./cm. and D is 2 km., the difference of potential between them is 4×10^9 v.

Recent work on the manner of development of the lightning discharge (Chapter IV) suggests, however, that the average value of the field at the surfaces of the charged regions is considerably lower than 10,000 v./cm. Once a short leader streamer (§ 36) has been produced in a limited region where the field is momentarily 10,000 v./cm., its further development may be possible in fields which are only one-tenth as large. Actual measurements of fields inside thunderclouds by Ross Gunn[7] support this conclusion, for the highest "undistorted field" value reported was 1600 v./cm. just before the observing aircraft was struck by a discharge and the average maximum field for nine different thunderclouds was 1300 v./cm. If F is one-ninth of the value used above, the diameter of the spherical charged region ($2R$) becomes about 2·5 km., the potential reached before discharge $1{\cdot}4 \times 10^8$ v. and that between the poles $2{\cdot}8 \times 10^8$ v. These are likely to be lower limits for the potentials.

The disappearance of 20 coulombs in a lightning discharge is thus estimated to involve the dissipation of at least 6×10^{16} ergs or $1{\cdot}6 \times 10^9$ calories, most of which is converted into heat along the path of the lightning flash. A cloud giving one flash every 20 sec. is dissipating electrical energy in the form of lightning at an average continuous rate of at least 3×10^5 kw. To maintain in addition currents of the order of 2 amp. above and below it involves the provision of a further 6×10^5 kw.

CHAPTER IV

THE LIGHTNING DISCHARGE

35. General Features. The most frequent form of lightning is the *cloud discharge*. Though most cloud flashes are known from field-change records to be discharged between the main *P* and *N* charges of the cloud dipole (Fig. 15), there is evidence that others pass between the *N* charge and a lower positive charge, either the small *p* pocket of Fig. 15 (*N-p discharge*) or a positive space-charge in the air below the cloud (*air-discharge*).

A similar type of flash between the *P* charge and negative charge drawn down from the upper air to the top of the cloud or to the air immediately above it, would account for many cloud-flashes which are seen at night to be restricted to the cumulus heads of thunderclouds and the regions above them.

Most ground-discharges, as has been shown in § 33, remove negative charge from the *N* region. There is a good deal of evidence to show that they are usually triggered off by the strong field between the *N* and *p* charges or the positive space-charge in the air, thus extending an *N-p* or an air discharge all the way to the ground. The first strokes of such discharges thus bring to ground the residue of the negative charge left after the smaller and lower positive charge has been neutralised.

A general account of the various forms of the lightning discharge and their effects will be found in reference 1.

Many lightning flashes, both within the cloud and to ground, are observed to flicker. Early camera studies by Walter and others showed that this is due to the fact that the discharge consists of a number of separate components or strokes. Though the whole flash often occupies more than a second, the luminosity of the component strokes is generally over in a few milliseconds. After each stroke the ionisation along its channel, though much reduced by electron-attachment and by recombination and diffusion of the ions, usually persists in sufficient measure to provide the following stroke with a ready-made path which it follows. If, however, the time-interval is exceptionally long, the channel ionisation is too much weakened and the following stroke may take a different path.

The channel is often shifted several metres by the wind in the intervals between strokes ; the discontinuous nature of the discharge is then shown as *ribbon lightning*.

Observations with moving cameras show that the branching of the lightning discharge to ground is almost always confined to the first stroke of a series.

The maximum number of strokes so far observed from a single flash to ground is 42. The most frequent number is 3 or 4 and single-stroke discharges are quite common. The time-interval between strokes is variable, the most frequent value lying between 0·03 and 0·07 sec.

36. Luminous Streamer Processes in the Discharge. (*a*) *Experimental methods.* To investigate the nature of the luminous processes in the lightning discharge much use has been made of a method of high-speed photographic recording devised by Sir Charles Boys. If a camera is so constructed as to provide relative motion of lens and film, the recorded image of any series of luminous events in two-dimensional space will be distorted in such a way that later events are progressively displaced in position relative to earlier ones. Comparison of the distorted picture of a lightning discharge with one taken on a fixed camera would then show the order in which light was emitted at different parts of the channel. In practice, however, this is very difficult unless the distortion is large, because both fixed and moving cameras require an accurately placed reference line for the comparison. The difficulty is avoided in the Boys camera by the use of two lenses rotating in a circle ; these give two pictures with distortions in opposite directions and a reference line provided by a diameter of the circle. This principle has been used to follow the processes in the discharge with a time resolution of 1 microsec. Full details of the Boys camera and of later forms of camera which have been used by the writer and his associates in South Africa are given in references 1 and 2.

(*b*) *General results.*[1, 3] Each separate stroke of a discharge to ground has been found to be of a dual nature. A downward-moving luminous process, the *leader* streamer, is followed upon arrival near the surface of the ground by a much more rapid and intensely luminous main or *return* streamer which re-traverses the channel in the reverse direction. The leader to the first stroke is of a different nature to the leaders to subsequent strokes ; it takes about ten times as long to reach the ground and its luminosity is intermittent instead of continuous.

Fig. 16 (*b*) (after Schonland, Malan and Collens) illustrates these points in the case of a discharge of three strokes which has been photograped by a single-lens camera in which the lens has moved in a straight line from left to right. It is actually a picture in two dimensions of space and one of time since horizontal displacements with reference to the fixed picture (*a*) represent time as measured from the point P. These displacements are not shown on a uniform scale in the diagram. The Boys camera gives two simultaneous pictures from two lenses moving in opposite directions and thus avoids the use of a fixed picture.

The figure shows that the leader to the first stroke proceeds in a series of steps. Each of these is about 50 m. in length (range 10 to 206 m.) with fairly regular pauses (31 to 91 microsec.) between the steps. After each pause there is almost always a fresh direction of travel, and these changes in direction are responsible for the tortuous form of the lightning channel. The branches of the leader, which are usually found in the first stroke only, are similarly developed in steps and move outwards from the main channel. Each step is the bright tip of a long streamer stretching down from the cloud, the stem of which is faintly illuminated.

When the most advanced branch of the stepped leader system approaches within from 15 to 50 m. of the ground,

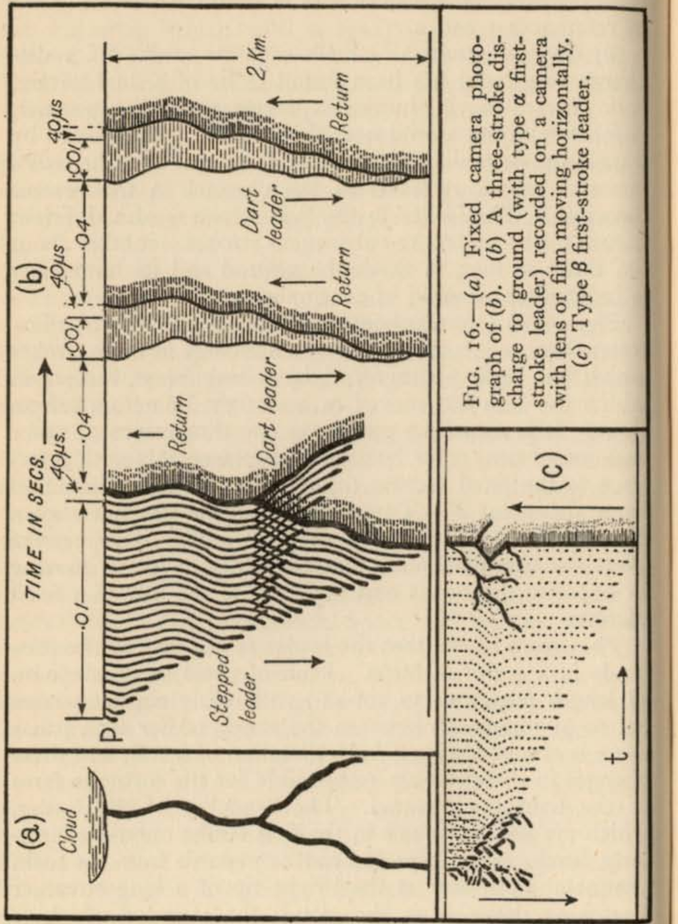

FIG. 16.—(*a*) Fixed camera photograph of (*b*). (*b*) A three-stroke discharge to ground (with type α first-stroke leader) recorded on a camera with lens or film moving horizontally. (*c*) Type β first-stroke leader.

the return streamer jumps the gap and passes rapidly back from ground to cloud, running outwards along each branch. This process takes microseconds to traverse parts of the channel originally created in milliseconds by the stepped leader.

Stepped leaders are of two types. In the type α leader (Fig. 16 (*b*)) the steps are short and are often difficult to photograph because they are not very bright. In the type β leader (Fig. 16 (*c*)) the upper part of the channel is formed by longer and brighter steps than the lower portion which has very weak type α steps. This difference is associated with extensive branching in the upper part of the channel. It suggests that there is a stronger electric field, due to positive space-charge in the air below the cloud, at the top of the leader path than later on. Electric field studies of the leader process show that although photographic records of events in the air below the cloud indicate that only 10 per cent. of leaders are of type β, this type is actually the most frequent one. The β stage in the leader is usually hidden within the cloud, the high field regions required to produce it presumably lying between the *N* and *p* charges of Fig. 15.

In the case of strokes subsequent to the first, the leader is not stepped but travels continuously to ground. As shown in the figure, it records as a continuous bright line followed (in the time dimension) by fainter illumination. This indicates that the leader takes the form of a fast-moving javelin, or dart, with a bright point about 40 m. long and a long, faintly-illuminated stem extending back to the cloud. For this reason it is termed a *dart* leader. The only exceptions to the continuous movement occur when an unusually long time-interval has elapsed since the preceding stroke ended. The dart leader is then much slower; frequently it shows the stepped method of progression over part of its length and takes a path different from that of its predecessors.

A typical first-stroke return streamer record is shown in Fig. 17. Times are shown in microseconds after the start at O.

The streamer covers the distance of about 2 km. between ground and cloud in 60 microsec. The figure shows that it continues to remove charge from the cloud for a further 600 microsec. The brightness and velocity of the streamer decrease as it travels upwards but are revived suddenly

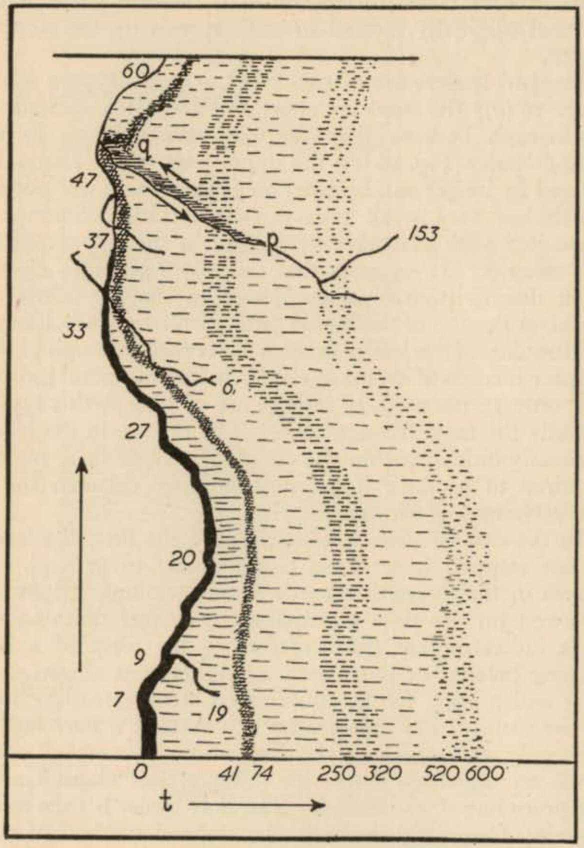

FIG. 17.—Return streamer time-table (Malan and Collens). (Times in μ-secs.)

as each of the branching points is reached, indicating, as has been shown by the detailed studies of Malan and Collens,[4] that the charge on a branch calls into existence a fresh flow of current from the ground. The current at the base of the channel is subject to violent fluctuations (*M* components) from these effects. Further fluctuations, (like the last two in Fig. 17), are produced by processes which are hidden in the cloud. In the case of subsequent strokes these latter fluctuations are the only ones observed because there are usually no branches to be traced by the return streamer.

The average velocities of the three processes which have been described, the dart, return and step streamers, are 2,000, 20,000 and more than 10,000 km./sec. respectively. Although individual steps are pushed forward at > 10,000 km./sec., the step-streamer process as a whole, as Fig. 16 shows, is slow, for its numerous pauses cause it to have an *effective* velocity which seldom exceeds 300 km./sec. and can fall as low as 100 km./sec.

In the case of very tall structures like the Empire State Building, 1250 ft. high, McEachron and Hagenguth[5] have shown that the lightning discharge frequently begins with an *upwardly* directed stepped leader which travels from ground to cloud and is not followed by a return process. The current continues to flow for some time in the channel thus formed, after which a normal downward dart leader, followed by an upward return streamer, creates the second and later strokes.

37. Electrostatic Field-changes associated with Lightning Processes. The processes described in § 36 give rise to electrical field-changes which are best studied by the amplifier-oscillograph method of § 32 (*d*) or the electric fluxmeter of § 17.

Fig. 18 (A) shows the general form of the field-changes produced by a ground discharge of three strokes when near (3-5 km.), but not directly over, the recording instrument.[6, 7] Fig. 18 (B) shows the form taken by the same field-changes when the flash is fairly distant (12-20 km.). In this case, as described in § 40, induction

CHRIST'S COLLEGE

and radiation field-changes would be superimposed on the electrostatic field record but for the sake of clarity they have been omitted from Fig. 18 (B).

The manner in which various sections of the field-change record have been identified with the various streamer-processes observed with the Boys camera is shown in the figure. The *l* portions of the record correspond to the downward movement of leader streamers and the two *r* portions, r_b and r_c, with the upward return streamer. The remaining *j* portion corresponds to a streamer process which cannot be photographed since it takes place within the cloud. From a detailed study of records of this kind the following conclusions can be drawn :

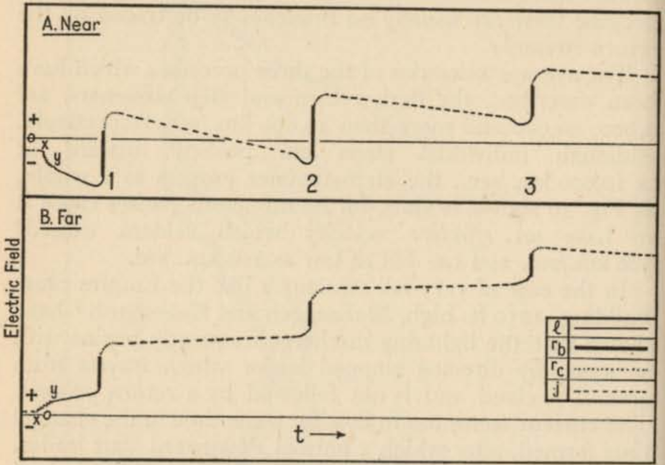

FIG. 18.—Electrostatic field-changes due to a discharge to ground (Schonland and Malan).

(1) *Leader* (*l*) *field-changes.* These, which produce hook-shaped negative changes when nearby and parabolic positive changes when at a distance, indicate clearly the lowering of negative charge towards the ground by the leader streamers. Since they remove charge from an initial height, H_2, to a lower effective height, H_1 (§ 33, eqn. 3.1) when the charge is distributed along the channel, their net field-changes reverse in sign with distance.

The leader to the first stroke in Fig. 18 shows a field-change which has a much larger slope over the first section *xy* than later. This is because it is a type β leader (§ 36 *b*), and lowers charge more rapidly in its initial than in its final stage.

As Fig. 18 shows, dart leaders to subsequent strokes occupy a much shorter time than the first stepped leader but show a similar form of field-change.

It is of some importance that the durations of leader field-changes are often much longer than the durations of the corresponding leader processes recorded by cameras operating at the same time. For this implies that a considerable length of the leader channel, sometimes of the same order as the visible length below the cloud, is hidden inside it and that the *N* charge creating the leader is at a considerable height.

(2) *Return streamer* (r_b *and* r_c) *field-changes.* Since these involve the removal to ground of the negative charge on the leader (r_b) and remaining in the cloud (r_c) their field-changes are positive at all distances. The rapid r_b change occupies a time of the order of 50 microsec. and has a complex fine structure which is not shown in Fig. 18. The slower r_c change, which occupies 1 or 2 millisec., is considered to be due not only to the final mopping-up of the charge remaining in the region which produced the leader, but also to an upward flow of positive charge induced on the top of the channel by *N* regions as yet untapped by the discharge.

(3) *Junction* (*j*) *field-changes.* These changes occupy the intervals between strokes. Since they are negative when near and positive when far, they must be created by slow movements of charge within the cloud, in which positive charge moves upwards or negative charge moves downwards. There is some evidence [7] that in most cases they are due to the upward movement of positive streamers

from the top of the channel to new regions of negative charge, which they render conducting.

(4) *The mechanism responsible for successive strokes.* It has been shown by Malan and the writer[7] that a number of lines of evidence leads to the conclusion that each stroke of a discharge to ground comes from an *N* region which is higher than that producing its predecessor. From this and other information it is deduced that the *N* regions creating a discharge of many strokes are not haphazardly distributed within the cloud but form a single and approximately vertical column which is intermittently discharged and which extends upwards to considerable heights. A ground flash of many strokes may come from a column 6 km. long. These authors have shown that the pauses between strokes represent the time required for the junction-streamer process to move upwards and render the next section of the charged column sufficiently conducting for it to discharge down the channel as a leader.

38. The Mechanism of Streamer Development.[8] It is known from laboratory studies of gas-discharge processes that an electrical streamer possesses a conducting stem filled with ions and electrons and that the motion of these charged particles in the field prevailing inside the stem constitutes a current which keeps the streamer surface, and its tip in particular, supplied with charge as it moves forward. For forward movement the electric field at the tip must be sufficiently great to cause free electrons in the air in front of the advancing streamer, some of which are created photoelectrically by ultraviolet light from the streamer itself, to ionise by collision. This ionisation is cumulative and leads to the production of electron avalanches which extend the streamer tip.

The streamers give out light at and behind their tips because excitation as well as ionisation occurs in the strong field region. Since the excited atoms and molecules return a short time later to their ground-states, and since the tip moves forward during this interval, the region of intense luminosity extends backwards for a limited distance behind the tip.

In the case of the dart leader, the negatively charged streamer is guided along a pre-existing channel because ionisation created by previous strokes exists in front of the advancing tip. It can be shown that the velocity attained by the streamer in this case should be proportional to the cube root of the pre-existing electron density, n, in front of it.[8] When the interval between strokes is short, n is large and high dart-leader velocities are possible, but when the interval is long and n has been reduced by electron attachment to atoms and molecules and by diffusion processes, the dart leader velocity is low.

The fast return-streamer also travels along a previously ionised channel, more heavily ionised and fresher than that available to the dart leader. In this case, however, as was first shown by Simpson, the tip of the streamer is positively charged and the electron avalanches in front of it move inwards in a strongly converging field. These factors account for the high velocity of the return streamer.

The stepped leader, which is the first of all the discharge processes, appears from the photographic records to involve advance into virgin air and to follow no pre-existing trail of ionisation. Its slow effective velocity, which is of the same order as the minimum velocity at which an electron can ionise by collision, coupled with the very high velocity of the step streamers themselves suggests, however, that it too follows an ionised path prepared by an unrecorded *pilot* streamer, or a cone of such streamers, which precedes it. On this view the steps are secondary effects superimposed upon the pilot streamer and catching up at intervals with it.

Such pilot streamers would be controlled in direction by purely local variations in the electric field in front of their tips and their paths will be tortuous and branching, especially if the air contains concentrations of positive ion space-charge.

A fuller discussion of these streamers and of the unsettled question of the mechanism responsible for the fairly regular pauses observed in the stepped process will be found in references 9, 10 and 11. It is generally agreed that these pauses owe their origin to a property of the streamer itself[8] and not to any intermittent feature in the discharge from the cloud but whether this property involves a periodic transition from a "glow" to an "arc" form of streamer or is simply due to the streamer overreaching itself and requiring a pause to renew the field-strength and the conductivity of its stem is not yet certain.

39. Discharges which do not Pass to Ground. Discharges which do not reach the ground, whether they are air-discharges or take place entirely within the cloud are found to be of the leader type, without the usual return process. Air discharges when photographed show complex branched type β step-leader streamers with dart leaders superimposed upon them. They travel towards local concentrations of positive space-charge below the cloud and weak "recoil" streamers moving back from such concentrations have been observed. An example of recoil is shown along p, q in Fig. 17.

The study of discharges which are entirely within the cloud has so far been possible by field-change methods only. These show that cloud discharges are of the same character as air discharges and can occupy times of the order of milliseconds.

40. Induction and Radiation Field-changes. The form of the electrostatic field-changes associated with lightning discharge processes has already been described. The complete electric field from a small dipole of moment M is actually the sum of the components represented by

$$E = M/r^3 + (dM/dt)/cr^2 + (d^2M/dt^2)/c^2r,$$

expressed in e.s.u. where c is the velocity of light and r the radius vector to the centre of the dipole. The first term corresponds with eqn. (3.1) for the electrostatic field, the second is the induction or magnetic term and the third the well-known expression for radiation from a Herzian dipole. Within 10 km. of a lightning flash the first term is much larger than the other two and the field-changes caused by lightning produce mainly electrostatic effects. At 25 km., however, the last term shows up strongly and at 50 km. and beyond, it is predominant.

The radiation field is proportional to d^2M/dt^2 and so to the rate of change of the current in the portion of the discharge concerned at time $t - r/c$. Radiation effects from lightning are therefore most prominently associated with processes which involve the rapid starting and stopping of streamers carrying large currents. These are (*a*) the stepped processes found in first stroke leaders and in cloud and air discharges and (*b*) the return processes in each stroke.

The radiation effects of these processes are found to constitute the majority of atmospheric (static) disturbances on the longer wavelengths used in radio communication and can be observed more than 4000 miles away from the parent discharge. They have been of practical value in the location of thunderstorms for meteorological purposes (sferics) and the manner in which they are modified by successive reflections from the ionosphere has been used to give information about the height and nature of its lower D layer.[1, 12]

41. Currents and Current Variations. Much work has been done to determine directly the magnitudes of lightning currents to ground and their time-variations.[9, 10] One instrument used for determining peak currents through elevated conductors and towers struck by lightning is a simple recording voltmeter, known as a Klydonograph, placed across one of a string of insulators acting as a potential divider and connected between the conductor and the earth. This device makes use of the fact that the diameter of the "Lichtenberg" figure produced around a positive point resting on a flat photographic film backed by an earthed plate is proportional over a certain range (up to 25,000 v.) to the potential difference between point and plate. To record discharges of both polarities two instruments, oppositely connected, are necessary.

The Klydonograph method requires a knowledge of the surge impedance between the conductor and the earth and this is not always easy to determine. More use has recently been made of "magnetic links," two or three bundles of short unmagnetised steel strips of high retentivity which are mounted at different known distances from the conductor. The peak currents passing in the discharge can then be found from the remanent magnetism in the links, calibration being effected with known currents.

In a development of this device called the Fulchronograph (Wagner and McCann)[14] the links are carried on an aluminium wheel which rotates between coils through which the lightning discharge passes. The remanent magnetism of successive links then gives the time variation of the current.

The time variation has also been determined by shunting special types of oscillograph across resistances of high current capacity. The data are, however, as yet insufficient for a generalised statement of the manner in which the current in a discharge varies with time in the successive strokes of a discharge. In first strokes it rises to a peak of average value 20,000 amp. (maximum observed value 250,000 amp.) in from 1 to 20 microsec., with a most frequent " time to peak " of 2 microsec. Its manner of decay is variable but it is usually stated to fall to half its peak value in about 24 microsec. (range 7 to 115 microsec.).

Continuing currents of considerable magnitude and of long duration have been found by McEachron[13] to follow strokes to the Empire State Building but in discharges to lower structures the current is usually found to have fallen to very low values ($< 0{\cdot}1$ amp.) a few milliseconds after the start of the return portion of the stroke.[14]

The quantities of electricity found by integrating the current-time curves of direct discharges are of the same order of magnitude (average 30 coulombs, maximum 164 coulombs) as those determined by the method of C. T. R. Wilson (§ 34).

CHAPTER V

CHARGE GENERATION IN CLOUDS

42. Introduction. Many suggestions have been made as to the manner in which electric fields can be built up in clouds. Some of these have had to be discarded as facts on which to test them have accumulated. Most of the mechanisms left in the field may well be in operation at the same time and it is not easy to decide which are predominant in creating the electrification of thunderstorms.

An acceptable theory must (*a*) offer an explanation of polarity of the main *P-N* dipole; (*b*) give *P* and *N* charges each of about 30 coulombs under reasonable conditions of temperature, water-content and updraught; (*c*) operate at a temperature at least as low as − 10° C., and (*d*) be shown experimentally to work. Subsidiary mechanisms may be necessary to account for the lower *p* charge and for observations to be described in § 45 on the relation of the charge on thunderstorm rain to the prevailing field.

Of the theories which have been rejected because they did not meet all these conditions the best-known is that of Simpson, which proposed to account for the main electrification of the cloud by the Lenard effect, the breaking-up of water-drops in ascending air-currents. This mechanism, which left the larger fragments with a positive charge can satisfy neither the temperature condition (*c*) above nor condition (*a*), since it requires the lower portion of the cloud to be positively charged. It may, however, as Simpson and Scrase have suggested, be responsible for the small *p* charge of Fig. 15.

43. The Separation of the Opposite Charges once they are Formed. All the mechanisms which are at present under consideration satisfy condition (*a*) because they all suggest two entirely different types of carrier for positive and for negative charge and because all give a

negative charge to the heavier of the two types. Polarisation of the cloud in the requisite direction then follows automatically by the action of gravity in pulling the negative charges down (Fig. 19). When an updraught in the cloud is capable of supporting or even of driving upwards the heavier negative group of carriers (raindrops or snow or large ice-particles) the lighter ones (droplets or ice-fragments) are driven upwards still faster, so that the relative velocity of separation of the two groups is the same as if no updraught were present.

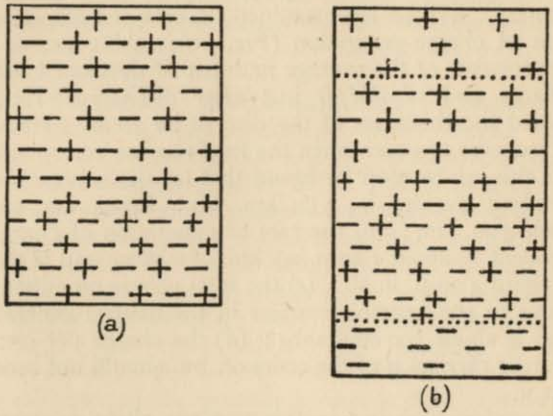

FIG. 19.—Gravitational separation of opposite charges (C. T. R. Wilson).

The shape of the field-changes immediately after a cloud-discharge (§ 32) suggests that the process of separation of the oppositely-charged carriers is one involving initially free fall under gravity and that this free fall is progressively retarded and finally reduced to nearly zero by the attractive forces between the separating charges. The rate of fall of the heavier carriers in this final stage must be considered just sufficient to maintain the charges constant in the face of dissipation currents within the cloud and directed to it from outside. Ultimately the field between the separated charges may become strong enough for a discharge to pass. If the charges are equal, this leaves the cloud in its initial state and the larger carriers in the neutral region of Fig. 19 once more separate out under the action of gravity. The relative velocity of separation has been taken by C. T. R. Wilson[1] to be of the order of 6 m./sec., the terminal velocity of a water-drop 0·15 cm. in radius. Relative to such a drop, the much slower positive droplets may be considered as stationary. Wilson has examined the case of a disc-shaped region of charge-generation (Fig. 19) making use of his measurements of the average moment M developed before discharge and of dM/dt just after discharge. He has assumed the thickness of the disc to be about 1 km. and the discharge to occur when the field reaches 10,000 v./cm. From this information he found that (*a*) the volume of the generating region is 4 cu. km. and hence its cross-section 4 sq. km.; (*b*) the rate of generation of charge is equivalent to about 1 amp./sq. km. of surface and is therefore about 4 amp. in all; (*c*) the total charge on either the positive or the negative carriers in the neutral generating region is about 500 coulombs; (*d*) the charge per c.c. on the larger carriers is of the order of, but should not exceed, 30 e.s.u.

The values deduced in this way are all in conformity with what is known of the quantities concerned. They are not seriously changed if modifications are made in the postulates to bring these into closer agreement with more recent information (thickness 3 km., breakdown field 1000-10,000 v./cm.).

A different type of cloud polarisation by gravity has been discussed by Frenkel in connection with fog-like clouds of small droplets. These are considered by him to be capable of capturing negative ions from the air (§ 44 (*b*)) which is then left with an excess positive charge.[2] The charged droplets are not held up completely by the internal field but drift slowly downwards at such a rate that the polarisation charge developed per unit area is equal to the charge neutralised by the internal conduction or dissipation current in the same time. The internal field, E_s, in this "stationary" condition is related to the equilibrium field, E_q in which the drops are fully supported, by the equation $E_s/E_q = \Delta/\lambda$ where λ is the ionic conductivity of the air and Δ is the much smaller contribution to the conductivity provided by the droplets. E_s is found to be of the order of 100 v./cm., a hundred times less than Eq. In clouds where the water content is greater, the positive ions will attach themselves to larger particles and the development of polarisation in the thundercloud then appears to become the same as that considered by C. T. R. Wilson.

44. Suggested Mechanisms of Thundercloud Electrification. (*a*) *Mechanisms which depend on the selective capture of negative ions by the larger carriers.* A mechanism suggested by C. T. R. Wilson depends upon the selective capture of negative ions from the air by large falling water-drops or ice-particles, the residual excess positive charge in the air being absorbed by very small droplets or ice-fragments in the upper part of the cloud.

For the mechanism to work, the ions concerned must be large ones (§ 1). Since their mobility is about 0·0003 cm./sec., the velocity with which they move under the influence of the prevailing electric field is much less than the velocity of fall of the larger carriers.

Consider a large drop or ice-particle inside a cloud in which a downwardly-directed field already exists. Owing to this field the drop will have a negative induced charge on its upper surface and a positive charge below (Fig. 20). In the case of an ice-particle, Chalmers has shown that dielectric polarisation will produce a similar distribution of charge.[3] As these larger carriers move downwards, they will approach positive ions moving down more slowly and negative ions moving up; encounters with other drops or ice-particles are considered to be relatively rare. The drops will behave differently in encounters with the two ion-streams. At the under-surface of a drop the negative ions will be attracted and the positive ions repelled and the former, if within a suitable distance, will be captured, giving the drop a net negative charge. The negatively-charged upper surface of the drop does not reverse the process, because here it is receding from the ion-streams and positive ions have been repelled away from the drop in the course of their passage past it. Innumerable episodes of this kind can cause the drop to acquire a considerable net negative charge, without appreciably altering the chance of further captures. A water-drop 1 mm. in radius, falling in a field of 10,000 v./cm. carries at each end an induced charge of 0·25 e.s.u. If it has collected a net negative charge equivalent to the very reasonable value of 12 e.s.u./c.c., the increase in the upper negative charge and the decrease in the lower positive charge will be 10 per cent. only. Whipple and Chalmers have shown that the maximum charge which can be collected in this way if ions of both signs are in equal concentrations is $-0\cdot52Fr^2$ when F is the field-strength and r is the radius of the drop. This gives 40 e.s.u./c.c. for the case just considered. If negative ions only are present the maximum charge collected is $-3Fr^2$, six times as great.

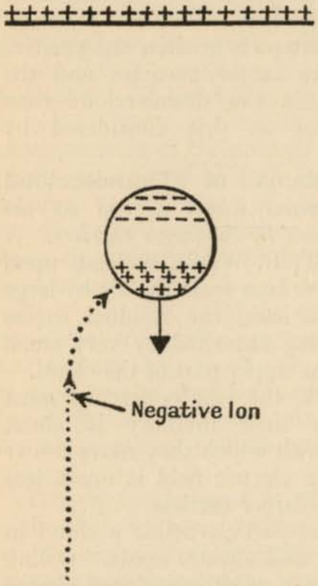

FIG. 20.—Capture of slow negative ions by large falling drops.

The tiny droplets and ice and snow particles, which fall relative to the air with a velocity of the same order as that of the ion-streams, will be unable to exercise the selective action described. They will therefore absorb a net positive charge, the complement of the negative charge collected by the larger carriers.

Wilson's mechanism operates in such a way as to enhance enormously a pre-existing field. This could be the normal field of fine weather or a field produced initially by one of the other mechanisms to be described. The Wilson process has been shown by Gott to work under laboratory conditions but it is not generally agreed that it is the chief agency in building up the fields of thunderclouds. One criticism which has been raised against it is that the concentration of large ions necessary for it to be effective is not likely to be present until the electric field is very strong.

The theory of Frenkel[5] is based upon a selective adsorption of small negative ions by water-drops or wet ice-crystals. Owing to the polar character of the water molecule, the skin of such carriers is considered to consist of an electrical double-layer with positive poles outwards. This tends to capture negative ions from the air until a difference of potential v_0 is created between the drop and the cloud of positive ions which surround it. The equilibrium negative charge acquired in this way is v_0r where r is the radius of the drop and v_0 is 0·25 v. This mechanism gives a considerable negative charge density to small drops but is not very effective in the case of large ones ($r = 0\cdot1$ cm., charge density 0·02 e.s.u./c.c.) nor does it give very large fields. To carry it further, Frenkel considers that adjacent downward-moving droplets coalesce into larger drops as a result of hydrodynamical forces between them. These larger drops in their downward flight sweep up and collect the charge from slower-moving droplets, obtaining in this way a charge which varies as r^3 and creating much larger fields. The theory does not appear to have been tested experimentally.

(*b*) *Mechanisms which depend upon electrification as a result of change of state.* In its earliest stage of development the cumulonimbus cloud consists almost entirely of droplets of water. Some of the droplets in the portion of the cloud above the freezing level remain unchanged in state and supercooled. As the cloud top rises, an increasing proportion of these droplets are converted into ice-particles, either directly or by the action of special "sublimation-nuclei". The effectiveness of these processes increases with decreasing temperature and hence with increasing height. Ice-particles formed in this way grow very rapidly at the expense of surrounding supercooled drops if the temperature is low. As these grow in size they fall and the mature thundercloud contains a complicated mixture of hard and soft hail, snow particles, rime-covered ice (graupel) and water drops. All these hydrometeors are in various stages of growth, or of disappearance, depending upon the temperature-levels to which they have risen or fallen and all of them are constantly colliding and coalescing with one another. The changes of state, and the collision and coalescence processes thus involved, offer a variety of opportunities for the generation of electric charge and a number of possible mechanisms have been based upon them, most of which have been tested experimentally. These are listed in Table VIII below.

Mechanism No. 7 is not one of change of state but is included in the Table because it involves ice; experimental test of it has so far yielded conflicting results. Mechanism No. 6 would not create a dipole of the correct polarity and could only operate in the lower levels of the cloud where like the Simpson breaking-drop mechanism, it may contribute to the formation of the lower *p* charge and the strengthening of the *N* charge above it (Fig. 15). Experiments by Kramer indicate that mechanisms Nos. 2 and 3 of Findeisen must be regarded as of minor significance compared with No. 1.

The remaining mechanisms, Nos. 1, 4 and 5, are all based upon electrification resulting from the freezing of supercooled drops, either directly (5) or by contact with falling ice-pellets (1 and 4). If one or other of them is responsible for the formation of the main cloud dipole, the first occurrence of lightning should be closely related to the first development of the ice-phase in the cloud. This in turn is bound up with the height and so with the temperature-level to which supercooled water-drops are raised by the updraught within the cloud.

TABLE VIII

	Proposer.	Charge Carriers.		Generating Process.	Sign of Charge on Heavy Carrier.	Remarks.
		Heavy.	Light.			
1	Findeisen and Kramer	Large rime-coated ice-particles	Small ditto	Coalescence of super-cooled drops with ice to form rime	−	Small rime fragments +vely charged
2	Findeisen	Ice	Ice-splinters	Growth of ice by sublimation from drops	+	Found experimentally to be of minor significance (Kramer)
3	Findeisen	Ice	Ice-splinters	Evaporation of ice	+	As for (2) above
4	Workman and Reynolds	Ice	Fragments of super-cooled drops	Glaze-ice formation on hail	−	Effectiveness increased by traces of $CaH_2(CO_3)_2$ in air
5	Chalmers	Ice	Water-drops	Sudden freezing of super-cooled drops	− ?	Not tested experimentally
6	Dinger and Ross Gunn	Water	?	Melting of ice at low levels	+	Presence of dissolved gases necessary before freezing if effect is to be appreciable.
7	Simpson and Scrase	Ice	?	Frictional electrification by collision	−	Inferred from Antarctic blizzard observations

Evidence as to the height of the larger droplets within the cloud at various stages has recently been made available by microwave radar studies of the so-called " cloud echo ". These suggest that full-scale electrification leading to fields sufficiently great to produce lightning does not occur until the supercooled droplets have been raised to a temperature level, variously given as between − 28° C. and − 40° C., where ice-crystal formation on an appreciable scale can occur.

These observations, together with the conclusions of Malan and the author (§ 37 (4)) that the *N* charge occupies a column of considerable vertical extent, whose top reaches to very low temperature-levels, make it probable that the main dipole electrification of the thundercloud is initiated as a consequence of freezing processes of one kind or another as soon as the ice-phase forms from super-cooled drops. The larger carriers of charge will then fall downwards and build up a field which may of itself be sufficient to cause spark break-down or may have to be enhanced by the selective charging mechanism of C. T. R. Wilson. Another method of enhancement, by droplets bouncing off melting hail in the lower portion of the cloud, has been discussed by Workman and Reynolds.[6]

45. The Charge on Rain from Electrified Clouds.

Although the predominant sign of the electric field below a thundercloud is negative (§ 33) it has long been known that the charge on the rain from it is mainly positive in sign. This can be qualitatively explained by C. T. R. Wilson's selective ion-capture mechanism (§ 44 (*a*)), which would operate as in Fig. 20 with all the signs in the diagram reversed and might be expected to be very effective since point-discharge at the ground creates an abundance of positive ions most of which will be converted by capture-nuclei of various kinds into heavy ions during their passage upwards to the cloud.

Simpson,[6] in an important series of observations made at Kew, has compared the current, *i*, carried down by rain to a square centimetre of the ground with simultaneous records of the rate of rainfall, *R*, and of the point-discharge current, *I*, from an elevated point. For potential gradients exceeding 2000 v./m. he finds the relation $i \propto -I \times R^{0\cdot 57}$ from which it is clear that (i) the sign of the charge on the rain in these fields is always opposite to that of the prevailing field (mirror-image effect); (ii) with a given rate of rainfall the rain-current is directly proportional to the point-discharge current, and (iii) with a constant point-discharge current the rain-current varies with the rate of rainfall, increasing or decreasing approximately as $\sqrt{R}$.

It is clear from these results that the rain derives its charge from point-discharge ions. Ultimately, in very heavy rain, all the point-discharge ions are swept up and brought back again to earth, the rain current being found equal to the estimated point-discharge current per square centimetre of the ground. Whether the Wilson mechanism alone can account quantitatively for these results is still under discussion; it is not impossible that more than one process is at work in charging the falling drops. The rain current by itself gives a statistical mean for the charge on the drops and there is evidence that individual drops can carry charges of opposite sign.

In light steady rain and in some showers, the electric field at the ground is found by Simpson to be generally negative and as high as − 1000 v./m. When it is positive it seldom exceeds the fine weather gradient of about + 400 v./m. Such rain is found to be positively charged, the charge on it being directly proportional to the departure of the field from its fine weather value. No explanation of this effect has as yet been suggested.

Electrical processes occurring in the atmosphere couple the atmosphere and ionosphere, because both DC and AC effects operate at the speed of light. The electrostatic and electromagnetic field changes in global electric circuit arise from thunderstorm, lightning discharges, and optical emissions in the mesosphere. The precipitation of magnetospheric electrons affects higher latitudes. The radioactive elements emitted during the earthquakes affect electron density and conductivity in the lower atmosphere. In the present paper, we have briefly reviewed our present understanding of how these events play a key role in energy transfer from the lower atmosphere to the ionosphere, which ultimately results in the Earth's atmosphere-ionosphere coupling.

1. Introduction

The atmosphere of the Earth is a layer of gases surrounding the Earth that is retained by Earth's gravity. The atmosphere protects life on the Earth by absorbing the ultraviolet solar radiation, warming the surface through heat retention (greenhouse effect), and reducing temperature extremes between day and night. Based on temperature distribution, atmosphere is divided into the troposphere, stratosphere, mesosphere, and thermosphere. The temperature in the thermosphere remains almost constant (Figure 1) [1]. The stratosphere and mesosphere regions are also grouped as the middle atmosphere. The region above the middle atmosphere is called the upper atmosphere where solar radiation and other sources ionize the neutral constituents forming plasma of ions and electrons. The region extending from the mesosphere to the thermosphere is called ionosphere where plasma dynamics is controlled by the collisions between the ionized particles and neutrals as well as between the ionized particles themselves. The region above the ionosphere is known as the magnetosphere. In this region, charged particles dynamics is controlled by the Earth's magnetic field because the density collision frequency is very low. There is no sharp boundary between the upper ionosphere and the lower magnetosphere region.

The ionosphere system is mainly controlled by various external sources of forcing and number of mechanisms operative in the system to convert, transport, and redistribute the input energy. Solar extreme ultraviolet (EUV) radiation and particle energy from the sun in the form of precipitating solar wind plasma energetic particle influence from the above, while tides, planetary waves, gravity waves, electromagnetic waves in wide frequency range, turbulence, convection, and so forth from the below. Even processes taking place below/on/above the surface of the Earth also affect the ionosphere and its processes. In fact, lower atmosphere/middle atmosphere/upper atmosphere (ionosphere)/magnetosphere acts as a multi-coupled system. The coupling occurs mainly through the dynamical, chemical, and electrical processes.

The ionosphere reacts to various phenomena such as lightening discharges, functioning of high-power transmitters, high-power explosion, earthquakes, volcano eruptions, and typhoons through a chain of interconnected processes in the lithosphere-atmosphere-ionosphere interaction system. Thunderstorms play a major role in transferring energy from the atmosphere to the ionosphere [3] and in establishing

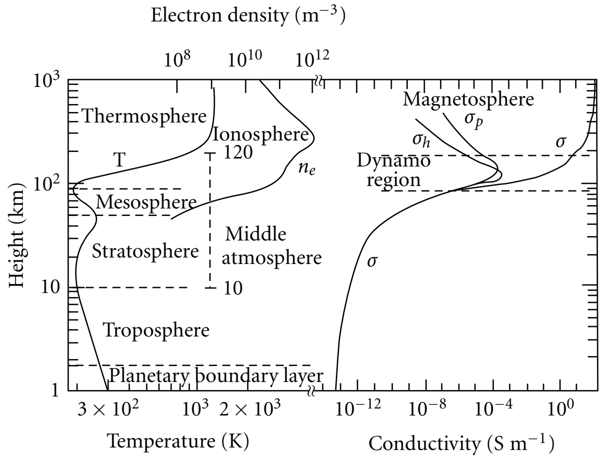

Figure 1: Variation of temperature, electron density and electrical conductivity of various atmospheric layers, after [1].

electrical coupling between atmosphere and ionosphere through the global electric circuit (GEC). The Earth's surface has a net negative charge, and there is an equal and opposite positive charge distributed throughout the atmosphere above the surface. The electrical structures of the lower atmosphere, GEC, and conductivity profile shown in Figure 1 are deeply influenced by cosmic ray flux [4], high-power transmitted waves [5–7], and earthquakes [8]. Lightening-generated whistler mode waves scatter radiation belt trapped electrons which precipitate into the lower ionosphere and result into the additional ionization and formation of ionospheric inhomogeneities [9, 10]. The powerful high-frequency transmitted waves produce ionospheric heating which, in turn, causes generation of ultra-low-frequency (ULF) and extremely low-frequency (ELF) waves [11], the formation of very low-frequency (VLF) ducts and other types of inhomogeneities [12, 13], the acceleration of ions, and the excitation of atmospheric emissions in different spectral bands [14]. The effects of these processes on the GEC (including the ionosphere) are not yet fully understood.

The convective activity in thunderstorms produces gravity waves which propagate to the lower ionosphere and deposit energy and momentum through the process of breaking and absorption and may help in the initiation of sprites and other transient luminous events (TLEs) [15–17]. The converse problem is the generation of acoustic gravity waves by sprites and other TLEs. The thermal energy deposited in the neutral atmosphere within a sprite volume ($\sim 10^4$ km^3) during short (<1 ms) duration may produce an impulsive pressure pulse that propagates laterally outward as an acoustic/gravity wave [18]. The energy deposited by a large sprite could be as large as ~1 GJ [19]. The acoustic gravity wave causes spatial and temporal modulation of plasma density and electric conductivity in the ionospheric E layer. The associated wave instability causes generation of related field-aligned currents and plasma density irregularities in the upper ionosphere [20]. The satellite observations anomalous DC electric field, ULF magnetic pulsations, small scale plasma inhomogeneities, and correlated ELF emissions [21] may be considered as experimental evidence for these processes. However, the full knowledge of the interconnection between gravity waves and TLEs remains unresolved.

The purpose of this paper is to review briefly the present understanding of the link between most of the processes operative in the lower atmosphere and their electrodynamic coupling with the ionosphere. After this introduction, Section 2 deals with a more detailed description of physics of the atmosphere-ionosphere coupling. Various coupling processes including AC and DC phenomena are discussed in Section 3. Brief summary is given in Section 4 with some discussions.

2. Physics of Earth's Atmosphere-Ionosphere (AI) Coupling

Thunderstorms and lightning discharges are the main sources of electromagnetic and electrostatic energy in the Earth's atmosphere. Electrostatics involves the buildup of charge on the surface of objects due to contact with other surfaces. Although charge exchange happens whenever any two charged surfaces contact and separate, the effects of charge exchange are usually only noticed when at least one of the surfaces has high resistance to electrical flow. In thunderstorms, a rapid vertical rearrangement of deep air layers takes place. Large processes promote, shape vertical and horizontal air motions, and processes within storms control the development of rain and strong local winds. Vigorous vertical air currents and thunderstorms are a consequence of excessive warmth and moisture at low altitudes.

Thunderstorm consists of a cluster of clouds. Electrical charges generate and separate during the developmental stage of thunderstorm and are neutralized during lightning discharges. Numerous processes operating within the environment of a mature convective cloud with varying effectiveness and time dependencies affect cloud electrification [22, 23]. The charging of thunderstorms can be discussed as inductive charging or noninductive charging. An inductive process requires preexisting electric fields to induce charges on a particle so that when it rebounds from another particle, charge is separated and the field is enhanced. In the atmosphere, the fair-weather electric field resulting from positive charges in the atmosphere and negative charges on the ground could be considered as the preexisting field. However, there are experimental results from airborne instruments which require some other processes of charging [22]. Noninductive processes are independent of the presence of an external electric field. In an ordinary thundercloud, the smaller ice crystals are charged positively and move upward, whereas larger graupel particles charged negatively descend relative to the smaller particles under the action of gravity. This is the normal situation, depending on the prevailing conditions of temperature, liquid water content, and mixing in the thunderstorm. Situation in thunderstorm is quite variant, and charging process may not remain as discussed above [24]. To better understand these phenomena, further investigations

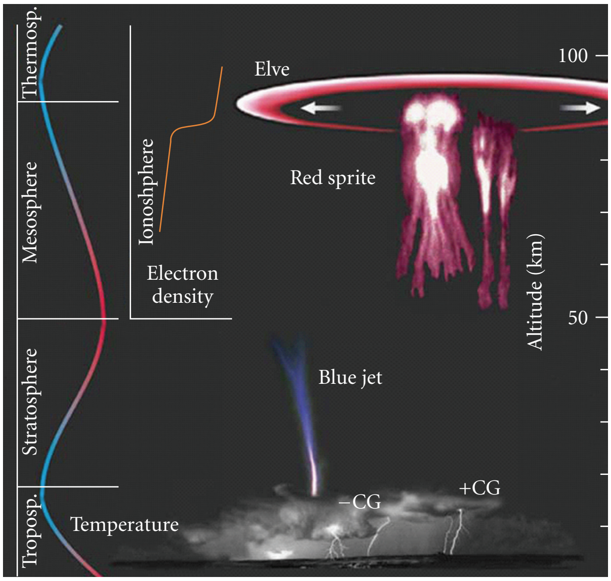

Figure 2: Depiction of various optical events in the atmosphere and the altitude at which they occur, credit [2].

involving both precise measurements of time development of electric field inside the cloud and simulations are required.

The charge buildup during the active period of a thunderstorm ultimately results into lightning discharge either through the processes of dielectric breakdown or runaway breakdown [29–32]. The electric field computation favours runaway breakdown mechanism [33]. However, discharge processes are not fully understood, and further observations and works are required. Lightning discharge creates charge imbalance in the cloud/thunderstorm, and as a result upward propagating quasi-electrostatic field initiates from the upper charge-layer of thunderstorm. This quasi-electrostatic field connects troposphere with the stratosphere and the lower ionosphere for a very short duration. There are about 40 to 100 lightning discharges occurring every second. Apart from the upward propagating quasi-electrostatic fields, lightning discharge current generates intense electromagnetic pulses of ~20 GW peak powers [34] which may cause significant ionospheric disturbances because of the heating and acceleration of electrons, production of ionization, optical emissions, and so forth.

The upward propagating quasi-electrostatic causes transient luminous events (sprites, blue jets/gigantic jets, elves, etc.) in the stratosphere and the mesosphere which influence the lower ionosphere with additional ionization and formation of ionospheric inhomogeneities and has motivated scientists all over the world to reexamine our understanding of the electrical processes and properties of the atmosphere. Figure 2 shows the variety of transient luminous events and the typical altitude at which they occur. Sprites may occur in cluster of short-lived (~50 ms) two, three, or more carrot-shaped emissions of ~1 km thickness over a horizontal distance of 50–100 km, with the separation between sprite elements of ~10 km [2, 35]. The upper portion of the sprites is red, with wispy, faint blue tendrils extending to 40 km or at time as low as the cloud top and bright region is in the altitude range 65–85 km [35]. They typically last for 5–50 ms and may take the form of one or more vertical columns of a few hundred meter radius for the smaller column sprites or large jellyfish-shaped structures of tens of kilometers of radius and extending from the ionosphere D-region almost down to the thunderstorm cloud tops [2, 35]. The knowledge gained from laboratory experiment of gas discharges at subatmospheric pressure has been used to understand sprite spectroscopy and associated phenomena [25]. Figure 3 shows broad identical spectral characteristics of light of positive column of the laboratory tube and sprites [25]. The difference in spectral characteristics may be due to difference in applied electric field, gas pressure, and gas composition in the mesosphere and gas tube discharges. Physical processes associated with sprites and other optical events are also associated with thunderstorm activity in the troposphere and are thought to result in the gradual build-up of conductivity changes in the lower ionosphere [36]. Liszka [37] suggested the generation of infrasound waves by sprites, whose signatures were detected by a network sensors in Sweden [38]. The shape of the chirp signature in the spectrograms of infrasound can be explained by the horizontal size of the sprite [39]. Neubert et al. [40] have concluded that sprite detection by infrared is an attractive alternative to optical detection, because it is not limited by clear viewing condition or by the absence of daylight.

Elves are concentric rings of optical emissions propagating horizontally outwards at the bottom edge of ionosphere between 75–95 km altitudes caused by the electromagnetic pulse radiated by the cloud to ground lightning discharge current of either polarity. Elves produce average electron density enhancements of 210–460 electrons cm^{-3} over large (165–220 km diameter) circular regions having an assumed 10 km altitude extent [41, 42] and hence produce perturbation in electrical conductivity of the mesosphere which can be evaluated by measuring changes in the amplitude of VLF waves [43, 44] from transmitters and propagating in the Earth-ionosphere waveguide. Mika [45] has discussed experimental data in which the incident VLF transmitter signal seems to be scattered from horizontally extended diffuse regions of electron density enhancements, most likely associated with halos or diffuse regions of the upper part of carrot sprites, rather than small-scale streamers observed at lower altitudes. The electromagnetic pulse (EMP) generating elves also create ionization [46, 47], which depends on its intensity. The individual contributions of different components of constituent gas to the optical emissions of sprite/elves are not known. An attempt should be made to investigate lightning chemistry and energetics in the region of sprites/elves. This may require future studies using a large number of narrow band filters in optical observations and kinetic modeling in theoretical analyses.

The transient luminous events provide a link between tropospheric processes in the thunderstorms and mesospheric processes in the upper atmosphere, and their studies also promise to improve our understanding of the elusive mesosphere, perhaps the least understood layer of Earth's atmosphere. Hiraki et al. [48] suggested that sprites may

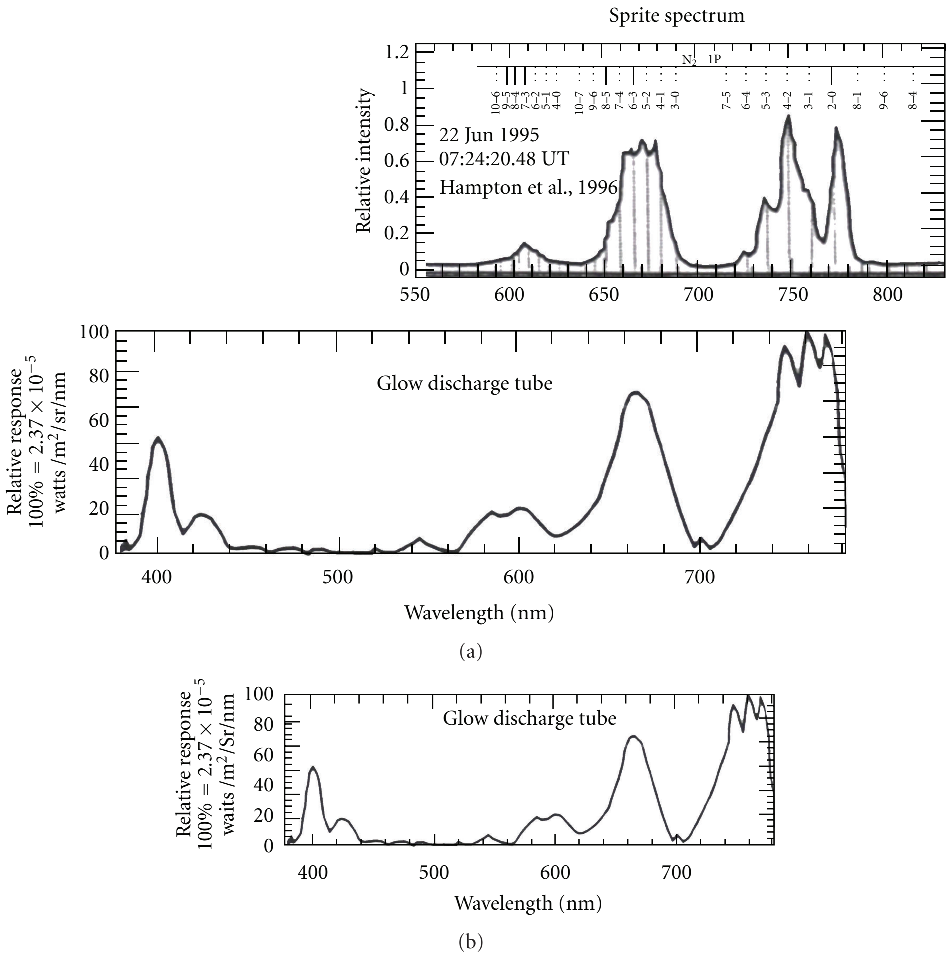

FIGURE 3: Comparison of optical spectra for (a) sprite in the mesosphere and for (b) the positive column of large glow discharge tube, after [25].

change the concentration of NOx and HOx in the mesosphere and lower atmosphere. These chemical changes have impact on the global cooling or heating in the middle atmosphere [49–51]. Nitrogen oxides are critical components of the troposphere which directly affect the abundance of ozone and hydroxyl radicals [52]. Ozone absorbs solar ultraviolet radiation and controls the dynamic balance of the atmosphere. NOx creates ozone in the troposphere and destroys it in the stratosphere and mesosphere and thus affects the climate. This area of investigation remains unexplored.

Lightning generated whistler mode waves propagate along geomagnetic field lines without appreciable attenuation and thus connects troposphere with the ionosphere and the magnetosphere. Whistler mode waves while propagating through the equatorial region of the magnetosphere interact with the Earth's radiation belt trapped electrons and cause their precipitation in the form of plasma inhomogeneities in the high-latitude lower ionosphere. Such a type of coupling has been confirmed in ground-based observations [53], balloon measurements [54], rocket experiments [55, 56], and satellite observations [57, 58].

Thunderstorms and lightning discharges form the major current source in GEC, essential features of which are shown in Figure 4 [26]. Solar wind interactions with the Earth's magnetic generate additional current [59], and potential gradient modulation may arise from coupling of geomagnetically-induced changes in the magnetospheric dynamo through the global circuit. Precipitations from electrified clouds are also current driver [60]. The total current flowing in the atmospheric GEC is ~1-2 kA [27]. A realistic model of equivalent circuit with capacitors, resistors, and switches is shown in Figure 5 [28]. A switch is closed for a short time if a certain type of discharge occurs. For example, switch S_2 (S_3) closes for ~1 ms when positive (negative) cloud to ground discharge occurs for a particular storm. The switch S_1 closes for a few ms when a sprite occurs above a particular thunderstorm and fair-weather time constant, $r\ C \sim 2$ min ($r \sim 200$ ohms, $C \sim 0.7$ F). Generators act over <1% of Earth's surface, and remaining ~99% of the Earth's surface region acts as a load on the circuit. The total current (I) flowing in the circuit is ~1 kA [28]. The GEC is based on the concept that the quantity of electric charge has to be conserved in the Earth's atmosphere-ionosphere-magnetosphere

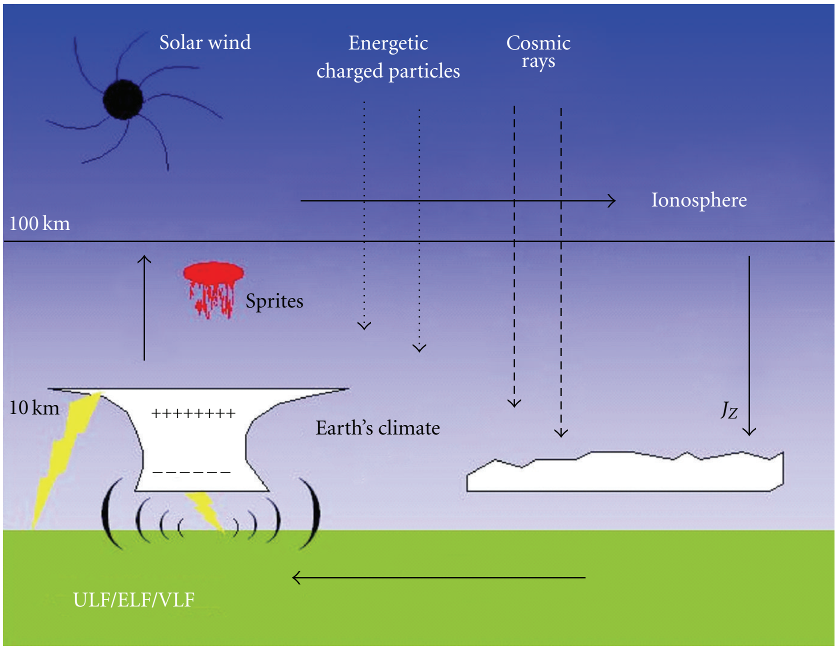

Figure 4: Essential features of the global atmospheric electric circuit [26, 27].

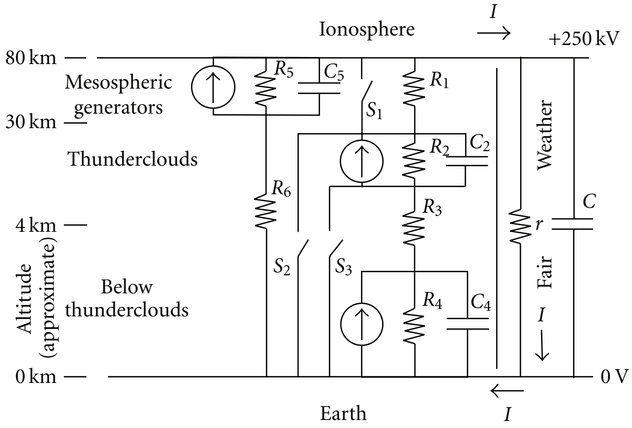

Figure 5: Diagram showing a schematic equivalent circuit for global electric circuits, credit [28].

system, that electric currents redistribute charge and that the electric currents are continuous.

The power supplied by thunderstorms is insufficient to maintain a field of magnitude observed in fair-weather regions. Rycroft et al. [61] included the generator associated with electrified clouds in the GEC model; this was found to be of the same magnitude as that due to thunderstorms. The optical phenomena occurring in the upward branch of the GEC above the thunderstorms are likely to influence only the upper atmosphere conductivity. Since they occur much less frequently (only one sprite out of 200 lightning) because of their association with intense lightning discharges [50, 62], their contribution to the ionospheric potential is very small [61]. The gigantic jets transport large quantities of negative charge discharging the atmospheric capacitor [63–66] whose effects on the ionosphere and GEC have not yet been modeled. The role of sprite/TLE events on the flow, charging/discharging of GEC, modification of electric fields near the Earth's surface remains unanswered. Since optical emissions could change electrical properties of the atmosphere and influence processes related with weather and climate, intense research activity in this area is required.

The earthquakes affect the electrodynamics of the atmosphere through the generation of electric and magnetic fields with crustal deformation, fault-failure-related piezomagnetism, stress/conductivity, electrokinetic effects, charge generation processes, thermal remagnetization, and demagnetization effects, and so forth [67]. These processes in the Earth's lithosphere relate with disturbances in the atmosphere and ionosphere. Sorokin et al. [8] discussed the processes forming the electrodynamic model of the effect of seismic and meteorological phenomena on the ionosphere. Radioactive substances and charged aerosols injected into the atmosphere modify the altitude profile of conductivity, generation of external currents, perturbation of electric field, and current in the ionospheric layer. As a result, Joule heating of the ionosphere and instability of acoustic gravity waves take place, which manifests in the formation of horizontal inhomogeneities of ionospheric conductivity. Finally, excitation of plasma density fluctuations and ULF/ELF emissions in the ionosphere, generation of field aligned currents and plasma layers, upward plasma transport, and modification of F_2-layer, and change in the ion composition of the upper ionosphere take place [68, 69]. These changes may also affect the GEC and the Earth's climate which remains a challenging problem to be solved. Figure 6 shows a schematic diagram which can be used to

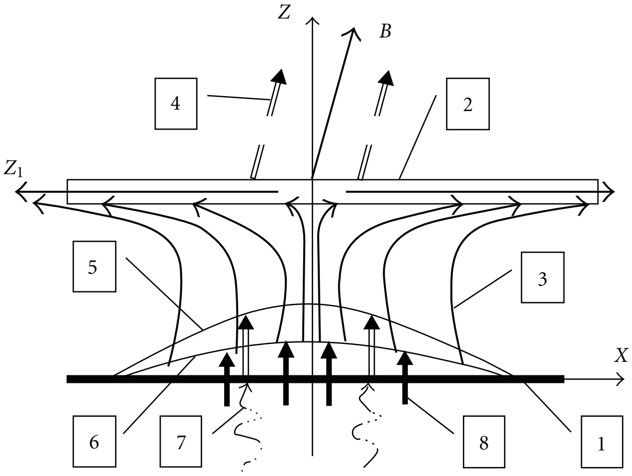

Figure 6: Schematic model used for the calculation of electric field due to the injection of charged aerosols in the atmosphere-ionosphere circuit. 1—Earth's surface, 2—ionosphere, 3—conducting current in the atmosphere and the ionosphere, 4—field-aligned current, 5—zone of upward convection of charged aerosols and external electric current formation, 6—zone of perturbation of atmospheric conductivity induced by radioactive elements emanation, 7—charged aerosols moving upward with soil gases, 8—radioactive elements emanation, credit [3].

compute external currents and enhancement of electrical conductivity in the lower atmosphere that causes an increase in the electric field in the ionosphere due to the injection of charged aerosols and radioactive elements from the solid Earth during earthquakes [3].

There are some other complex processes showing multiple scales of variability. Turbulent mixing and eddy diffusion are few other ways of transport from below. They control the relative abundances of atmospheric species in the mesosphere whose distribution tends to be independent of altitude. As part of a physical mechanism, the influence of internal atmospheric waves may be considered. The upward propagation of internal atmospheric waves (planetary waves, tides, and gravity waves) from the troposphere and stratosphere is an essential source of energy and momentum for the thermosphere and ionosphere. Weaker mesospheric gravity waves will lead to stronger winds in the upper atmosphere, which in turn will affect the ability of planetary waves to propagate, producing an additional feedback route [70]. Of course, the study of internal waves is the province of meteorology, a discipline that has enjoyed a long and independent development of its own and has its own complicated problems, sufficiently different from ionospheric physics that the two are regarded as separate but neighbouring disciplines. However, the internal waves launched by weather fronts or any other sources in the troposphere and stratosphere sometimes appear to be capable of penetrating into the ionosphere, where they dissipate most of their energy. The leakage of wave energy from the troposphere and stratosphere at least up to 100–115 km was introduced as coupling from below [71] and is considered as a mechanism of the meteorological influence on the ionosphere.

3. Various Coupling Processes

Thunderstorms directly couple the atmosphere and the ionosphere. Potential difference between the ionosphere and the Earth is maintained by thunderstorms' pumping action of lightning discharges and electrified clouds. In the Earth-ionosphere cavity, the electric field and the conduction current in the lower atmosphere are primarily controlled by ions. Ions have the characteristic parameters such as mobility, lifetime, and generation rate that vary with altitude. In recent years, some progress has been made towards understanding thunderstorm and lightning [22, 72, 73]. The essential factors in marinating the lightning discharge is the gas breakdown caused by the stored electrostatic charge in the leader head. This extends the channel into new regions. General models of the cloud charge distribution are based on electric field measurements inside a thundercloud and on the ground below the thunderstorm [75]. Earlier, an oversimplified tripolar charge structure consisting of a negative charge in the middle of the cloud, a positive charge above it, and a smaller positive charge below were widely used. Later on, a screening negative charge on the upper cloud boundary was considered [76] which are depicted in Figure 7. In the convective updraft zone of a matured thunderstorm, usually four charge layers are found and outside updraft convection region at least six charge layers are seen. Forward and rearward anvils typically contain positive charges screened with negatively charged layers. However, this model does not represent super cell storms which usually have dominant positive charge at mid-levels in place of the typical main negative charge region [77], that is, super cell storms have "inverted polarity" charge structure, and they produce mainly positive cloud-to-ground lightning. The proposed model (Figure 7) is based on balloon soundings of convective region of storms that occurred in a limited portion of the lower mid-latitudes. Its validity for storms in other mid-latitude regions, the tropics, and high latitudes are yet to be tested because of scarce *in situ* data.

The global electric circuit (GEC) links the electric field and current flowing in the lower atmosphere, ionosphere, and magnetosphere forming a giant spherical condenser [50, 59, 78], which is charged by thunderstorms and other generators to a potential of several hundred thousand volts [79] and drives a vertical current through the fair weather atmosphere's columnar resistance ($\sim 1.3 \times 10^{17}\,\mathrm{ohm\,m^{-2}}$). Recently, Stolzenburg et al. [30] examined electric field data of 32 balloon soundings through MCS (mesoscale convective system) stratiform regions and inferred that for 15 cases the stratiform cloud was charging the GEC, while in the other 17 cases the cloud was discharging the circuit. Thus, the overall effect of MCS on GEC could be very large or very small. Davydenko et al. [80] modeled the quasi-electrostatic electric fields and currents inside and near an isolated MCS producing positive discharges and also sprites and showed that the large (~25 A) cloud-to-ground, quasi-DC current discharges the GEC. Their full impact on the GEC and that of the positive cloud-to-ground flashes which they initiate remains to be quantified. The vertical current causes weak electrification of stratified clouds [81] and produces a vertical

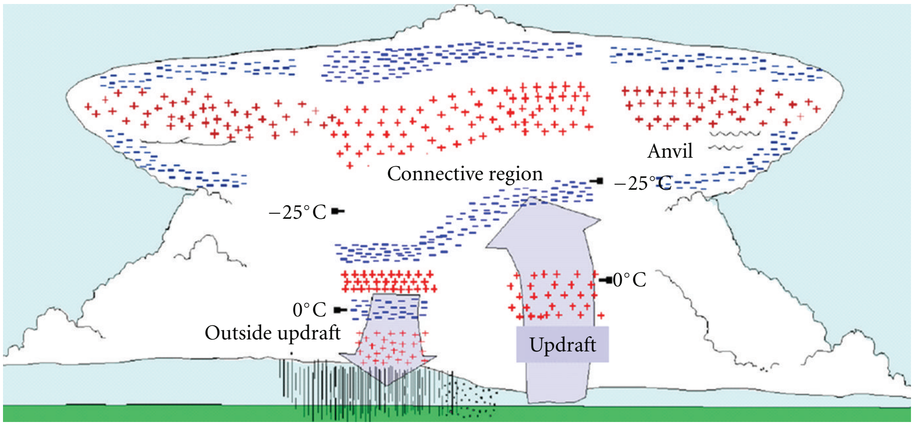

Figure 7: Conceptual model of the charge structure within an idealized isolated, mature thunderstorm based on 49 balloon sounding through different clouds, credit [22, 76].

potential gradient in the atmosphere near the Earth's surface. The circuit is closed by a horizontal current flowing through the highly conducting Earth and the ionosphere, and by vertical currents from the ground into the thunderstorm and from the top of the thunderstorm to the ionosphere.

3.1. AC Phenomena. Thunderstorm is the main source of both AC and DC coupling of the lower atmosphere and the ionosphere through lightning discharges. Return stroke of lightning discharge produces a pulse of radio energy containing waves from a few Hz up to several MHz. These signals propagate in the Earth-ionosphere wave guide over long distances (several thousand kms).The lowest frequencies of the discharge spectrum are ELF (3–3000 Hz) waves which excite the Earth-ionosphere cavity at 8, 14, 20, 26,...Hz, commonly known as Schumann resonances [82]. Resonances are being continuously excited because lightening is always occurring all over the world. Recent interest in Schumann resonance studies arose because the charge movement change (CMC) of the parent lightening discharge can be evaluated by measuring the contribution of each mode in the resonance pattern which has been used in TLEs studies [83–85]. Thus, coupling between the atmosphere near the surface of the Earth and the ionosphere can be studied on the time scale ranging from a fraction of second to less than 1 μs.

Some of the wave energy from lightning generated wave spectra propagates into the ionosphere and magnetosphere system, where it interacts with ambient plasma particles and affects the global ionospheric/magnetospheric energy budget. Waves in the very-low-frequency (VLF, 3–30 kHz) range propagate in the ducted mode along the geomagnetic field lines [86] and cause magnetospheric electron precipitation into the lower ionosphere, leading to D-region conductivity modification [87, 88]. Unducted VLF wave propagation can also take place [89]. Precipitating charged particles may participate in dissociation and ionization processes. There are VLF signatures of ionospheric disturbances associated with sprites [29, 43, 90, 91].

Hydromagnetic waves in the ultra-low-frequency (ULF, <3 Hz) propagate through the magnetosphere in one of several different modes at speeds considerably less than the speed of light. These waves interact with the ions in the ionosphere and magnetosphere. ULF waves sometimes are called magnetospheric analogues of seismic waves, which enable remote sensing of volumes from point measurements [92]. Waves in the frequency range $\sim$0.1–5 Hz also excite the ionospheric Alfven resonator (IAR) [93, 94] which is centered on the maximum of the ionospheric F_2-region where the refractive index for Alfven waves has a maximum value. The variation of spectral resonance structure of the IAR over a solar cycle has also been studied [95]. The boundaries of IAR are at $\sim$1000 km altitude in the topside ionosphere and in the E-region ionosphere.

The ULF-VLF electric fields were detected up to topside ionosphere over powerful Pacific Ocean typhoons [96]. However, details of the mechanisms are not yet known. Ionospheric heating due to lightning electromagnetic pulses was considered and modeled [97, 98]. Large amplitude radio waves from ground-based transmitters at VLF [99] and high frequency (HF, 3–30 MHz) [100] have been used to study ionospheric heating and modification. The associated phenomena include perturbations of electron density and temperature (increase of ionization at E-region, E-sporadic occurrence, increase of temperature, and electron density in F-region), excitation of electrostatic wave turbulence, and enhanced optical emissions.

The heating of the lower thermosphere by lightening-generated electromagnetic pulses may result into electrical breakdown and production of sprites and other optical emissions [101, 102]. The more exotic relativistic runaway (avalanche) breakdown mechanism, which can produce bremsstrahlung and gamma-rays radiations, has also been proposed and discussed [31, 103, 104]. Rowland [47] had reviewed both mechanisms. The two processes are coupled in the sprite streamer: the thermal discharge produces a beam of relativistic seed electrons that allow ignition of runaway relativistic discharge [105]. The thundercloud electric field at the lower thermosphere altitude is very transient, $\sim$1–10 ms, consequently the observed sprite and halo phenomena are also of transient nature. The conventional breakdown mechanism explains most observations of sprites and their associated phenomena. Gerken and Inan [106] indicated that relatively faint and diffuse sprites confined to lower altitude could be associated with very high-peak currents and short-duration lightning discharges. Adachi et al. [107] reported that the number of columns in a sprite event was proportional to the peak current intensity of positive cloud-to-ground discharges, which was not corroborated by the results of van der Velde et al. [108]. This suggests a complex relationship between sprite morphology and in-cloud lightning processes, which are not yet fully understood.

Streamers associated with sprites are needle-shaped filaments of ionization and are driven by enhanced electric fields due to charge separation in their head, and the sign of the charge in head determines polarity of streamers. Liu and Pasko [109] have modeled preionization ahead of the streamer by ionizing ultraviolet photon originating in the streamer head. Thus, they consider photo ionization to be important in determining the propagation and branching of sprite streamer. The presence of inhomogeneities in the background density could also be helpful in the formation of streamers [110]. They have also explained the polarity asymmetry in triggering sprite streamer. Blue jets sometimes appear at the top of an energetic thundercloud and propagating upwards with a vertical velocity of ~100 km s^{-1} to a maximum altitude of ~40 km or so. These are believed to be a positive streamer formed in the upward quasi-electrostatic field above the cloud [63, 101]. Many streamers originate from the surface of the leader head (both positive and negative).

Pasko and George [111] have modeled the branching streamers as fractal tree growing in three dimensions. Pasko et al. [112] reported an unusual blue jet above a relatively small thunderstorm cell in Puerto Rico, and propagating up to ~70 km altitude. Its characteristics above 42 km resembled those of sprites but having longer duration. This shows that an electrical contact was made between the top of the thunderstorm and the lower ionosphere. Gigantic jets extend from the cloud top to the ionosphere at 90 km altitude and can last up to ~0.8 sec [64, 113–115]. The observed gigantic jets were of negative polarity, produced by a normally electrified storm and therefore resembled to negative cloud-to-ionosphere discharges. Out of five gigantic jets, four events were found to be associated with ELF radio waves, while no cloud-to-ground lightning was observed to trigger these waves. This indicates that ELF waves were generated by negative cloud-to-ionosphere discharges. Each event reduces the ionospheric potential by removing 30 coulombs from the ionosphere [64], and their effect needs to be included in the GEC model.

3.2. DC Phenomena. In the atmospheric GEC, thunderstorms are thought to act as a giant battery distributed over the globe causing electric potentials up to ±100 MeV [74, 116], which are discharged in short (~1 ms) time scales by cloud-to-ground or intracloud lightning. Even upward discharges like gigantic jets also discharge the GEC. Such large potentials could produce energetic photons, X-rays [117], and even gamma rays [118], which are absorbed in the short distance in the lower atmosphere but could travel appreciable distance before being absorbed in the middle and upper atmosphere.

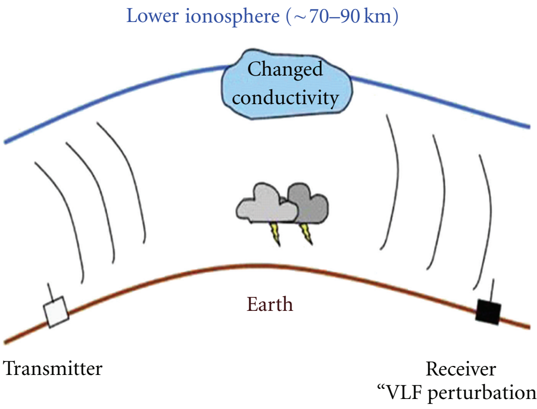

Figure 8: Diagram showing how the bottom side ionosphere and the mesosphere above a thunderstorm are probed by ground based transmitter, credit [40].

The inherent current sources [119, 120] in the mesosphere may generate large DC electric fields in the 50–70 km region [121], which has been observed via rocket measurements [122, 123] and remotely via a series of MF radar measurements [124–127]. The large DC electric fields increase the electron temperature and effective collision frequency in D-region. The enhanced electron temperature over neutral temperature violates the local thermodynamic equilibrium. During the tropospheric disturbances, tropospheric conductivity increases and the electrical coupling between the troposphere and the mesosphere results in grounding the mesospheric current source and in a significant decrease in the intensity of large mesospheric electric fields. The electron temperature and effective collision frequency decrease, which results into the D-region cooling [128, 129].

The upward electric currents associated with the charge separation process for a single active thunderstorm are ~1 A. Assuming ~1000 thunderstorms operate at a time over the entire globe, there is an upward current of ~1000 A. Theses currents charge the highly conducting ionosphere (~80 km altitude) to a potential of ~250 kV with respect to the Earth. The total charge on the plates of the Earth-ionosphere capacitor is ~2 × 10^5 C [59]. The electric currents (~2 pAm^{-2}) flowing from the ionosphere to the Earth's surface remote from thunderstorms depend on the electrical conductivity of the medium. The conductivity may change due to the incident flux of cosmic rays, precipitation of energetic charged particles from the magnetosphere, changes in aerosol distribution, changes in the pressure, and the temperature distribution in the troposphere. The upward quasi-electrostatic fields also change the atmospheric/lower ionospheric conductivity. Figure 8 shows the measuring principles of the change in the electrical conductivity above thunderstorms in the mesosphere and the lower ionosphere by measuring changes in the amplitudes of signals radiating from narrow band radio transmitters passing over thunderstorms region [40]. Global warming affects distribution of aerosol, temperature, and concentration of gases in the troposphere and stratosphere and hence modifies the dynamics of the lower and the middle atmosphere [130]. These changes result into changes in thunderstorm and lightening properties. It would be interesting to study the changes produced in the GEC by the global warming phenomena.

In the study of electrical coupling of the atmosphere and the ionosphere, the latter is considered to be equipotential surface, which is not exactly true. During very active auroral conditions, the potential difference across the narrow (1° or 2° wide) auroral electrojet region may become ∼100 kV. Even ionospheric dynamos may create potential differences of ∼15–20 kV between low and midlatitudes. These potential differences contradict the concept of the ionosphere as an equipotential surface. Ogawa et al. [131] have studied the variation of horizontal electric field in the middle atmosphere. The issue of equipotential further complicates because spatial and temporal variations of these potentials have a variety of scale lengths and various time scales. Intense atmospheric disturbances caused by earthquakes, volcanoes, tropical storms, typhoons, and so forth also affect electrical properties of the lower ionosphere. Some definite progresses in experimental and theoretical studies of man-made and natural effects on the ionosphere have been recently made [3]. However, there is significant gap in the understanding of an origin and interconnection of many processes involved in the atmosphere-ionosphere coupling.

4. Summary

The electrodynamic coupling between the Earth's atmosphere and the ionosphere is very complex and described by the global electric circuit. Currently, many aspects are not well understood. Recent measurements show that coupling influences both the electron density and electrical conductivity. Thunderstorms are the main generators situated in the troposphere. Measurements and theoretical studies have led to some understanding of charging mechanisms and charge structures of thunderstorms, however various aspects remain unanswered. Thunderstorms are large, complex, and short-lived phenomena; the charge generation and separation mechanism and charge structure are not known, and it is difficult to model them. The electrical processes are intimately related to the cloud dynamics or motions and to the microphysics of the clouds which are incompletely known or understood. Their detailed comprehension is essential as it controls climate and its variability. For proper understanding, it is essential to make simultaneous measurements of electric parameters from different parts of thunderstorms at small time intervals.

The role of transient luminous events on the local ionospheric potentials, modification of the electric field near the Earth's surface, and charging/discharging of GEC are yet to be quantified. Even there is dispute about the breakdown mechanism involved in the mesospheric discharges generating sprites, blue jets, elves, and so forth. Lightning-generated whistler mode waves cause precipitation of Van Allen belt electrons which modify D-region conductivity. The relative importance of different types of whistler mode waves is not known.

The generation of transient mesospheric electric field needs detailed study as it provides a basis for developing coupled troposphere-mesosphere-ionosphere electrodynamic models under disturbed conditions. In fact, numerous phenomena that occur in the upper atmosphere of the Earth are caused by the sources located in the lower atmosphere and on the ground such as thunderstorms, typhoons, dust storms, earthquakes, volcanic eruptions, and radioactive emissions from the nuclear power plants. All these phenomena affect the electrical conductivity from the Earth's surface to the lower ionosphere. Variation of conductivity and external current in the lower atmosphere lead to the perturbation of electric current flowing in the GEC and to the associated DC electric field perturbations both on the Earth's surface and in the ionosphere and hence affect the electrodynamic coupling of the Earth's atmosphere and the ionosphere.

UNITED STATES PATENT OFFICE.

MARK W. DEWEY, OF SYRACUSE, NEW YORK, ASSIGNOR TO THE DEWEY CORPORATION, OF SAME PLACE.

METHOD OF UTILIZING NATURAL ELECTRIC ENERGY.

SPECIFICATION forming part of Letters Patent No. 414,943, dated November 12, 1889.

Application filed May 1, 1889. Serial No. 309,171. (No model.)

To all whom it may concern:

Be it known that I, MARK W. DEWEY, of Syracuse, in the county of Onondaga, in the State of New York, have invented new and useful Improvements in the Method of Utilizing Natural Electric Energy, of which the following, taken in connection with the accompanying drawings, is a full, clear, and exact description.

The object of this invention is to provide a method whereby natural electrical energy—such as the so-called "atmospheric electrical energy," or electrical energy that may be derived from the difference of potential existing between two points, one being the earth and the other the atmosphere at an elevation above the earth—may be collected or utilized for the various uses to which electricity is applied.

It has been found that the presence of electricity in the upper regions of the atmosphere is not confined to thunder-clouds, but can be detected at all times and often in great quantities in different conditions of the atmosphere. In fine weather this electricity is mostly positive; but in showery or stormy weather negative electricity is as frequently met with as positive, and it is in such weather that the indications of electricity, whether positive or negative, are usually the strongest. It has also been found that as we proceed farther from the earth's surface, whether upward from a level plane thereof or horizontally from an elevation, the potential of points in the air becomes more and more different from that of the earth, the difference being, in a broad sense, simply proportional to the distance; hence we can infer that there is electricity residing on the surface of the earth, the density of which at any moment in the locality of observation is measured by the difference of potential found to exist between the earth and a given point in the air near it. The results of observations show that the variations of the electricity residing in the atmosphere is the main cause of the variations of the electricity on the surface of the earth. A charged cloud or body of air induces electricity of the opposite kind to its own on the parts of the earth's surface over which it passes and produces such variations. The difference of potential in increasing the distance from the earth is due to electricity induced on the surface of the earth by opposite electricity in the air overhead, and the air being a nonconductor the electricities are unable to combine. As electrical density is greater on projecting parts of a surface than on those which are plane or concave, stronger indications are obtained on hills than in valleys, if the collecting apparatus be at the same distance from the ground in both cases. The average difference of potential is greater in the winter than in the summer. Little or no effects can be obtained within inclosures or under trees, as they tend to screen the apparatus.

Inasmuch as electricity travels in preference through the best conductors, it follows that if a path of low resistance is formed (such as the erection of a metal pole) to a sufficient elevation above the earth the electricities in the atmosphere and that on the surface of the earth will tend to combine and travel through the said path in a current or currents, and if this pole terminates in a metal point or a number of such points the earth and clouds exchange their opposite electricities without a disruptive discharge—as the lightning—but in a slow and gradual way through convection. Besides supplying the top of the pole with points, a metal plate to which the said points are fixed attracts the opposite electricity in the atmosphere. In order to obtain a greater and increased effect, a large metal plate is buried at the foot of the pole and electrically connected therewith, and is provided with points or branches extending in different directions in the ground. The plate and branches may be surrounded by metallic refuse, coke, or other good conducting substance. The metallic points on the top of the pole should be sharp, and preferably of copper, and may be platinized, gilded, or galvanized to prevent corrosion. It having been ascertained by practical experiments that either a flame or dropping water at an elevation above the surface of the earth produces convection of electricity, it is obvious that such means may be employed in place of the points hereinbefore referred to. As the electricity in the atmosphere is sometimes positive and other times negative, the direction of the currents is not always the same—that is, the atmospheric electrical energy is composed of a current of an alternating character, flowing in one direction on an average about as much of the time as in the opposite direction, but the length of the current in a certain direction, or the lengths of time between reversals or changes in the direction of its flow, is greatly varied. This and also the varied strength of the currents have prevented the utilization of atmospheric electrical energy in commercial quantities for the various purposes for which electricity is generally employed. In order to utilize such a current or currents, they should be transformed into a continuous direct current of uniform strength. The apparatus for accomplishing the transformation of atmospheric electricity into a direct current of uniform strength is susceptible of being greatly modified. The preferred form of apparatus, however, for carrying the invention practically into effect I will now proceed to describe to show that the method is capable of actual performance. Said apparatus is illustrated in the diagram accompanying this specification.

Referring specifically to said diagram, A represents a metallic pole, which is shown bare, but may be enveloped in suitable insulating material, if desirable. B is the base of the aforesaid pole, which base is of insulating material set in the ground E. C is a large metal plate beneath the said base, and has points or branches *c'* extending therefrom in different directions in the ground. C' is a metallic post extending from the said plate above the surface of the ground and having a terminal *d* of the circuit D. On the top of said pole is mounted a metallic cap F, consisting, preferably, of a convex disk provided with sharp iron or copper points *p*, which project in all directions from the same. As before mentioned, the said points may be plated with a suitable metal that forms a good conductor and prevents corrosion. Similar caps F' may be placed on other insulated poles, as A', in the vicinity, and connected with the main pole A by an electric conductor *a*, for increasing the effect. The pole A' may be of wood, and the pole A may also be of the same material if provided with a metal conductor within or on the outside, extending from the cap to the other terminal *d'* of the circuit D. The said circuit D leads from the terminal *d* through an automatic variable resistance G, thence to one of the poles of a secondary or storage battery H, and from the other pole of said battery through an automatic current-regulator to the terminal *d'*. An automatic current-reverser or pole-changer J is located in the said circuit for reversing the current whenever there is a change in its direction, so that it may be rectified or straightened during transit and caused to travel at all times whether its direction is toward or from the earth in one and the same direction through a portion of the circuit containing the secondary battery. The reversals are accomplished automatically by means of a pivoted polarized armature *b*, located between two electro-magnets *c c*, having their coils included in a shunt-circuit between the leads of the circuit D. The magnets are wound so that a north pole will be presented to the armature on one side and a south pole on the other. When the current is flowing in a certain direction, the said polarized armature will be repelled by one magnet and attracted by the other, and thereby moved to one side. When the current changes its direction through the magnets, the poles of the said magnets are reversed and the armature is both repelled and attracted to the other side. An arm *b'*, of diamagnetic material, is fixed to and extends from the armature and is moved by the same. Between a movable end of the arm and the said current-reverser is a pivoted connection or link *e*, by which the motion of the arm is conveyed to the reverser. Stops *f* are provided for limiting the movement of the said arm, and an adjustable resistance *d'* is included in the shunt *d''* to regulate the current through the same.

The current-regulator hereinbefore referred to prevents short-circuiting or the rapid discharge of the secondary battery into the air and ground when the strength of said battery-current becomes greater than that passing to the battery. Said regulator is composed of an electro-magnet I, having its coil in the circuit D. A pivoted polarized armature *g* is connected at its pivot to one terminal of the coil of said magnet, and when the current is flowing to the battery said armature is attracted by the magnet I and held in contact with the stop *h*, to which the terminal of the secondary battery is connected. In the aforesaid condition a free or low-resistance path for the current is provided to the battery; but when the battery-current exceeds the charging-current the magnet-poles are reversed and the armature is repelled by the magnet, and the free path of the circuit is broken between the armature *g* and stop *h*. In order to maintain the armature in the latter position until the charging-current has been increased in strength above that of the battery-current or discharging-current, and so that the said regulator will automatically operate, a shunt path K of high resistance is provided around the armature *g* and stop *h*. The high resistance of the said shunt is obtained by including a rheostat *m*. This shunt path or circuit K, with the resistance, permits a small but sufficient amount of current to flow through the magnet I to hold the armature away from the stop *h* until the current is reversed, and then move the armature back to stop *h* to close the free or low-resistance path. A spring *i* is provided to assist the movement of the armature from the magnet when it is repelled by the same.

The electric current may be directly conducted to translating devices—such as lamps or electromotors; but, as hereinbefore stated, said current is preferably employed to charge one or more cells of the secondary battery H, and this battery stores or accumulates the electrical energy and supplies the said translating devices. To illustrate the latter feature, leads or wires L and L′ are extended from the poles or electrodes of said battery, and translating devices, in the shape of incandescent lamps *l*, are connected with the said wires in multiple arc. In the wire L is a common circuit maker and breaker *n* to close and open the circuit to the lamps. The said battery may be charged in series or parallel.

The automatic variable resistance G maintains the current flowing through the circuit D approximately uniform by increasing the resistance therein upon an increase of strength. Said resistance is not absolutely necessary and may be dispensed with.

The lightning-arrester M is to short-circuit a very heavy current to prevent the same from passing through the other parts of the apparatus and injuring it. A low-resistance shunt O, with a circuit maker and breaker therein, is connected between the leads of the circuit D, near the terminals *d* and *d′*, to completely short-circuit the apparatus when desired.

Having described my invention, what I claim as new, and desire to secure by Letters Patent, is—

1. The method of utilizing atmospheric electrical energy, consisting in conducting the electric current or currents between the earth and a point in the atmosphere at an elevation above the earth, rectifying or straightening the currents during transit, and storing or accumulating the electrical energy of said rectified current or currents.

2. As preliminary steps in the method of utilizing atmospheric electrical energy, conducting the electric current or currents through a path of low resistance between the earth and the atmosphere at an elevation above the earth, maintaining an approximately uniform strength of current and rectifying or straightening the same during transit.

3. As preliminary steps in the method of utilizing atmospheric electrical energy, conducting the electric current or currents through a path of low resistance between the earth and the atmosphere at an elevation above the earth, and rectifying or straightening said currents during transit.

4. The method of utilizing atmospheric electrical energy or deriving energy from the difference of electrical potential existing between the earth and a point or points in the atmosphere at an elevation above the earth, consisting in conducting the current or currents between the two points through a path of low resistance, rectifying or straightening the said currents in a portion of the path during transit, and storing or accumulating the electrical energy thereof.

5. The method of utilizing atmospheric electrical energy or deriving energy from the difference of electrical potential existing between the earth and a point or points in the atmosphere at an elevation above the earth, consisting in conducting the current or currents between the two points through a path of low resistance, maintaining an approximately uniform strength of current, rectifying or straightening the said currents in a portion of the path during transit, and storing or accumulating the electrical energy.

6. The method of utilizing atmospheric electrical energy composed of a current of a varied alternating character, consisting in conducting the electric current or currents through a path of low resistance between the earth and the atmosphere at an elevation above the earth, and then accumulating the electrical energy of said current or currents while flowing in both directions in one or more cells of a secondary or storage battery, as described.

In testimony whereof I have hereunto signed my name this 29th day of April, 1889.

Friends, the "fever" around topics about alternative energy has made scammers excited too! Be vigilant and don't fall for cheap scams. Remember that if you are offered to buy a working BTG at a price less than a million dollars, then by 99% this is a scam for money. If you are offered to buy BTG for more than a million dollars, then this is a 100% scam. Alas, there are no miracles and exceptions yet, although you can always check it yourself... :-)

Иллюстрация листовки описания "Устройства для получения энергии из электрического поля атмосферы" Патент RU 2245606

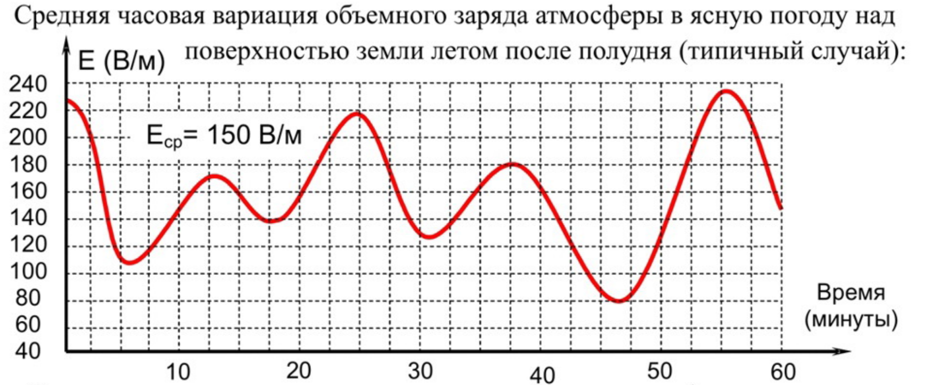
maybe it will be useful for someone for experiments...

---

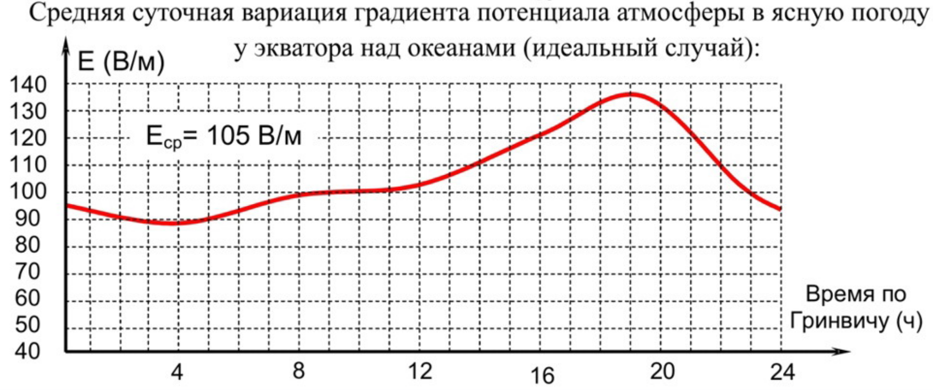
here is a small excerpt from the "theoretical" description:

===

Does the Earth have its own electric field? Who remembers its characteristics?



Средняя часовая вариация объемного заряда атмосферы в ясную погоду над поверхностью земли летом после полудня (типичный случай):



Средняя суточная вариация градиента потенциала атмосферы в ясную погоду у экватора над океанами (идеальный случай):

For absolutely clear weather, near the equator, the vertical electric field strength at the sea surface is ~ 130 volts per meter. That is, by raising your hands above your head, you will get between your fingers and boots, a voltage difference equal to the amplitude voltage in a conventional outlet, about 310 volts. Why doesn't anyone notice this? Firstly, the body is a conducting object and its potential almost coincides with the ground potential. Secondly, air is an excellent insulator and electric current flows through it at much higher intensities. About 30 kilovolts / cm, yeah ... And even in this case, the current through the air is indecently small, milliamps and fractions of a milliamp. Anyone who has been in the mountains and seen how the “fires of St. Elmo” appear on the fingers and points, in bad weather, is familiar with the extreme version of atmospheric electricity. And personally, such lights were shown to me at school, with the help of an electric car. You are standing on a dielectric stool, in a darkened classroom, someone is turning the handle of the unit, and you have your hair sticking up in all directions and blue corona discharges are burning on your outstretched arms. M-dya ... And if, on the same "electric stool" to put a girl with long hair - a spectacle outrageous. The field spreads her hair in a "sheaf" in all directions, each hair separately ... Screeching, screaming, sparks ... to put a girl with long hair is a sight to behold. The field spreads her hair in a "sheaf" in all directions, each hair separately ... Screeching, screaming, sparks ... to put a girl with long hair is a sight to behold. The field spreads her hair in a "sheaf" in all directions, each hair separately ... Screeching, screaming, sparks ...

The same effect can be obtained with very simple, almost home remedies. It is enough to have a high lightning rod at hand or launch a balloon or a kite into the sky, on a metal wire. The simplest arithmetic. If with each meter the voltage increases by 100-200 volts, then already a few tens of meters above the ground conditions arise for the breakdown of air by an electric discharge.

It can be calculated specifically. Do you know the lightning rod formula? Come on! Okay

... I understand that you would never need it in your life, therefore you didn't fill your head with nonsense ... Who knew that fortune would turn its back? Well, I remind you - "The lightning rod protects the site from atmospheric discharge (lightning), in the form of a circle circumscribed around its base, with a radius equal to its height." Why? Because the lightning rod is a voltage concentrator, and all the force lines of the atmospheric electric field, which were previously evenly distributed over this site, are now "pulled" to its top. There, on occasion, lightning will strike from a thundercloud. Towards the "leader" developing from the top of the lightning rod. I mean, first, a corona discharge will appear above its elevated part, and from there it will pull a chain of air ions, sufficient to break through lightning of the "linear" type. God, guys, why do you have such gloomy faces?

The question is, is it possible to obtain a similar effect (a gas discharge on a highly raised electrode) in clear, cloudless weather? And if so, what does it give us in a practical sense? After all, outside the discharge, the air will remain a dielectric. Then why? There is a reason and meaning, however... Where does the electric charge of the atmosphere come from? What feeds and sustains it, um... billions of years?

По опыту эксплуатации солнечных электростанций разных типов, совершенно безопасная норма использования - 1,5% от среднего потока энергии.

Approximately 40% of the energy of the sunlight falling on the Earth, in the course of the return radiation into space, for some time (the section of convective heat exchange) is converted into the energy of a potential electric field. The charge of the tropopause and the stratosphere is produced by flows of heated air with an admixture of water vapor ascending from the surface of the planet. The natural leakage of this charge is carried out due to the ionization of air by cosmic rays, thunderstorms, rain and snow falling on mountain peaks. Have you ever wondered why high peaks are always covered with snow caps? There, the same electric field, day and night, pulls the charged ice dust hanging in the upper layers of the atmosphere.

However, let's start from afar, from space. The temperature of any celestial body is rigidly set by the integral power of external radiation absorbed by its surface and internal heat release from the depths. For the Earth, the average annual flux of sunlight ranges from 250-300 W/sq. meter at the equator up to 50-120 W/sq. meter in the polar regions. Cooling in a vacuum, of course, is purely radiative.

The sum of the energy fluxes reaching the surface is exactly equal to the energy flux radiated back into space. But, many planets of the solar system (in particular the Earth) have an atmosphere. They have only the stratosphere (from where thermal radiation goes into the world space) is close to the norm of the thermal balance (for the Earth, about -25 degrees C). On the surface of a celestial body surrounded by a gaseous shell, it is always much warmer. This thing is called the "greenhouse effect".

Any atmosphere is a spectral filter with multiple transparency windows. It can transmit light of a strictly defined range. Since the maximum of the return (thermal) radiation from the surface is always shifted, relative to the absorbed, to the long-wave region, then radiative cooling (like naked asteroids) is also impossible. Radiation from the surface does not diverge, heating the surrounding air. To remove thermal energy into space, a very productive mechanism with a material coolant is needed. In the dense part of the gas envelope of the planets (up to and including the stratosphere), heat transfer is almost entirely convective. The Earth's troposphere (this is below 12-17 km) contains 90% of the mass of air and 99% of atmospheric moisture. The heat flow "surface-space" there is due to the mechanical movement of air masses. This is an extremely rough model of the process. Now, its important detail.

The balance of radiative energy inflow and convective heat outflow requires a rapid vertical movement of the coolant. There is a sharp drop in temperature and pressure along the height. The thermal pressure between the surface of the planet and the upper boundary of the troposphere (altitude 12-17 km) is quite large (on Earth in the equator region from +45 degrees C at sea level to -70 degrees C in the tropopause). But, by itself, convective heat transfer still cannot cope with the load. Energy stupidly "gets stuck" in the lower layers of the atmosphere. Air is an extremely poor heat transfer medium. As a result, the main burden of energy transfer through dense layers of surface air usually lies with the much more productive effect of phase transitions, which acts in parallel with convection. The atmosphere is clearly stratified in height into layers that differ in composition, density and temperature. Moving from heat to cold and back, some of the components of air flows cyclically change their state of aggregation (evaporate, absorbing heat, and condense, giving it away). At the moment of condensation, in the upper layers of the atmosphere, each molecule emits a quantum of radiation leaving for the world space. On Earth, the "working body" of the described heat pump during phase transitions is water, on Venus - sulfuric acid, on Jupiter - ammonia.

In different regions of the planet, due to the evaporation of water from the surface and its re-evaporation in the clouds (water aerosol strongly absorbs infrared radiation), up to 10-55% of the integral solar energy flux is transferred from the troposphere to the stratosphere. The average content of water vapor in the Earth's atmosphere does not exceed 0.3-0.4%, but the energy consumption of its evaporation-condensation is huge and the total contribution of evaporation and condensation in the work of the "atmospheric heat pump" prevails. This ensures more than 95% of the heat exchange between the surface and the stratosphere. The process goes on around the clock. It is most intense in the tropical zone over the oceans, but is noticeable even over the eternal ice during the polar night. In middle latitudes, during the winter, up to 25-30% of the snowfall evaporates.

The work of the described atmospheric mechanism is accompanied by peculiar side effects. A change in the state of aggregation of a substance dramatically changes its dielectric constant. Spontaneous electrification always occurs at the phase boundary. Part of the thermal energy of the air components is converted into electricity... Condensation of water vapor in the cold upper layers of the gas envelope is accompanied by the accumulation of a large number of positively charged particles there. This is how space charges arise, which form a continuous layer in the upper layers of the Earth's atmosphere.

The uppermost layers of the atmosphere are highly ionized by cosmic radiation and represent a region of high conductivity. Result? Noticeable changes in the field strength over any point on the planet's surface are accompanied by a rapid redistribution of charges in the stratosphere and ionosphere. Therefore, the average intensity of the atmospheric field throughout the planet is almost stable.

The electric field of the lowest layers of the atmosphere, however, is very variable. It is associated with the smallest droplets of water and ice crystals suspended in the air. Free charge carriers (ions and electrons) are almost absent in the troposphere. This gives insulating properties to dense layers of air and prevents self-discharge of the aerosol mass. Due to the low mobility of condensate particles, volumetric electric charges (clouds, jets of fog, etc.) are strongly associated with carrier turbulent flows and move with them for a long time (often for weeks) until they evaporate, discharge onto mountain peaks or fall to the surface with precipitation. So "jet" electric currents in the stratosphere and mirror-like "telluric" currents in the upper layers of the earth's crust. Result?

A positive space charge of about 0.57 million coulombs constantly hangs in the atmosphere. It creates an electric field with the already mentioned average intensity of 130 V/m. The field pulsates in time with the rotation of the planet (its intensity is maximum at 17:00 GMT, when the Pacific Ocean floats on the sunny side). The average potential difference between the surface and the stratosphere is about 400 kV. This is in any good physics textbook.

The total energy resource of the charged atmosphere (~ 40% of the integral power of solar radiation in the earth's orbit) is estimated at about 2.5-5 per ten to the seventh power of gigawatts. It covers the Earth from pole to pole and is like a global DC distribution network connected to an eternal, free and environmentally friendly source of energy - the Sun.

We return to where we started. There is a stick. On a stick - an insulated wire to the very top. At the end of the wire is an air ionizer. Yes, it doesn’t matter what ... It doesn’t matter at all ... A corona discharge, a heated wire, an open flame, a piece of a radioactive isotope ... The main thing is that around this elevated conductor, let’s call it a “receiver”, an excess of ions. Free charge carriers. Yeah, I see it's starting to get...

Air is a moving substance. If the charge left the conductor and escaped into the atmosphere, then its fate is indifferent to us. The electric field, of course, will drag him to the right address. And since there is a flow of charges, then an electric current flows in the circuit. Well, yes, through the air ... The strength of this current depends only on the performance of the ionizer. How many charge carriers he throws out of the metal every second, so many pendants of electricity will flow through this conductor. What is air resistance? And it doesn't exist, practically. can be considered equal to zero. It doesn't matter how we connected directly to the stratosphere, all 400 kilovolts of celestial voltage hanging over our heads seem to be sitting at the end of a lightning rod...

Unclear? Oh, guys and girls, what are you all ... Okay, I'll explain about air resistance. On the contrary... Do you know what grounding is? Well, yes, an iron pin driven into the ground to drain current from the protected equipment. If anything gets there, everything will “close” to the ground and disappear safely in the ground. Now a question for backfilling. What is the earth resistance value? Well, yes, if we take a couple of identical grounds, measure the resistance between them and divide them in two, we will just get the desired value. So, how much? But no! A good ground should have resistance in the order of an ohm. Yes, sir. In any soil, even in dry sand or rock. And don't care about the resistance of the material. In-in ... The main thing is to ensure good contact with the volume, albeit of poorly conductive material. The earth is big. Consequently, the earth's resistance tends to zero, and all resistance losses - only at the point of contact with the earth. Where the charge carriers move densely enough. And all problems are solved. The cross-sectional area of the worst "conductor", when the current spreads in the volume, with the distance from the ground electrode, increases as the square of the distance. Exponentially... Very fast. And just as quickly, its electrical resistance drops. Out of habit - it seems like a paradox ... And just as quickly, its electrical resistance drops. Out of habit

- it seems like a paradox ... And just as quickly, its electrical resistance drops. Out of habit - it seems like a paradox ...

When an ionizer operates at the upper end of our "atmospheric generator", its resistance, relative to the atmosphere, also tends to zero. More precisely, it is negligible. Volumetric effect, as in the case of grounding in the ground. The strength of the current in the circuit depends only on the performance of the ionizer .. Convenient ...

No, we will not pile the burner on the upper end of the pantograph. And firecrackers - we will not. And we don't have a piece of a radioactive element. It's for the best, by the way... During discharge, in a gaseous environment, the electrodes lose weight. For every ampere-hour of charge flowing through the gas, about a cubic centimeter of electrode material is sprayed by the plasma. Its composition does not matter. There are no materials resistant to plasma chemistry ... At least put tungsten, even silicon, even graphite. Everything burns and oxidizes. Guessed? If you put a radioactive source on top, then atmospheric corrosion will quickly corrode it to holes and all the muck will be sprayed into the environment, settling around in a thin uniform layer. Do we need it? Live easier.

The expendable knob for the receiver of atmospheric current, on all lightning rods, put a simple, environmentally friendly iron. From it, except for rust, no harm. We, too, will not break away from the team ... How to make a banal piece of iron emit plasma ions into the air? There is such a way!

We consider the area of the soil, which is shielded from the atmospheric electric field by a pin, for example, twenty meters high. Yeah, this is the same pine tree that we appointed under the receiver stand. Pi multiplied by "er square", right? Here "er" is the radius of the platform and the height of the receiver. The result is 1256 square meters.

Now we find the area of the receiving electrode, under given conditions, sufficient to ignite a corona discharge on it in clear, cloudless weather. It's simple too. The field strength in the corona is about 30 kV/cm or 3 MV/m. The field strength over flat ground is 130 V/m. We consider the proportion ... Approximately 500 square centimeters of bare metal, a ball with a diameter of 12-13 centimeters, at the top, will already be surrounded by a weak cloud of ionized air molecules ... If you take a thinner rod, then the corona discharge around it will be proportionally stronger. Just?

Not just... The speed of movement of free ions in the air, at atmospheric pressure, is measured in centimeters per second. The top of the current collector will be enveloped by a sedentary cloud of lazily drifting ions, and the discharge will stabilize at the threshold of ignition. As it actually happens with any real lightning rod. Something, slowly, always leaks through it into the atmosphere, but this current is almost imperceptible. Its consequences can only be detected indirectly, by the unnatural smoothness of the metal surface. All the irregularities there seem to be polished. Really. The protrusions and burrs are the first to be "eaten up" by a quiet discharge. For a similar reason, grass is so evenly "trimmed" in all high-mountain "alpine meadows". The field of atmospheric electricity in the mountains is strong. On each blade of grass, sticking out a little higher than the rest, maybe, in bad weather, catch fire "

Conclusion? If you need a strong discharge, then you need a "point". Not simple, motionless, but dangling in the wind, blown by air pressure. Steel foil (ideally) or metallized paper, varnished from moisture. A long strip of such foil is now fluttering in the wind. Melting, melting, melting... Consumable! And the current adjustment is very simple - the position of the support. Tilt lower - the discharge field weakened. Raised higher - intensified. Need for inventions is cunning ...

Since the earth is negatively charged relative to the atmosphere, and the installation case is grounded, the voltage on the central electrode of the cement pipe is positive. Equal to the potential on the "receiver". When the process stops, this high-voltage part is closed to the housing with a grounded steel pin. Several tens of kilovolts are still present there. The simplest example of using an atmospheric generator "directly" as a ready-made power source for an "electrostatic precipitator". No matching devices for you, no converters. On one side of the chain, a corona discharge burns around an "electricity receiver" splashing in the wind, on the other, a corona discharge burns in a pipe through which dusty gas rushes from the reactor. From the central electrode (barbed wire) the ion flow pushes its way to the surrounding grounded walls. On the way, it charges cement particles and they drift there, after the discharge they settle on the metal. The pipe trembles as the cement slides down the spiral path into the hopper. And nothing else is needed. The "corona" sweeps the entire condensed fraction out of the gas like an invisible broom. It's very simple and clean, yeah... Adjustment of voltage and current - by tilting (lifting height) of the "receiver" bar. How much exactly the voltage in the circuit - no one knows. There were no people willing to measure. And why? You can see from the exhaust port of the pipe ... If the outgoing gas is clean of dust, everything works fine. As soon as the clubs appeared - lift the rack higher. The discharge does not cope ... And sparks of breakdowns began to click loudly in the iron pipe - lower it lower. On the way, it charges cement particles and they drift there, after the discharge they settle on the metal. The pipe trembles as the cement slides down the spiral path into the hopper. And nothing else is needed. The "corona" sweeps the entire condensed fraction out of the gas like an invisible broom. I came up with another idea for generating electricity from ionized air.
Man has long been able to receive electricity directly from the air. When we breathe, we do it. If we run fast, we consume more energy, and therefore we breathe more intensively.
How to collect ions in the air and get electricity?
It is possible to drive a stream of air through a strong magnetic field. Positive and negative ions will scatter in different directions, separated by a magnetic field. They should fall on the plates to which the current collector will be connected. For example, a capacitor. Only I need a person on the forum who will help to calculate this installation. To know at what speed it is necessary to drive air through the pipe through a magnetic field, what strength the magnetic field should be, the area of the plates on which the ions fall. How much energy is contained in a cubic meter of ionized air?<br /><br />-- Apr 20, 2013, 23:32 --<br /><br />I tried to conduct the experiment I mentioned above - the effect is zero. Those. using a magnet, it was not possible to separate air ions.
I bought two plate magnets, fixed them with adhesive tape between two metal plates. I tried two plates of copper, aluminum and experience when one plate is made of copper and the second of zinc (as in galvanic cells). I connected a multimeter in voltmeter mode to the plates. He showed a potential difference of zero point, horseradish hundredths of milliamps. I tried to blow on the plates so that air passes between them and blow on them also with the help of a fan - the effect is the same. It turns out that ions in a magnetic field will simply rotate in a circle, as in this model . To force the ions to be attracted to metal plates, you need to apply an electric field of several kilovolts to them, but then no perpetuity will naturally work, because. we will spend more energy than we get.

The only thing that successfully came to my mind about the implemented projects of "vechnyaks" was to use horsepower. After all, horses also breathe air, eat free grass and water.

Who has any ideas how to make ions from the air separate into positive and negative, so that positive ones fly to one plate, and negative ones to another, so that a potential difference is created between the plates?

Good afternoon.
I decided to conduct some experiments for myself regarding atmospheric electricity.
First experiment:
- galvanized sheet s=0.3mm, 2 sq.m.
- height 25m,

Max Rud
Anti-Tenturian

- grounding - galvanized sheet 0.3mm, 0.5 sq.m.
- between them a wire through a voltmeter.
Result: 0.5V maximum.
Thinking that a brick building with iron elements distorts the electric field, we decided to inflate the balloon and go out into the open field.

Here is a video of experiment #2.
[media]https://www.youtube.com/watch?v=iFk3zOwr1wQ[/media]
nothing works yet....
Now we think that we need to introduce a capacitor into the circuit. Perhaps there is an equalization of potentials, which we cannot even notice.
While like this

Thanks for the material.
Shot perfectly, the work is done, but there are a couple of errors.
1. The resistance of a household voltmeter is very low, and the current obtained in this way is small, which is why you did not manage to measure the voltage!

Well, here's an example for you, charge a capacitor with a small capacity (up to ten microfarads) and measure its voltage with your voltmeter. You will see that the capacitor itself practically does not discharge, but as soon as you touch it with a voltmeter, the voltage across it immediately drops ...

Therefore, you also need to put a capacitor in the circuit and measure the voltage on it, but not constantly, but only occasionally touching with a voltmeter.

2. Take a steel broom instead of a frame and aluminum. that is, a bunch of wires sticking out like a panicle on one side and soldered or wrapped with wire on the other. So the efficiency will be many times higher.

What was used as a rope for the ball? The wire? In isolation?

Rostislav , 4 April 2014 #5

Thank you very much for your comment and attention.
I think now an active lightning rod should be used as an antenna.

Max Rud
Anti-Tenturian

It ionizes the air around it.
We will reach the voltage, but then there will be a question with the current strength ...
But we have assembled the circuit. But not tested due to extremely low voltage.
Let's move on.

> Rostislav said:
>
> *What was used as a rope for the ball? The wire? In isolation?*

As a cable, there was a stranded wire 2mm.kv.

Max Rud , 4 April 2014 #6

Anti-Tenturian

The topic is interesting. I will share my observations.
During a thunderstorm, I observed several times how a discharge of a couple of centimeters jumps between a disconnected antenna cable and a nail in the floor. This was before the army. We had strong dry thunderstorms then in Altai. There is lightning, but no precipitation.
Somehow, after the repair, I took the plasma home for testing. Installed and hooked up all right. In the evening it began to rain and a thunderstorm approached. I decided to be safe, the device is a client, you need to pull out the antenna. When trying to pull out the antenna, I received a millimeter discharge between the antenna and the antenna connector. (Plasma turned out to be alive🙂) I bring my finger to the antenna cable and get a discharge. Reddish in color, about a millimeter long. Played for about five minutes.
Later I decided to conduct an experiment to connect a voltmeter between the antenna and ground and take measurements. Waited until the storm approached again. All day before the thunderstorm it was roasting for 30. I went to the service. Time of measurements is 22-23 hours. I quickly bungled an antenna of 11 m of an antenna cord with a section of 3 mm, a decrease of 5 m of a 75 ohm cable (the cable braid was not connected either from above or from the bottom), grounding was 1 ohm. The height of the suspension top point is 6 meters (attached to the ridge of the building), the bottom point is 1.5 meters. In general, an impromptu inclined beam turned out.
The device used a switch, if memory serves ts4341. The selected mode is DC measurement, the measurement limit is 2.5 volts. Installed the device. I turned the head of the device to the exact "0". I'm sitting waiting. Readings "0" Thunderstorm is approaching readings "0", even the arrow does not twitch at the time of the lightning strike. As soon as it started to rain, the device came to life. The readings are very small, so I connected the dt890 in parallel. The measurement limit is 2 volts. The voltage between the antenna and ground is constant 0.02 volts. I didn't measure the current. The alternating voltage is not fixed by the devices. (Maybe not, or maybe the devices are not like that). The switch circuit during lightning discharges reacted but not more than 0.3 volts. Perhaps the inertia of the device is superimposed. The digital camera did not record flashes at all. The storm front proceeded from the place of measurements in 8-10 km. I counted the time after the lightning flash and multiplied by 300. Later this experiment was carried out in the daytime at about 14-15 hours. The storm passed in 3-5 km. The voltmeter reading is about twice as high. I did not write down the exact data (a working

UNITED STATES PATENT OFFICE.

H. CHARLES VION, OF PARIS, FRANCE.

IMPROVED METHOD OF UTILIZING ATMOSPHERIC ELECTRICITY.

Specification forming part of Letters Patent No. **28,793**, dated June 19, 1860.

To all whom it may concern:

Be it known that I, HIPPOLYTE CHARLES VION, of Paris, in the Empire of France, engineer, have invented a new Mode of Obtaining Atmospheric Electricity and Terrestrial Electricity and its Industrial Applications; and I do hereby declare that the following is a full, clear, and exact description of the same, reference being had to the accompanying drawings, making part of this specification, in which—

Plate 1 represents a front elevation; Plate 2, a side elevation of an aerostat, in combination with certain other devices for obtaining atmospheric and terrestrial electricity; Plate 3, a plan of the device for obtaining terrestrial electricity; Plate 4, detached portions of the apparatus. Plate 5 shows a front view, and Plate 6 a vertical section and various details of the apparatus when applied in mountainous regions, the use of an aerostat being dispensed with.

The object of my invention is to form an electric pile of great power by using the positive electricity contained in the atmosphere, and the negative electricity contained in the earth, so as to make the electricity therein contained available for industrial purposes.

To enable others skilled in the art to make and use my invention, I will proceed to describe its construction and operation.

A is aerostat of a tubular form closed at both ends. It is made of suitable material, so as to be impervious to air. Its dimensions are such as to give it great ascensional power when filled with gas.

a a are valves in the surface of the aerostat, to be opened when the inflation of the aerostat should become too great.

A long india-rubber tube, I, communicates with the interior of the aerostat, being attached to the latter, near one end of its ends D, as seen in Plate 1, while the lower end of the tube I is attached to a gasometer, (not shown in the drawings.) The gasometer is to be fed with hydrogen gas, produced by the action of the pile itself, the negative wires of which (afterward to be described) enter a body of water at or near the base of the apparatus and decompose the water so as to produce the hydrogen gas. As the aerostat is supposed to be at a considerable height the tube I must be of corresponding length, and is constructed of a number of tubes, short wooden tubes I′ being inserted where the tubes I are joined, and a fastening-ring, I″, being slipped over each of the joints, as seen in Fig. 3 of Plate 4. At certain distances the tube I is fastened to the net-work of the positive wires (afterward to be described) in order to secure the tube against the action of the wind, and at each of these fastening-places a washer, I‴, is inserted in the tube in order that the tube shall not be compressed by the wire or other means employed to fasten it to the net-work of positive wires. (See Fig. 4, Plate 4.)

The aerostat is surrounded with a net-work of wires, one layer of the wires, C, being parallel with the axis of the aerostat and fastened to rings D at both ends of the aerostat, and the other layer of wires, B, extending partially around the aerostat at right angles to the wires C. One end of each of the wires B extends around an iron tube, E, some distance below the aerostat and meets the other end of it between the tube E and the aerostat. The two ends are fastened together by a ligature, B′. (See Fig. 1, Plate 4.) Each end of the tube E terminates into a ball, *e*. The wires B are fastened to the surface of the tube E by means of a helical wire, F, wound around the tube and across the wires B, as seen in Fig. 1, Plate 4. The upper ends of long vertical wires G are also wound around cylinder E, each wire G between two of the wires B, and the ends secured by a ligature, G′, as seen in Fig. 1, Plate 4. The helical wire F is also wound across the wires G, so as to keep them in their places on tube E.

The vertical wires G, which are to be the conductors of the positive electricity of the atmosphere, must be of a length proportionate to the desired efficacy of the electric pile, and the size and ascensional power of the aerostat must, of course, be adequate to sustain the weight of and keep suspended the wires G, (a weight still further increased by the horizontal cross-wires H, with which the vertical wires G are interlaced, in order to form a net-work not liable to be deranged by the action of the winds or similar influences.) The two outside wires, G, are stronger than the rest of them, and their lower ends are fastened to dynamometers of any suitable construction. These dynamometers are attached to the ends or a massive iron cylinder, J, and they serve to indicate the tension in the outside wires, G, and the corresponding ascensional power of the aerostat. According to the reading of these dynamometers the aerostat has to be supplied (through tube I) with more or less gas. The lower end of each of the wires G is wound around the cylinder J, and secured by ligatures similar to those above described. The wires G are all insulated (by a coating of gutta-percha or similar substance,) except where they are in contact with tube E and with cylinder J, and a similar insulating coating is laid on cylinder J, after the lower ends of the wires G have been fastened to it.

Another cylinder, K, similar to J, is placed at some distance from and parallel to cylinder J. It is connected with cylinder J by wires L, wound around both cylinders and interlaced with cross-wires M. The wire-work L M and cylinders are insulated (in a manner already described) against outside influences, so that the only electric communication between the two cylinders will be through the wires L. The two cylinders are placed upon insulated columns P. The cylinder K may be used as a substitute for cylinder J, and vice versa, whenever repairs become necessary. Insulated branch wire or wires are attached to the cylinders J K and wires L, so as to conduct the positive electricity obtained from the atmosphere by means of the above-described apparatus to wherever it is desired for industrial purposes. The insulated wires Q (interlaced with cross-wires R) are placed on the ground underneath and parallel to the positive wires L. Both ends of each of the wires Q are sunk into the earth or submerged in water, and fastened to a metallic plate coated with a metal not subject to oxidation. These wires Q are the conductors for the negative electricity of the earth, and a branch wire or wires attached to the wires Q serve to transmit the negative terrestrial electricity to wherever it is wanted for industrial or other purposes.

By uniting to the ends of the positive and the negative branch wire or wires a powerful electric current will be obtained, one pole of which is the atmosphere and the other the earth, and may be applied to any suitable useful purpose.

I will now proceed to describe the modification of the above-described apparatus when to be applied in mountainous countries.

P represents the positive electric copper or other metal wires coated over with an insulating substance. The upper ends of each of the positive wires is soldered to a prompter, O, at P′, Figs. 1, 5, and 6, Plate 6. The lower portion of each of the positive-wires is secured to an insulator, T, Fig. 2, Sheet 6. The positive wires are held above the ground by joints A, Figs. 3 and 4, Sheet 6, projecting from the soil at suitable distances from each other. The wires P are intended to follow the inequalities of the ground on which they are laid.

The prompters O, Figs. 5 and 6, Sheet 6, are iron rods sharpened to a point and silvered or coppered at their upper ends. The lower part of the prompter is fastened into a pole, S, covered with tar, which isolates the prompter and holds it in a firm position. A large metallic plate may be soldered to each prompter, as shown in Fig. 6. The positive wires may be soldered to the rod of each prompter or to the plate which is fastened thereto.

One or more branch lines, E, are soldered up to the positive wires to transmit the positive atmospheric electricity for which the wires P are the conductors to any desirable point.

N are negative iron or other metal conductors coated with an insulating substance. The upper ends of these wires rest on the ground near the positive insulators. The lower ends of these wires are soldered to a metallic plate or plates, V, Fig. 7, Plate 6, coated with a metal not subject to oxidation. The negative wires are sunk into the ground at very great depth or into wells, rivers, or into the sea. The negative electric branch wires are attached to the negative conductors N in the same manner as the positive branch wires are to the positive conductors. The branch wires and the soldering are coated over with an insulating substance. They are intended to carry the negative terrestial electricity to any desired point.

What I claim as my invention, and desire to secure by Letters Patent, is—

1. The peculiar arrangement of means herein specified, whereby I am enabled to use the positive electricity contained in the atmosphere and the negative electricity contained in the earth, and thus form an electric pile of considerable power and make the electricity therein contained available for industrial purposes, as set forth.

2. The combination of an aerostat and vertical wire-work with a tube, I, for admitting gas into the aerostat, in the manner and for the purposes above set forth.

CHARLES VION.

(57) **ABSTRACT**

A method of converting atmospheric electrical discharge to a useable form of energy by arresting, storage and retransmission of lightning induced electrical discharge is disclosed. The invention discloses methods of deploying this technology even in isolated locations where no electricity infrastructure exists. Additionally, the potential for achieving in excess of 1 GWe of electrical power supply at costs orders of magnitude lower than fossil fuel or solar is also disclosed. Isolated collection units are disclosed. A method of deployment of these devices on individual cars and recharge stations is disclosed which in effect unplugs these automotive and recharge stations from the grid. This capability significantly decreases their dependence on the electricity grid infrastructure, enabling a much more enhanced rollout capability for the industry. The concept of Energy Dams is disclosed. These are facilities with substantial electrical energy storage capacities with the capability of receiving energy feeds from various generation sources.

METHOD OF ATMOSPHERIC DISCHARGE ENERGY CONVERSION, STORAGE AND DISTRIBUTION

TECHNICAL FIELD

[0001] This invention relates to the field of electrical energy generation and storage in general and the conversion of atmospheric electrical discharge to a useable form of energy by arresting, storage and retransmission of lightning induced electrical discharge in particular.

BACKGROUND OF INVENTION

[0002] Lightning has always been a destructive force of nature. Causing death by electrocution and starting fires both in residential areas and in forests. In either case the loss of life and property is substantial. Lightning strikes have affected communication systems, and by uncontrolled arcing, electricity grids leading to loss of power with substantial economic loss

[0003] Lightning is the number one cause of forest and farm fires just in the United States and causes over 80 percent of all livestock losses due to accidents. Property losses run into billions of dollars annually and thousands of deaths and injury are reported yearly. Business losses from power and communications failure run into billions of dollars annually. Up to now, lightning strike damage has generally been controlled primarily by grounding.

[0004] A lightning discharge can have voltage of 10 MV to 100 MV and current of 1 kA to 300 kA. It packs so much voltage that it can leap a mile through the air and strike another object. Lightning can strike a building directly or leaping to it after striking a tree or other nearby object or by following a power line. It can strike any object that provides an easier path to the ground for it than the air. Because of the large network of lines, lightning can strike a utility pole at one point and be transmitted to any location in the network. Because of this, utility companies use multiple grounding and other protective devices per mile to ameliorate the lightning effects.

[0005] There has been a lot of activity in the alleviation of lightning damage but none in utilizing its energy potential.

[0006] U.S. Pat. No. 7,495,168 discloses a dipole lightning conductor which can gather electrical charges from the atmosphere during a thunderstorm, opposite to the polarity of the adjacent cloud on one side and induce a different polarity on the other end contacting the ground. When a sufficient potential difference is reached between the dipole and the earth, a dielectric breakdown occurs sending a large amount of earth charge to the thundercloud, inducing a thunderbolt.

[0007] In U.S. Pat. No. 6,012,330, Palmer discloses a method of inducing lightning strikes by shooting a stream of ionized water into a thundercloud and triggering electrical conduction through the ionized water column to the ground. In this invention, while ionized water is used, advantage is taken also of capillary wetting of conducting mesh cable at the tip of which is tethered a balloon of conductor coated Mylar. It is easier to float a balloon than to pump a column of water to any significant height.

[0008] In U.S. Pat. No. 6,320,119 Gumley discloses a capacitively coupled composite air terminal with sharp and rounded end components for voltage manipulation to minimize electric field ahead of streamers to minimize corona discharge.

[0009] Kato, in U.S. Pat. No. 5,280,335, discloses a compound lightning low voltage arrester with high energy tolerance for power and telephone lines comprising a spark gap is connected to a serial combination of Zinc Oxide arrestor and a non-inductive resistor. By cooperative execution between the spark gap and the Zinc Oxide arrester, the Zinc Oxide is chosen to be of a rating such that thermal breakdown does not occur before the spark gap ignition voltage is reached. The arrangement ensures reliable and predictable discharge and arrester survival even under multiple lightning strikes of close proximity.

[0010] Subbarao in U.S. Pat. No. 4,338,648, discloses a discharge counter and arrester current meter to determine arrester steady state current and the number of discharge events occurring during a thunder storm lightning arrester event.

[0011] Greenwald and Moses in U.S. Pat. No. 5,610,813 disclose a thunderstorm cell detection and mapping system for acquiring localized lightning strike information and identifying and locating active thunderstorm cells.

[0012] In U.S. Pat. No. 4,272,720, a method of differentiating between cloud-cloud and cloud-ground discharges is disclosed. Indicating discharge events with no accompanying lightning ground strike. This indicates that even in the absence of streamers, there is significant electrical discharge that can be converted and stored.

[0013] Weir and Nelson disclose in U.S. Pat. No. 7,033,406, a high energy density ceramic capacitor with energy capacity of 52 kW.h in 2005 cu.in, the equivalent of 1600 kW.h/m^3. Hansen in U.S. Pat. No. 6,078,494 discloses multilayer ceramic capacitors comprising doped barium-calcium-zirconium-titanate dielectric, the materials basis for U.S. Pat. No. 7,033,406. It is claimed to be characterized by high dielectric constant, high stability of capacitance value, long service life, low loss factor, high insulation resistance capacitance, low voltage dependence, and wide temperature range stability. Electrodes of base metal alloys from the group of Ni, Fe, Co or their alloys are claimed to be perhaps just as effective as noble metals containing gold, silver, platinum and palladium and may also contain Cr, Ti, Zr, V, Al, Zn, Cu, Sn, Pb, Mn, Mo and W.

[0014] Although the energy density capacity is not disclosed, it may be in the same range as U.S. Pat. No. 7,033,406 showing a path for storing the energy that can be extracted from lightning discharge.

[0015] U.S. Pat. No. 5,361,187, claims dielectric constant (k) of up to 19000 using similar group of dielectrics and processes. In U.S. Pat. No. 5,604,167 dielectric constant values of between 11,000 and 14,000 are disclosed by the same inventor with equivalent materials and processes.

[0016] Since these capacitors use standard powder processing technique, it can reasonably be expected that equivalent characteristics may be observed with naturally occurring doped silicates such as phyllosilicates for example, montmorillonite: $(Na,Ca)_{0.33}(Al,Mg)_2(Si_4O_{10})(OH)_2.nH_2O$, or cyclosilicates such as Benitoite —$BaTi(Si_3O_9)$ as base materials appropriately calcined and doped.

[0017] In U.S. Pat. No. 6,078,494 multilayer ceramic capacitors comprising doped barium-calcium-zirconium-titanate dielectric is disclosed. It is claimed to be characterized by high dielectric constant, high stability of capacitance value, long service life, low loss factor, high insulation resistance and low voltage dependence, and wide temperature range stability. Electrodes of base metal alloys from the group of Ni, Fe, Co or their alloys are claimed to be perhaps just as effective as noble metals containing gold, silver, platinum and palladium and may also contain Cr, Ti, Zr, V, Al, Zn, Cu, Sn, Pb, Mn, Mo and W. In U.S. Pat. No. 5,361,187, the inventors claim dielectric constants of up to 19000 using similar group of dielectrics and processes. In U.S. Pat. No. 5,604,167 dielectric constant values of between 11,000 and 14,000 is disclosed by the same inventors with equivalent materials and processes. Since these capacitors use standard powder processing technique, it can reasonably be expected that equivalent characteristics may be observed with naturally occurring doped silicates such as phyllosilicates for example, various grades of montmorillonite: $(Na,Ca)_{0.33}(Al,Mg)_2(Si_4O_{10})(OH)_2.nH_2O$, or cyclosilicates such as Benitoite—$BaTi(Si_3O_9)$ as base materials appropriately calcined and doped.

[0018] Although the technology to arrest lightning strikes has been around for at least a hundred years, this invention to harness and store that power has only become viable due to recent advances in super-capacitor technology which has made possible the fabrication of ultrahigh capacitance capacitors with very long lifetimes, high power, high energy densities and very fast charge and discharge rates.

[0019] Just as flood water, another destructive force of nature in times past was controlled by building dams, and from the dams eventually came hydroelectric power; and wind including thunderstorms has now been harnessed to generate electricity, this invention describes the technology to harness the power of atmospheric discharges including lightening storms to generate useable electrical energy.

[0020] This disclosure also introduces the concept of an Energy Dam. Facilities of substantial energy storage capacity capable of receiving energy feeds from various energy sources such as Solar, Wind, Thermal Power plants and Lightning. For example, during a thunderstorm, electricity generated by wind and lightning is collected and stored.

[0021] Lightning strikes every part of the globe but not uniformly. The regions with the highest historical concentration of lightning strikes are shown in FIG. **1***c*. These include Florida and the Gulf Coast in the Americas, the Equatorial Highlands of DRC, Rwanda and Burundi in Central Africa and the Monsoon Belt in Asia.

[0022] Except for the Americas, typically, these regions have very little electricity infrastructure. With the capability disclosed here, substantial reserves of electricity can be generated, stored and possibly traded.

[0023] In regions of epileptic electricity supply, disruptions in power do not necessarily translate into disruption in service. Since when power is generated, it is fed into these energy dams or local storage units for eventual use. Just as in water supply, the customer is not necessarily conscious of when the local water company is pumping water into storage tanks or local dams, in energy dams, the customer need not be conscious of whether or when electricity is being generated by the utility company because the power to his home is drawn not necessarily live from the grid but from the local energy storage units or energy dams.

BRIEF SUMMARY OF THE INVENTION

[0024] A method of harnessing atmospheric discharge and storing said energy in a useful form for subsequent use is presented.

[0025] Since the voltage of a lighting bolt can be as high as 100 MV, a methodology for safely channeling this discharge for storage is disclosed.

[0026] It is the also the object of this invention to present a storage medium in which an energy capacity of 1 MW.h in a volume of under 1 m^3 can be achieved.

[0027] It is also a further objective of this invention to show how lightening strikes on tall buildings can be harnessed to provide energy for the building either directly or fed into the grid.

[0028] It is also an objective of this invention to present a methodology for harnessing lightening, heretofore a source of power disruptions for electricity grids and converting it into a useable form of energy and feeding it back into the grid.

[0029] Since each electricity grid has a lightning suppression unit, a methodology for harnessing the impulse from these units from lightening strikes and feeding it back into the grid is disclosed.

[0030] a method of deploying a network of said storage units along a utility grid is also disclosed.

[0031] It is also the objective of this invention to disclose a method of modifying the storage units for single building deployment.

[0032] A method of deploying said storage units as vehicular charging centers even in locations not readily served by a utility grid is also disclosed.

[0033] A method of manipulating the direction and movement of the lightening bolt in open air locations and redirecting them to predetermined collection points is disclosed.

[0034] Lightning storms are some of the major causes of wild fires in the world. A method of redirecting the electrical discharges in any given space via a network of polarized and non-polarized collectors is presented. The discharges can be stored, fed into the grid or grounded.

[0035] A method for non-spontaneous discharge generation and storage is disclosed. And a method for adapting the methodology for electric automotive deployment is also disclosed.

BRIEF DESCRIPTION OF DRAWINGS

[0036] For understanding of the present invention reference is made of the accompanying drawings in the following DETAILED DESCRIPTION OF THE INVENTION. In the drawings:

DETAILED DESCRIPTION OF THE INVENTION

[0058] This invention describes a method of harnessing the electrical energy in atmospheric discharges, including, but not limited to lightning, storing said electrical energy and transmitting said energy for use. To this end, as an illustration, the preferred embodiments are represented in the drawings shown in FIGS. **2** to **15**.

[0059] Since lightning discharge voltages range from 10 MV to 100 MV with current of 10 kA to 100 kA, the technology challenge will be in mitigating the ultrahigh power which range from 100 GW to in excess of 10,000 GW. Although individual strikes last less than 100 μsec, thunderstorms usually last longer than 30 min. in any cloud formation and location. Indicating that the energy that can be mined from any location in a thunderstorm can run in excess of 50 GW.H. Enough energy for 500,000 homes consuming 1000 kW.h per month. At $100 per 1000 kWh, the revenue equivalent is $5 million per thunderstorm per location.

[0060] In solar energy generation, the cost of a 1 MWe rating PV panel is about $1 million. To achieve 1 GWe, the cost implications will be about $1 billion. In fossil fuel plants, the construction cost is approximately $1.3 million per MWe, putting the cost for a 1 GWe at ~$1.3 billion excluding fuel, carbon footprint, and other operating cost. Though thunderstorms are not continuous, with storage capability, the cost basis for an atmospheric discharge energy source will be several orders of magnitude lower than fossil fuel or solar of any architecture.

[0061] One embodiment of this invention is depicted in FIG. **2**. Lightning is collected at the air terminals **10**, **20** and transmitted through the conductor **30** to an arrestor **40** and on to the capacitor **50** where the electricity is stored. From which it can be extracted **60** at point of use or transmitted into the grid.

[0062] The degree of atmospheric discharge charge collection can be influenced by the metallurgical composition of the collectors. FIG. **3** illustrates the fabrication of the collector with different metals of varying conductivities and atmospheric and electrical stability. In this embodiment, metallurgical compositions for the various segments comprise Ti, Cu, Al. Other metals or their alloys can be used depending on the required properties and the locations of deployment.

[0063] In yet another embodiment of the invention as shown in FIG. **4**, a composite collector with opposite polarity air terminals **100**, **110** is used. The air terminals are isolated from each other by an insulator **120**. The negative polarity terminal serves to deflect and manipulate the charge to the positive terminal from which it is conducted to the storage unit **130**.

[0064] Another embodiment of the invention is illustrated in FIGS. **5** and **6**. In this representation, negative polarity collectors, **160** deflect the atmospheric discharge so that they do not reach the ground but are deflected for collection at a predetermined terminal **180** of positive polarity and thereafter storage **200**. A plan view representation of this embodiment is shown in FIG. **6**.

[0065] It is essential to mitigate the power of the lightning before storage. In one embodiment of this invention, a collection of varistors of various power capacities, linked in series **270**,**280** and **290** are connected in parallel in lines **1** to n, to achieve a desired capability as shown in FIG. **7***a*. The resultant power is stored in the capacitor **300**. An insulator or fuse **305** is placed at the end of the varistor chain to protect the capacitor **300** against over-current. In the event of overstressing, the dielectric or varistor is deformed and the excess current is grounded.

[0066] Each component of the power mitigation unit is any of the following configurations as shown in FIG. **7***b:* A ZnO varistor **312** connected in series with a non-inductive resistor **313** and in parallel with a spark gap **311**. The resultant current is further modulated through another ZnO unit **314** and resistor **315**. A cascade of this configuration could be adopted to achieve the desired properties.

[0067] Zinc Oxide has a relatively large band gap of ~3.3 eV at room temperature. The consequence of this large band gap includes, higher breakdown voltages, ability to sustain large electric field and high power and temperature operation. Because of this, ZnO is the primary component in varistors and in voltage suppression devices. Zinc Sulfide has a band gap of 3.5 eV for the cubic form and as high as 3.91 eV for the hexagonal form at 300K. While ZnO band gap can be tuned from between 3-4 eV by alloying with magnesium oxide or cadmium oxide, the co-processing of ZnO with ZnS of the hexagonal wurtzite form should provide electrical field and other operational advantages over ZnO alone.

[0068] Multilayers of ZnO and ZnS or as sandwich layers with each other with ZnO achieving 50-99.9 mol. % of each layer can be adopted to improve on the suppression properties of the single layer ZnO varistor as is shown in FIG. **7***c*. Said varistor comprising a ceramic base body **318** of multiple layers, terminal electrodes **316**, **317** and internal electrodes **319**.

[0069] Alloying of ZnO with metal oxides and nitrides of transition elements including W, Zr, Mo, Mg, Cr, and Ti may improve its band gap characteristics and improve its voltage response non-linearity. Tungsten, in the form of tungsten silicide has very unique crystallization characteristics, particularly in the presence of dopants such as phosphorus or arsenic. Upon post deposition anneal, the Si in the non-stoichiometric tungsten silicide (WSix) segregates to the grain boundaries and the film interfaces. The dopant atoms diffuse preferentially along the grain boundaries. When oxidized, it is the segregated silicon that is oxidized selectively. If the W is exposed to the oxidizing ambient of O_2/Ar or O_2/N_2 at temperatures in excess of 700° C., tungsten oxide WOx (x=3, or 1.5) is formed. It has no corresponding crystallographic orientation to the underlying tungsten silicide or metal, being in the form of an amorphous powder. The fabrication of multilayer varistors with ZnO and WSi_2/WO_3, SiO_2 should provide the flexibility of modulation of the effective grain sizes of the host material to within 0.5-10μ as the case may be. This precise grain size control provides corresponding modulation of the electrical properties including overvoltage suppression.

[0070] A schematic of the storage unit **320** is shown in FIG. **8***a*. A collection of capacitors **330** are connected in parallel to achieve a desired capacitance. A schematic of the cross-section of each capacitor unit is shown in FIG. **8***b*. The unit **331** with dielectric layers **332** is a multilayer capacitor comprising alternately stacked internal electrodes **335**, **336** connected to external electrodes **333**, **334**. The dielectric layers may be of uniform composition, or layers of different compositions optimized for flexibility in the modulation of desired electrical, physical and reliability properties.

[0071] Capacitance in excess of 1 kF/m^3 with energy storage capacity of 1.5 MW.h is reported as being possible by existing art. With compositional and manufacturing improvements disclosed here these benchmarks are expected to be surpassed making possible energy storage capacities of up to 1 GW.h. Sufficient energy for 1000 households consuming 1000 kW.h of electricity per month for one month.

[0072] Lightning storms are a major cause of wildfire. To address this, in yet another embodiment of this invention as represented in FIG. **9**, air terminals **360** are set up on a selection of trees and connected by a conductor **370** in a mesh array as shown in FIG. **10**. The impinging charge is transmitted through a conductor **380**, through a suppressor unit **390** and on to the storage unit **400**.

[0073] Utility transmission lines usually have lightning collectors along the length of the network. In this invention as demonstrated in FIG. **11** air terminals **440** deployed transmission poles **450** are linked by a polarized conductor **460**. At predetermined locations the impinging charge is conducted through a suppression unit **490** and thereafter into the storage unit **500**. The stored energy is periodically released into the grid.

[0074] In yet another embodiment of the invention, air terminals **510** are deployed on light poles **520**. The collected charged are modified and stored in a storage unit **540**.

[0075] In another embodiment, the air terminal/collection units are deployed on radio transmission towers. The charge could be stored individually at each tower location or linked in a network as shown in FIG. **13**. In either case, the stored energy be used at each individual location or fed into the grid **570**.

[0076] In the absence of a thundercloud, lightening flash can be generated by the modification of the natural bias between the cloud and ground. This is demonstrated in FIG. **14**, where a positively biased conductor **580** of height greater than nearest ground elevation or nearest structure. The increased elevation and bias facilitates cloud to ground discharge even when there is no active lightning storm. The incoming charge is isolated by an insulator **600** and stored in the storage unit **610**.

[0077] In yet another embodiment of this invention, a balloon of conductive material is tethered to a terminal via a mesh line of conducting material. The balloon captures cloud to cloud discharges which are transmitted down to storage. In yet another embodiment this tether line may be wetted by a conductive solution such as but not limited to salt solution to facilitate the discharge conduction.

[0078] Another embodiment of this invention is shown in FIG. **15**. In an isolated collection system as shown here, the air terminal **620** which may be biased or unbiased is connected to a collection/storage unit **650**, **660** respectively by conductor **640** and isolated by a dielectric or insulator **670**. Should the discharge exceed the capacity of the isolation, the isolation is bridged and the charge grounded. This isolated collection system is particularly useful where there is no utility grid, particularly in very remote and isolated locations.

[0079] This isolated collection capability enables deployment on individual houses and isolated farms. In electric automotive recharge stations, this capability enables the location of these facilities in any location even those not served by regular electricity utilities lines.

[0080] In isolated rural areas, the deployment of these isolated collection units enables the provision of electricity where electricity grid infrastructure is not available or practical. The storage units can be deployed in banks as the estimated anticipated usage dictates.

[0081] In another embodiment of this invention, the isolated collection unit is modified to be portable for deployment on automobiles. The charge in the storage unit is linked with the automobile's electrical power or storage unit. Alternatively, it can replace the power storage unit of the automobile for pure EV or hybrid cars. Additionally, it can unplug these cars from the grid. With the ambitious industry plans for electric or hybrid cars the infrastructure for charging these cars either in garages or charging stations is somewhat limited. The capability to both 'charge as you go' and unplug from the grid would expand the infrastructure significantly.

[0082] In yet another embodiment of this invention, the isolated collection unit is deployed on trains. This could be in commuter trains that directly fed from the grid, or long-haul trains to augment or replace the fossil fuel used.

[0083] It is understood that the presentation of these steps in this disclosure is not exhaustive. Only the preferred embodiments of the invention and but a few of the examples of its versatility are shown and described in the present disclosure. It should be readily apparent to those of ordinary skill in the art that the invention is capable of use in various other combinations, environments and applications and is capable of changes or modifications within the scope of the inventive concept as expressed herein. These changes and modifications may be made without departing from the spirit and scope of the invention as set forth in the appended claims.

1. A method of converting an atmospheric electrical discharge into a useable form of electrical energy comprising the following steps:
   - (a) Arresting the discharge via an air terminal,
   - (b) Said air terminal connected via a conducting unit to a power mitigating (step down) unit which can reduce the discharge voltage from approximately higher than 100 MV and 100 KA to below 20 kV, 10 kA.
   - (c) The step down unit connected to an energy storage unit which may comprise modules of high energy density capacitors
   - (d) Said storage units arranged such that the stored electrical energy can be discharged into the grid or to an appliance at point of use as desired.

2. A method of claim **1** wherein the arrestor and mitigating unit comprise an array of self-healing varistors in series and parallel chosen to ensure total conversion of the incident lightning discharge to a voltage/current level suitable for storage in said capacitors.

3. A method of claim **2**, where the power mitigation unit is any of the following configurations:
   - (a) Single ZnO varistor or
   - (b) Zinc Oxide arrester connected in series with a non-inductive resistor
   - (c) Zinc Oxide arrester in series with said non-inductive resistor and in parallel with a spark gap.
   - (d) A cascade of configuration as described in (c).

4. A method of claim **1** wherein the storage unit comprises modular array of high energy density doped ceramic capacitors with storage capacity of 10 kWe.h to 1 GWe.h and volume 0.1 to 1 m^3 and up to 1000 units as the desired capacity dictates.

5. A method of broad spatial lightning protection by the manipulation of the path of an electrical discharge via the manipulation of the air terminal bias magnitude and polarity Said arrestors being arranged in an array to achieve the redirection of the discharge path. The discharge path being directed to a collection unit at some location significantly removed from the initial discharge impact position.

6. A method of claim **5** wherein the discharge redirection is via a biased conductor to the said collection and storage unit.

7. A method of claim **5** wherein the area of protection is a forest whereby:
   - (a) A network array of air terminals is deployed on trees, in close proximity to said trees with tip approximating the treetops, or girding the trees to redirect the discharge along a biased conductor to a collection unit for the purpose of mitigating lightning induced fires.
   - (b) Said discharge electrical energy being stored or fed into the electricity grid.

8. A method of claim **1** wherein the discharge collection is on electrical power lines and the stored energy is fed back into the grid.

9. A method of claim **1** wherein the discharge collection and storage are at telecom towers, light poles or other free standing structures. Said storage being at individual collection sites or some location serving an array of collectors and said stored energy used for individual structure's operational energy need or fed back into the utility grid.

10. A method of non-spontaneous generation of atmospheric discharge by the following:
    - (a) Modulation of the magnitude and bias in a dipole air terminal relative to the ground
    - (b) Conductive material balloon tethered by a conductive mesh cable.
    - (c) Said cable being soaked by an ionic liquid, including, a salt solution to facilitate said atmospheric discharge conduction.

The discharge thus formed is stored for feeding into the greed or for operation as a stand-alone energy dam.

11. A method of claim **1** in which the discharge collection unit is configured as a mobile unit. Said unit being deployed on an automobile or any mobile platform. The said deployed unit extracting electrical charge from the atmosphere and storing such energy in a deployed storage unit on the said automobile. The energy thus stored, feeds the car battery which obviates the need for recharging at charging centers or from the grid.

12. A method of claim **1** wherein the electrical discharge energy collection unit is a stand-alone unit comprising modular capacitors configured as an electric vehicle charging station.

13. A method of claim **1** wherein the air terminals are deployed on buildings and the discharge energy collected thereby are:
    - (a) Stored and fed back into the grid.
    - (b) Stored for use by each building
    - (c) Stored in a central energy storage facility for use by the community in general.

14. A method of claim **1** wherein the said storage units are underground.

15. A method of claim **1** wherein the storage unit is of capacity and configuration to accept energy feeds from multiple electricity generation sources: Thermal, Hydro, Solar, Wind and Lightning.

16. A method of claim **4** wherein the storage unit is integrated into a Utility's Switch Farm.

17. A method of claim **4** wherein the multilayer ceramic capacitor unit comprises dielectric layers of varying compositions individually or as sandwich layers with each other containing Barium-Titanate silicates as host material doped with Zr, WSi_2/WO_3 to modulate grain growth to between 0.1 to 10 μm as the case may be; said modulation providing corresponding control of electrical and reliability properties.

18. A method of claim **1** wherein the varistor comprise multilayers of ZnO and ZnS individually layered or as sandwich layers with each other with ZnO achieving 50-99.9% of each layer; said layers being alloyed metal oxides of transition elements including W, Zr, Mo, Mg, Cr, Ti to improve voltage response non-linearity.

UNITED STATES PATENT OFFICE.

WILLIAM HENRY WARD, OF AUBURN, NEW YORK.

IMPROVEMENT IN COLLECTING ELECTRICITY FOR TELEGRAPHING, &c.

Specification forming part of Letters Patent No. 126,356, dated April 30, 1872.

I, WILLIAM HENRY WARD, of Auburn, in the county of Cayuga and State of New York, have invented an Electrical Tower for Accumulating Natural Electricity for Telegraphic Purposes, of which the following is a specification:

My invention consists of a tower for the purpose of receiving and imparting natural electricity, so as to be in constant contact with that upper stratum of electricity which surrounds the earth, by tapping which a never-failing supply is formed when brought into contact with the earth, as will be more fully explained hereinafter.

In the accompanying drawing, Figure 1 represents a side elevation of my improved electrical tower. Fig. 2 is a vertical central section of the upper part of the same. Figs. 3, 4, 5, 6, and 7 are detached views of several parts of the same.

The tower is constructed in three separate sections, a lower, a middle, and an upper one, and is placed on elevated mountain tops or peaks. The lower one, A, is a mere shell, having a door, *a*, and is constructed of any material suitable for the purpose. It is insulated from the middle portion B by means of a glass diaphragm, *c*, held between similar diaphragms of rubber, *d*, and of gutta-percha, *e*, by means of flanges *a'* and *b'*, formed on the upper end of the lower portion and the lower end of the middle portion of the tower respectively. These flanges are secured to each other by insulated bolts *f*. The middle portion B is provided with suitable openings or windows, G, having shutters or slats *g* pivoted in them, so that, by means of raising or lowering rods *h*, suitably connected to said shutters, the openings G may be shut or opened. A projecting roof, H, is formed on or secured to the middle portion B just over the openings G, and which serves the double purpose of protecting the said openings from the effects of the weather, such as rain or snow, and also for receiving the aerial electricity, which may be drawn from it by wires *i*, for land-line purposes. Above this roof H the middle portion of the tower is again insulated by diaphragms of glass, rubber, and gutta-percha from the upper portion I of the tower in the same manner as it is insulated from its lower portion. A circular plate, *j*, secured on the inside of this upper portion, bears a short tube, J, which is surrounded by the tube K of the ventilator L, from which latter the vane M extends; or the tube J may be held by rods extending from the side of the tower centrally. This ventilator is supported by a rod or shaft, *k*, firmly attached to the tube K, and having its lower bearing in a step, *l*, on a brace, *m*, crossing the middle portion B of the tower just above the openings G. This rod or shaft *k* is formed in two parts, insulated from each other, as shown at *k'*. On the lower portion of this shaft *k* is keyed or otherwise secured a sleeve, *n*, from which a horizontal serpentine cam-plate, *o*, shown in detail in Figs. 4 and 5, extends, over the rim of which the forked ends *p* of rods *h* seize, and which is so arranged relatively to the vane M and the shutters or slats *g* that the revolution of the vane by the wind will open the windward and close the leeward shutters or slats *g* and openings G by means of the rods *h*. Guide-plates or their equivalents N, provided with suitable openings, through which the rods *h* pass, keep the upper forked ends *h* of the latter in constant contact with the cam-plate *o*, which raises or lowers the rods, and consequently opens or closes the openings G as it revolves. A circular roof, O, extends from the tube K of the ventilator so as to cover and protect the open upper end of the tower. The upper portion I of the tower is provided with an insulating-tube, *p'*, through which a copper wire, *q*, enters the portion I of the tower, and is coiled around the tube J just under the tube K, which wire may connect that upper portion of the tower with any land line of wires. The upper portion I of the tower, as well as the tubes J K, may be constructed of zinc, while the vane may be made of zinc, copper, or any equivalent material, which, with the zinc and the moisture of the atmosphere, would form an electrical current. As the vane revolves it opens the openings to windward and closes those to leeward, thus helping to drive an aerial current of electricity into the insulated middle portion of the tower, which current passes upwardly through the upper portion of the tower and out through the ventilator or the top, which is swung around by the wind or aerial electrical current, thus forming a draught in addition to the closing of the shutters or openings to leeward, by means of which draught the electrical current is forced upwardly and out at the vane. The top portion of the tower is of course completely insulated from all below it, including the revolving central ventilator-shaft. As the middle portion of the tower allows the electrical current of atmosphere, wind, &c., to pass within, up, and out at the top it forms a continuous current, whereby the tower is receiving continually fresh and new supplies of electricity, which can be drawn from the projecting roof H by the wires *i* for the use of land lines of telegraphs or for other purposes, such as light, heat, &c. By the use of aerial electricity I entirely dispense with artificial batteries, forming my circuit merely by connecting the aerial current with the earth current. For instance, to bring Buenos Ayres, in South America, into direct connection with New York, the following plan would be pursued: One electrical tower is erected on Pike's Peak or any other suitable high mountain in North America, and another similar tower on some suitable peak of the Andes in South America. The former would, by means of land-lines, be connected directly with Denver, which place is again connected with all the prominent cities of the States. In a similar manner the southern tower is connected by land-lines with the prominent cities via Quito. New York telegraphs to the tower on Pike's Peak, and the operator having connected the land-line with the aerial current, the signals are transmitted through the aerial current to the tower in the Andes in South America, and from there—the land-lines being suitably connected with the aerial current—to Quito and Buenos Ayres. In this manner a message would be sent entirely by natural electricity in place of artificial. In the same manner a message may be sent across the ocean by having a high tower on each continent, each of which towers would have to be, of course, through land-lines connected with the earth to enable the ground current with the aerial current to form a circuit. Different towers may be erected on the different continents, and if they are all what is technically called hooked on—that is to say, connected to the earth—a signal given at one tower will be repeated at all the towers, they being connected with each other by the aerial current. If the earth-connection is severed, or the insulation with the tower destroyed, there is no power; but by insulating the tower and concentrating its force to a point, bringing the same corresponding effect from the earth current in connection, an exceedingly powerful electrical force is created.

Having described my invention, I claim—

1. A tower constructed so as to collect, hold, distribute, and utilize aerial currents of natural electricity for telegraphic and other purposes, essentially as described.

2. A tower for collecting aerial currents of natural electricity, constructed of three sections, insulated from each other and the earth, or their equivalents, substantially in the manner described.

3. In an electrical tower, the combination of the shutters or slats *g* with the ventilator-vane in such a manner that the vane, through suitable mechanism, always opens the shutters to windward and closes them to leeward, substantially as described.

4. In an electrical tower, the collecting, distributing, and protecting roof H, substantially as and for the purpose described.

5. The combination of the tube J and ventilator L with its vane M and the coiled wire or small cable *q*, substantially as and for the purpose set forth.

6. The combination of the insulated shaft *k* and rods *h* having forked upper ends *k'* with the shutters or blinds *g*, serpentine cam-plate *o*, and ventilator L, substantially as and for the purpose described.

The above specification of my improvement, being a tower for accumulating natural electricity for telegraphic purposes, signed this 29th day of June, A. D. 1871.

W. H. WARD.

GREEN GUIDE

Capturing free atmospheric electricity: Feasibility and challenges

Earth's atmosphere is in itself an infinite storeroom of energy. The regular diurnal variations of the Earth's electromagnetic network produce strong electric currents on a gigantic scale. The Earth has its own negative electr while the atmosphere is positively charged. The electric potential increases with the altitude, hence the electric for proportional to the atmospheric altitude. In the present times, where alternative energy holds the key to the energ crisis, the abundance of this source of energy has attracted the researchers' attention. Evermore exciting is its free availability in air and clouds. There have been efforts to capture it since long but a considerable success is still har come by.

Atmospheric Electricity, nature lends it for nothing:

All atmospheric electricity is a result of the potential difference between any point on the surface of the negatively charged earth and the other in the positively charged air above it. Earth's electromagnetic network consists of thunderstorms, the electrification of the air in a combined or uncombined state and the polar Aurora effects. Equa experiences more of thunderstorms than anywhere on the entire planet. These thunderstorms express themselve the form of lightning and atmospheric pressure, wind levels, solar winds and the solar particles. Estimates reflect t lightning strikes somewhere on the surface of the Earth about 100 times every second.

Secondly, the Polar Aurora provides a great natural spectacle and is an outcome of the atmospheric electricity. Ear magnetosphere abounds in profuse solar-wind-transferred-energy, which is visible from the polar regions of the p

Moreover, this simple, robust and low cost electricity is much cheaper than wind turbines. You don't have to count the weather conditions, and it's available day and night. No doubt, it's in abundance at the poles but that doesn't d its presence elsewhere.

Feasible ways to capture it:

Capturing Atmospheric Electricity means to exploit the natural electrostatic potential gradient of the Earth. The electrostatic potential gradient between the Earth and the ionosphere is about 100Vm-1 near the surface in summ and 300Vm-1 in winter. Electrically charging a bank of capacitors or operating an electrostatic motor/parametric conversion machine are some of the possible ways to convert this static atmospheric electricity into conventional Alternating Current.

The total energy contained in wind is 100 times the power used by all of human civilization. If we could tap into just 1 percent of that energy, scientists say it still wouldn't produce a major adverse effect on the environment.

The jet stream is made up of several large currents of high-speed air that rush eastward through the upper atmosphere. Six miles high, the winds have exceeded 300 mph.

A loop of kites attached to a cable would generate power as it moves continuously, pushed by high-altitude winds.

A helicopter-like wind machine would use four or more rotors to generate electricity, up to 240 kilowatts.

A wind generator held aloft by a helium balloon would fly 600 to 1,000 feet high, tapping into the brisker winds just above the ground. It could generate about 10 kilowatts, enough to support a Third World village of 250 people.

Wind-blown kites would drive a rotating turntable just as falling water turns a turbine in a hydroelectric plant.

Image Source: SFGate

1) Tapping the Jet Streams:

The jet streams generally blow at speeds up to 310 mph over the northern hemisphere and are a possible source atmospheric electricity. If the researchers could succeed in tapping these ferocious winds, the world's entire electr needs can be met. Scientists believe that a kite-like wind-power generator, lobbed into the upper atmosphere to capture the power of the jet stream, can produce energy, which is transmittable to Earth via aluminum or copper or invisible microwave beams. Next step includes its storage and transmission to target consumption points. The energy generation via the jet streams involved the inclusion of the designs enlisted below:

a. Ladder Mill: Rowing against the high-altitude winds, kites attached to a cable could generate a sizeable amount power.

b. Rotor Kite: A unique machine design includes more than four rotors to generate electricity, up to 240 kilowatts

c. Rotating Kite: The concept lies deep-rooted in conception of a wind generator at 600 to 1,000 feet. A helium ba keeps the kite in the air. The proposed electrical generation is about 10 kilowatts.

d. Turntable Kite: Though no data on the projected capacity is available, a rotating turntable still ensures better p generation.

2) Through Aerostats, as suggested by Dr. Plauson in 1920:

Dr. Hermann Plauson, the director of the Fischer-Tropsch "Otto Traun Research Laboratories" in Hamburg, Germa during the Weimar Republic of the 1920s, drew on the aerostats made from magnesium-aluminum alloy. Some electrolytically deposited needles, further doped with radium, perforated the aerostat all through it. Patched with amalgam, the aerostat went on to produce 0.72kW and 3.4kW 300m above ground level. The power could further increased up to 81-1/2 kilowatts in 24 hours by using two balloons with a special condenser battery.

3) The Pyramidal Electric Transducer:

Inspired by the Great Pyramid of Giza (GPG), a Californian researcher, Peter Grandics says that pyramidal horn antennas suitably detect the short-pulse waveforms. Fed by the hypothesis, a pyramidal antenna, modeled on the can transfer the electrostatic discharge into a resonant circuit. While coupling into the atmosphere, it effectively converts the random impulses into an alternating current. Resultantly, it has the potential to utilize the renewable electric power.

Remarkable technology has some obstructions:

Moreover, this simple, robust and low cost electricity is much cheaper than the wind turbines. You don't have to c on the weather conditions and it's available day and night. Frequent use of this technology will definitely lead to th discharge of storm clouds and the risk of lightning strikes will get minimized. No doubt, it's in abundance at poles that doesn't deny its presence elsewhere.

Despite it's being a feasible energy source, there are certain hitches scientists need to deal with:

I. As this technology makes use of tethers, it's hazardous to aircraft. On the contrary, you can't compromise even tether's thickness since density means more output. As a direct consequence, it necessitates bigger balloon size a more maintenance.

II. Like the airplanes, the balloons are also defenseless when it comes to bad weather. So, as is the case with wind solar power, adverse weather conditions play a role here also.

III. At 200 meters or above altitudes, the amassed charge goes far beyond the wires' potential. It requires electrica insulation around the wire to avoid the energy loss.

IV. After you've exploited the device for quite sometime, the electrical potential goes down drastically. It further hu the ionization capability of the device. Therefore, it requires extending of the surface electrical field via the use of thin wires.

MY FATHER

PREFACE

The fascinating science of electrostatics was developed mainly in the 18th century at a time when the technology and industry were too primitive to put this science to practical uses. As a result, serious research in electrostatics soon lost its momentum and, except for a few isolated efforts, was practically nonexistent during the entire 19th century. Only very recently practical aspects of electrostatics began to make their impact on the industry and economy, and the once glamorous but long forgotten science has again appeared at the focal point of serious scientific investigations.

A peculiar obstacle stands, however, in the way of many such investigations: because of the one and one half century of neglect of electrostatic explorations there is a singular lack of easily available quantitative and qualitative information on even the most basic electrostatic phenomena, techniques, and devices. Whereas experimental and theoretical data pertaining to most modern sciences are well documented and are easily retrievable from numerous reference sources, many data in the field of electrostatics must be extracted through thorough and laborious firsthand studies of old books and magazines, the very existence of which is not generally known, and which are not readily available in any of the present-day libraries or repositories.

It is precisely this kind of obstacle that the author encountered, when several years ago he started his research on electrostatic motors. Luckily, however, the obstacle soon transformed itself into a highly rewarding experience of studying various "ancient" books and periodicals and searching through electrostatic inventories of various European and American science museums. In the course of these studies he found numerous forgotten publications on electrostatic motors and found that several old electrostatic motors can actually be seen in some of the museums. (It is interesting to note that the latter motors are usually not on public display, apparently because of a lack of adequate information about their purpose and mode of operation available to museum personnel. It is also interesting to note that certain types of electrostatic motors were frequently employed in various animated toys during the second half of the 18th century, and that, although some of these toys are shown in museums, they are usually shown without an explanation of what made them move or how they were supposed to function.)

The purpose of this book is to describe the various types of electrostatic motors reported in the scientific literature between 1700 and the present, and to discuss in general terms their various design features and principles of operation. The book is written for a wide circle of readers, and care has been taken to avoid technical details that would be useful only to a small group of specialists. The readers interested in additional scientific and technical data on the various motors are referred to appropriate original publications cited in this book.

The material is presented in several chapters, each chapter describing a particular class of motors. The sequence of the chapters corresponds to the chronological order in which the earliest motor belonging to each particular chapter was invented. The sequence of material in each chapter is normally arranged also in a chronological order. The last chapter describes some of the most recent research results on electrostatic motors and extrapolates these results into the immediate future.

The author is grateful to his wife Valentina for typing the manuscript and for otherwise helping him to make the book ready for publication. He is also grateful to Dr. David K. Walker for reading the manuscript and for drawing the illustrations for the book.

11. Index 120

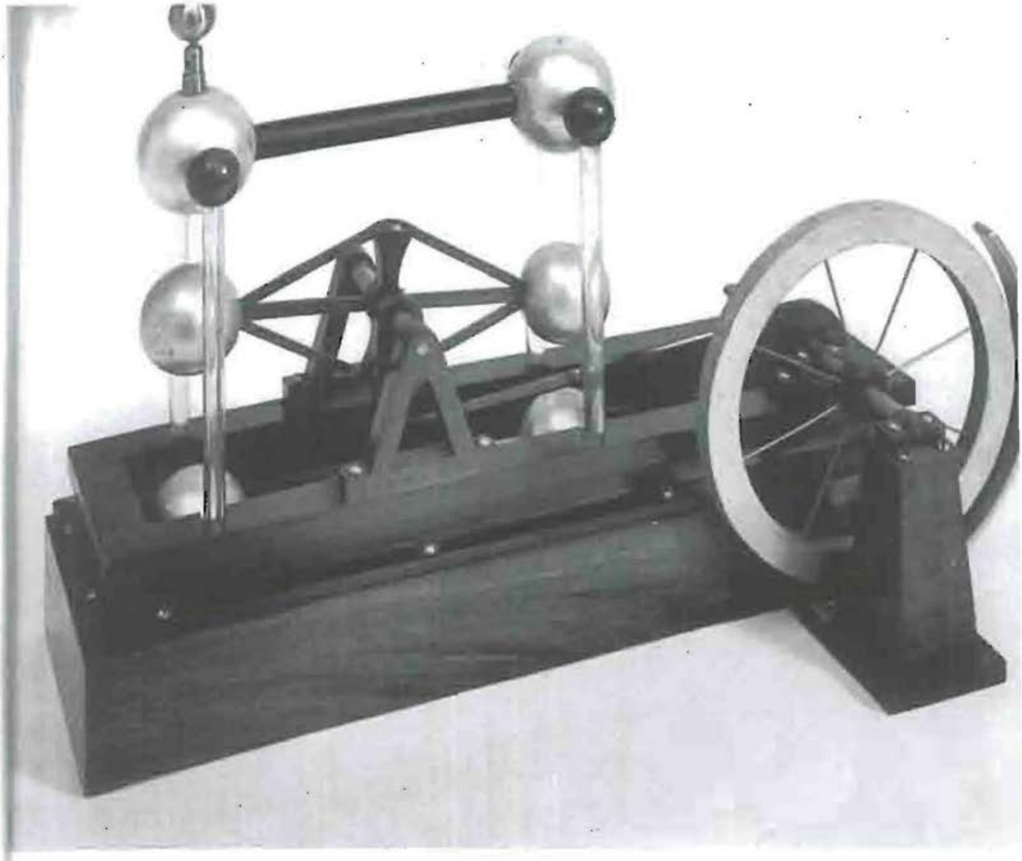

PLATE 1

Here is what H. B. Dailey wrote about this electrostatic motor which he and his father built in 1880: "Whether or not there is about the instrument and its history that which would ever give it a claim to any measure or serious interest, it is at least an electric motor most unique. A motor without magnetism, wiring, or any iron in its make up. A motor that runs by the action of the direct push and pull of the pure unconverted electricity itself".

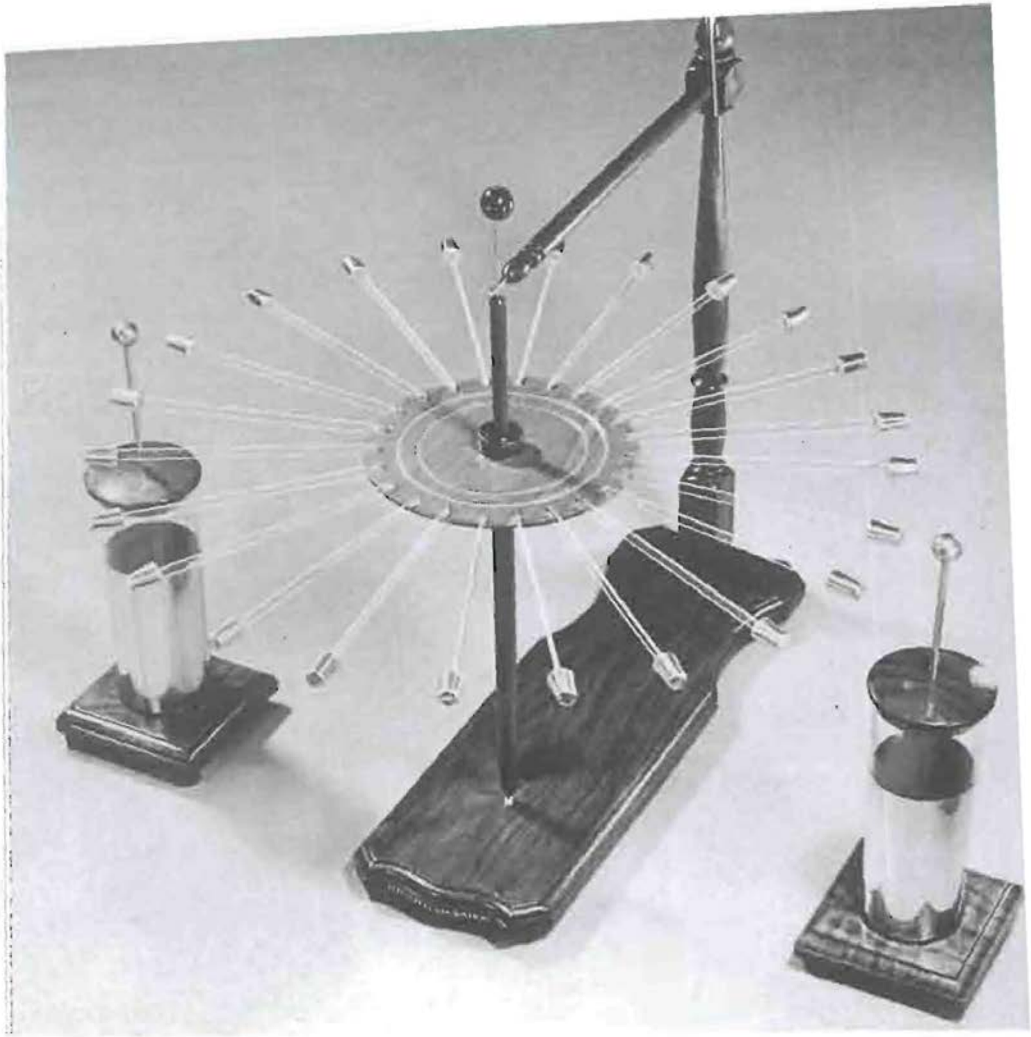

PLATE 2

It was Benjamin Franklin who in 1748 constructed the first electrostatic motors. No original drawings or models of his motors are known to exist, but his first motor must have looked very similar to this replica designed by the author for the Electret Scientific Company.

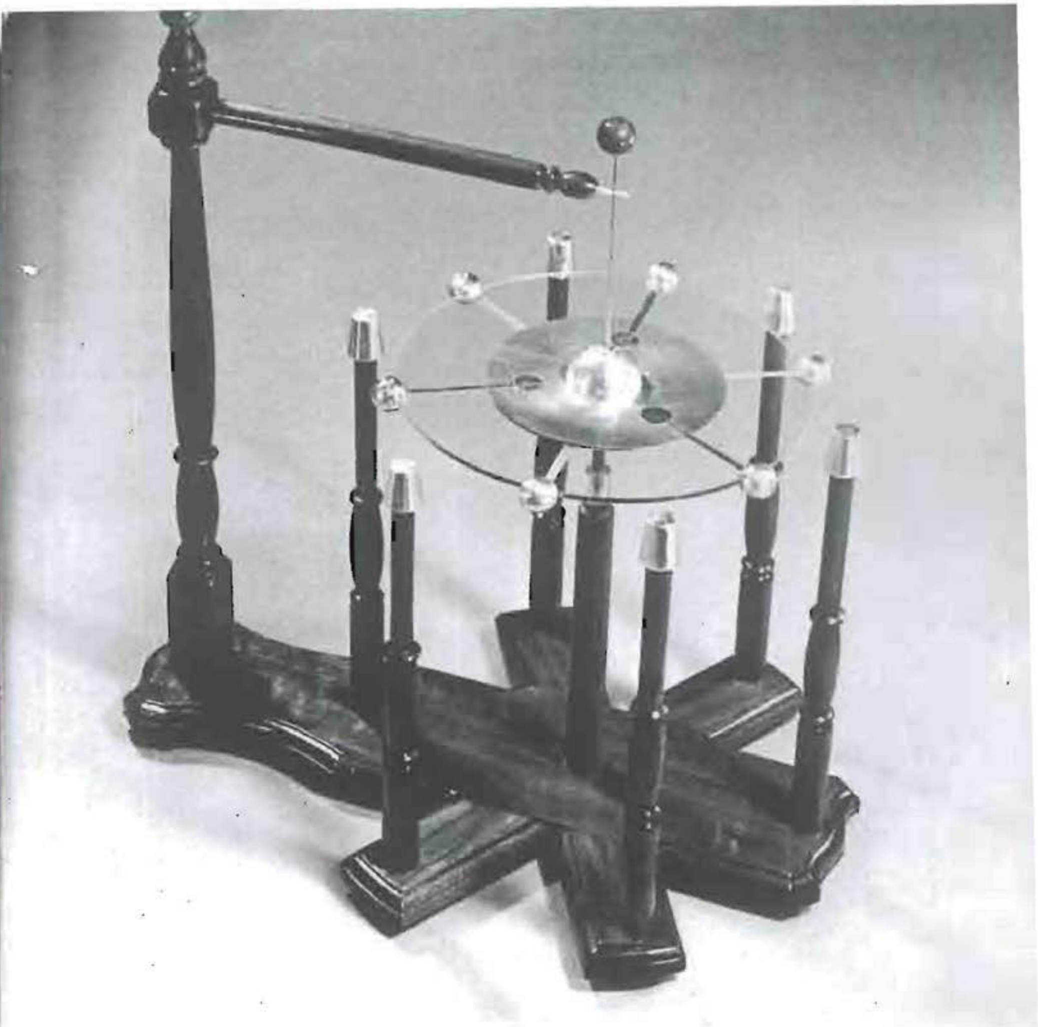

PLATE 3

Franklin's second motor probably looked very much like this replica also designed by the author for the Electret Scientific Company. Whereas the first motor operated from the electricity stored in Leyden jars, this motor operated from the electricity stored in the motor itself.

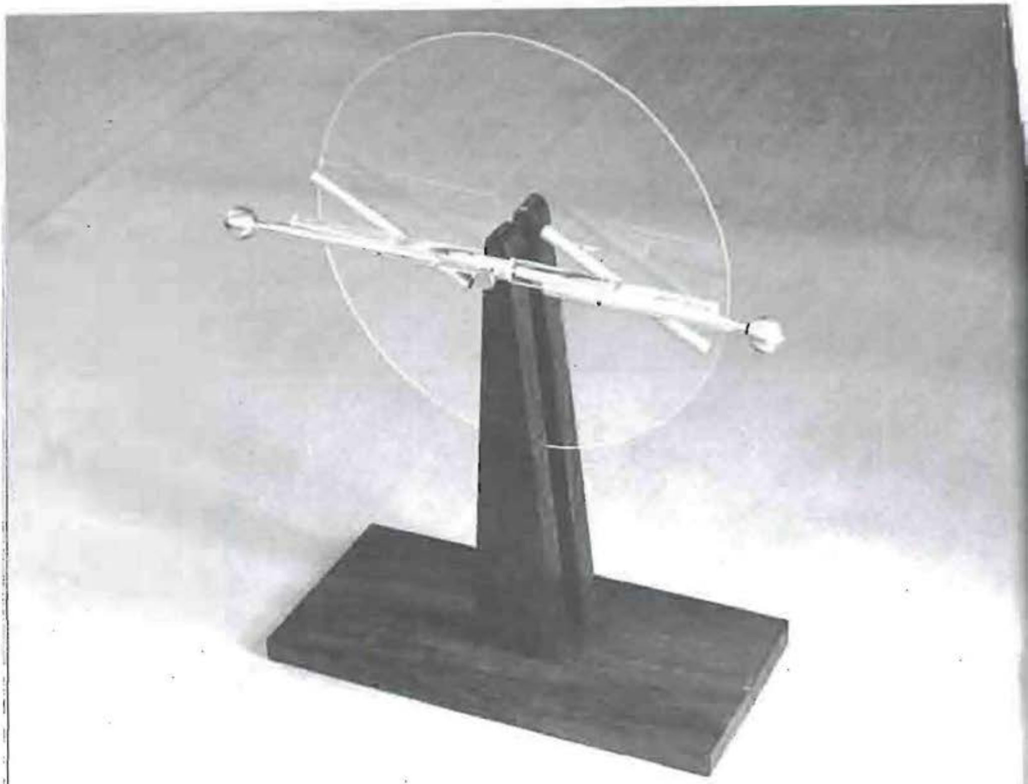

PLATE 4

The first corona motor was designed around 1869 by the German physicist Poggendorff. Poggendorff made a thorough study of the motor, but failed to appreciate its possibilities in the mistaken belief that no sources of electricity could supply enough power to any electric motor to make it do useful work. This simplified version of Poggendorff's motor was built by the author.

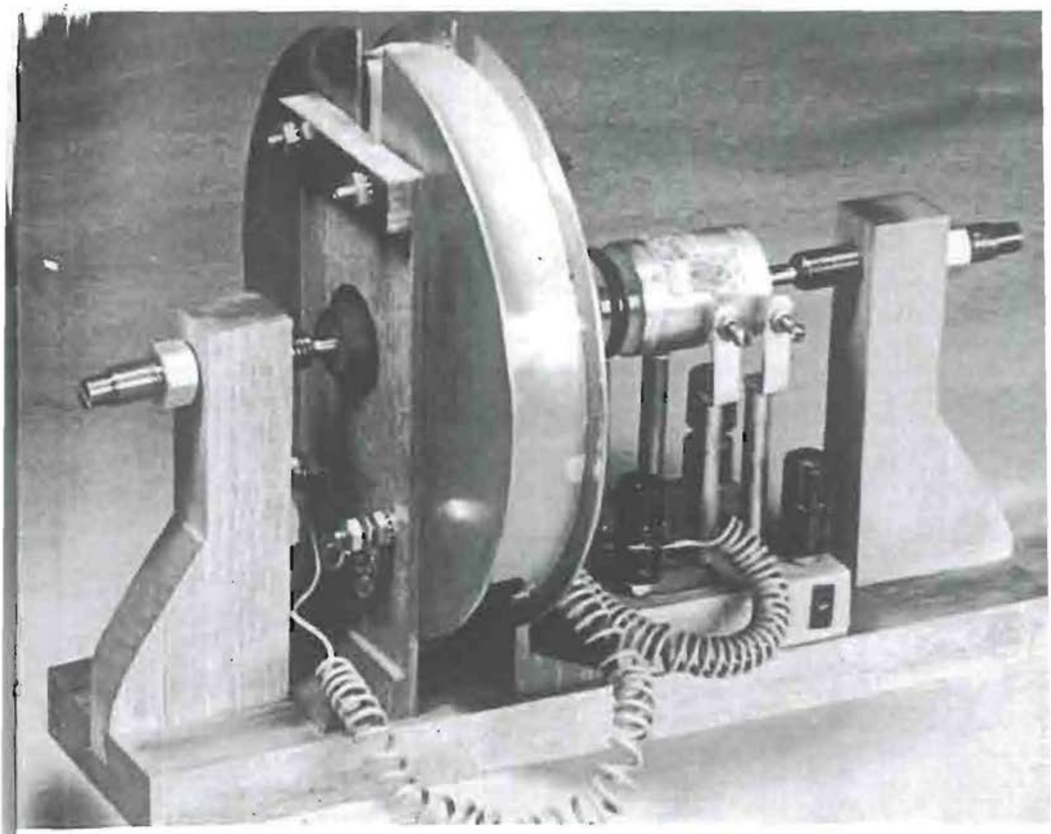

PLATE 5

The electret—a permanently electrized dielectric—is essentially a product of the 20th century. When an electret is placed between slotted electrodes to which a voltage is applied, the electret experiences a force. This motor designed by the author utilizes the slot effect. The rotor of the motor is a carnauba wax electret made of two oppositely polarized half-disks. The motor was built in 1966.

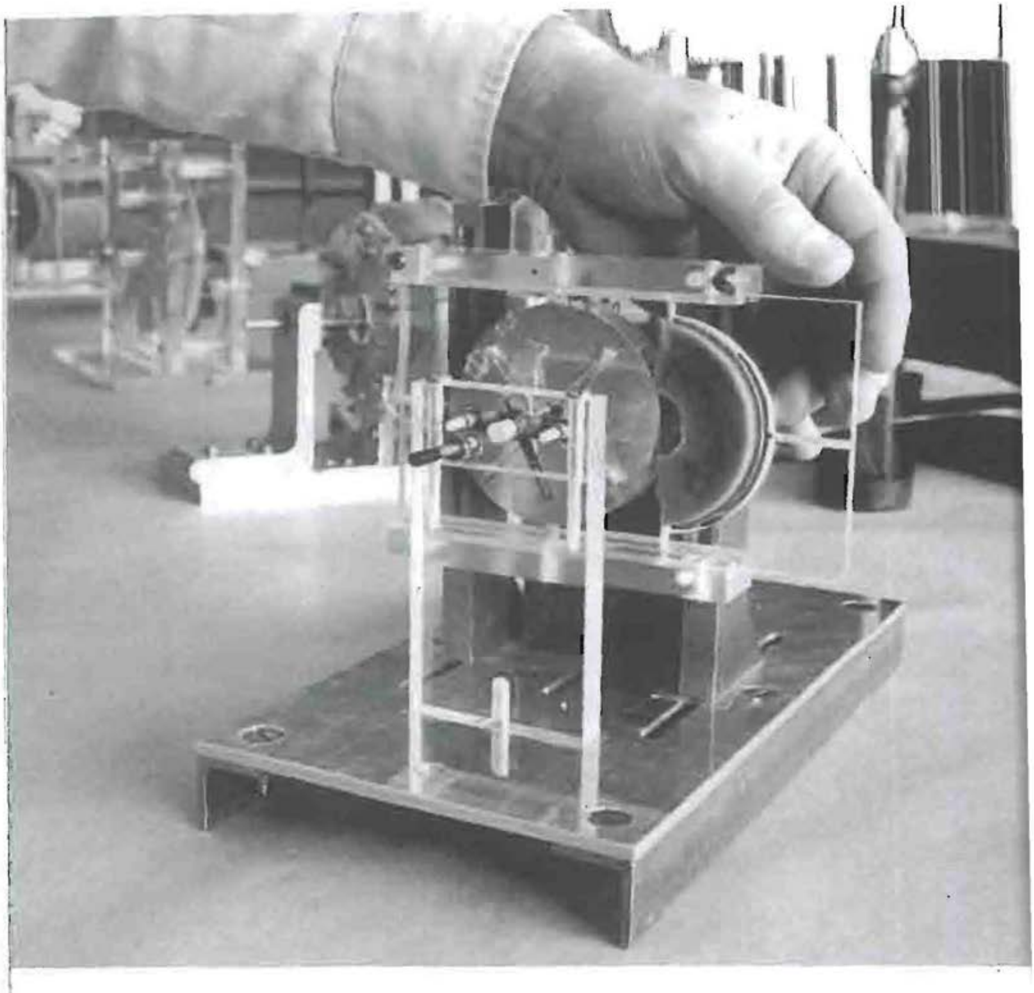

PLATE 6

A more practical design of an electret motor incorporates stationary electrets and rotating electrodes. The electrets can be easily withdrawn from the motor for servicing or replacement. The motor operates from approximately 60 volts dc. This particular motor was the first ever operated from atmospheric electricity.

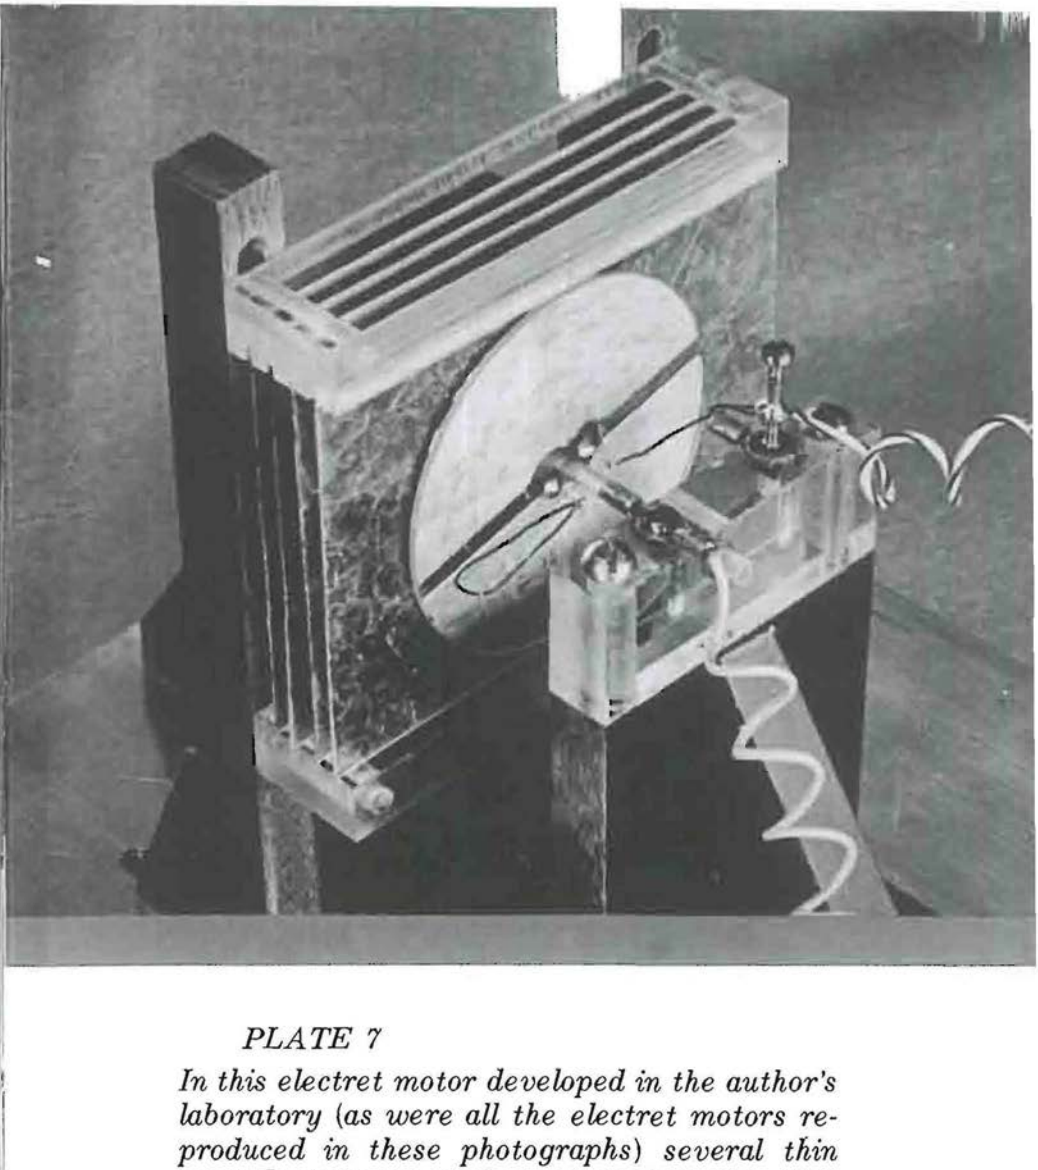

PLATE 7

In this electret motor developed in the author's laboratory (as were all the electret motors reproduced in these photographs) several thin mica electrets are used as active elements. This arrangement of electrets makes good use of the available space and allows one to construct relatively powerful electret motors.

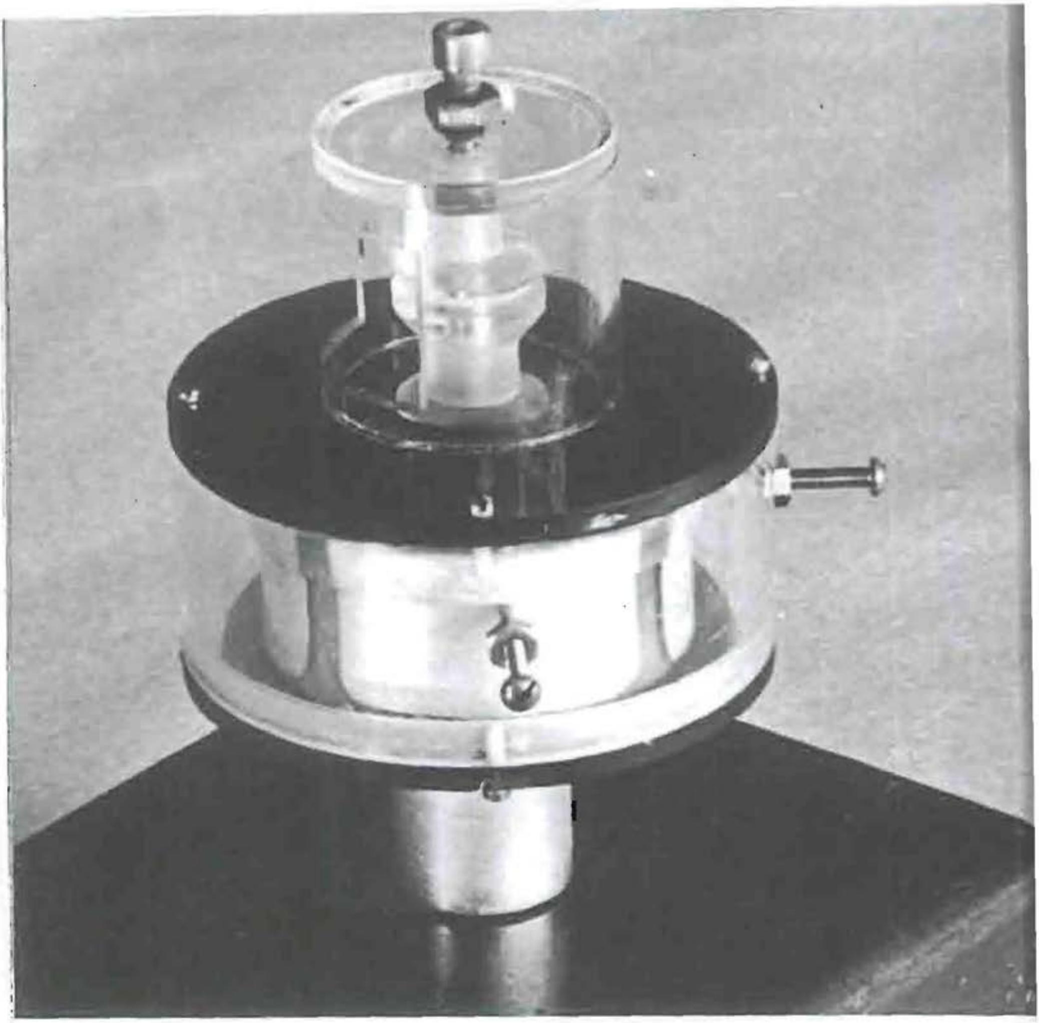

PLATE 8

This "hoop" electret motor built in 1967 by D. K. Walker has a stationary cylindrical electret. The rotor is made of four pairs of bent aluminum plates enclosing the electret. The motor requires no commutator. The motor has been operated for several years without any servicing.

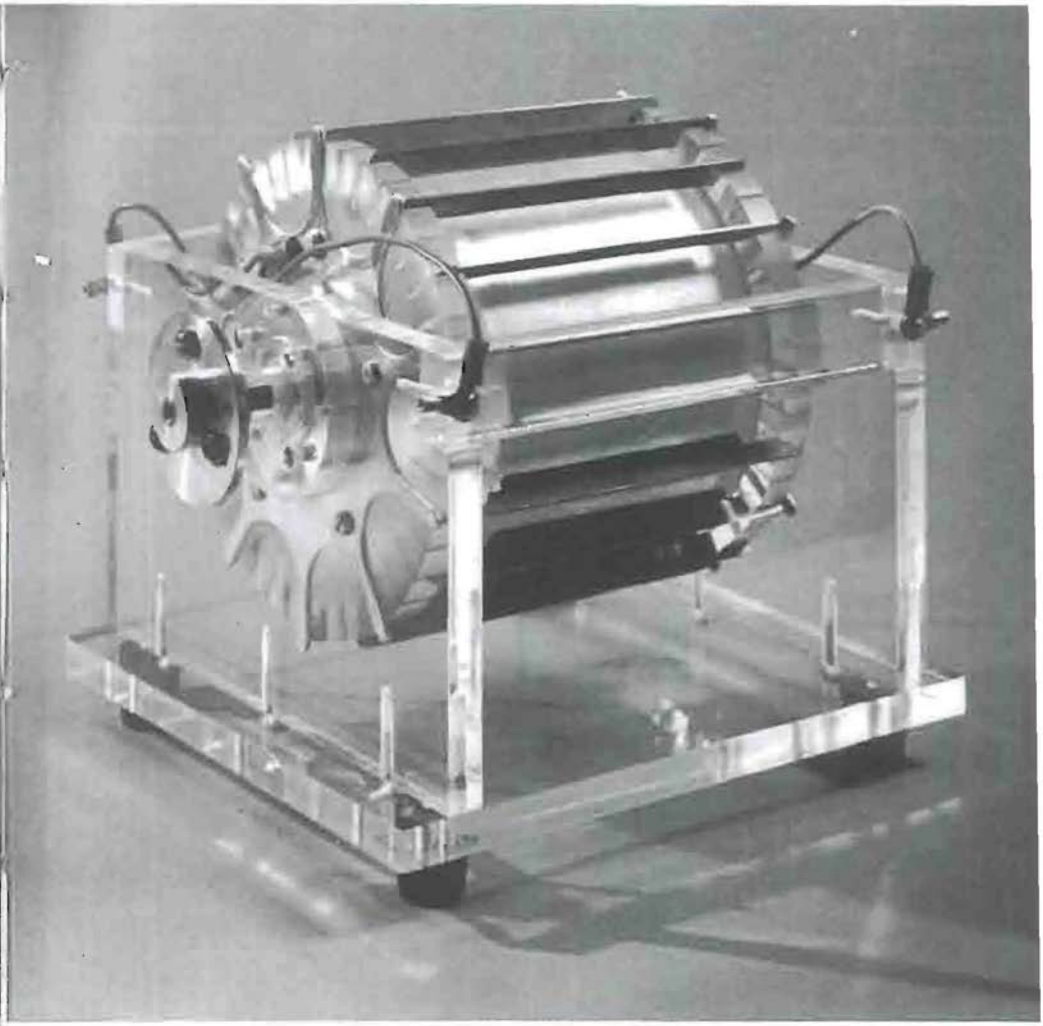

PLATE 9

Corona motors are probably the most promising electrostatic motors. This 0.1-hp modern version of the Poggendorff motor has a cylindrical rotor instead of a disk. The motor operates from a 6000-volt power supply as well as from an earth field antenna.

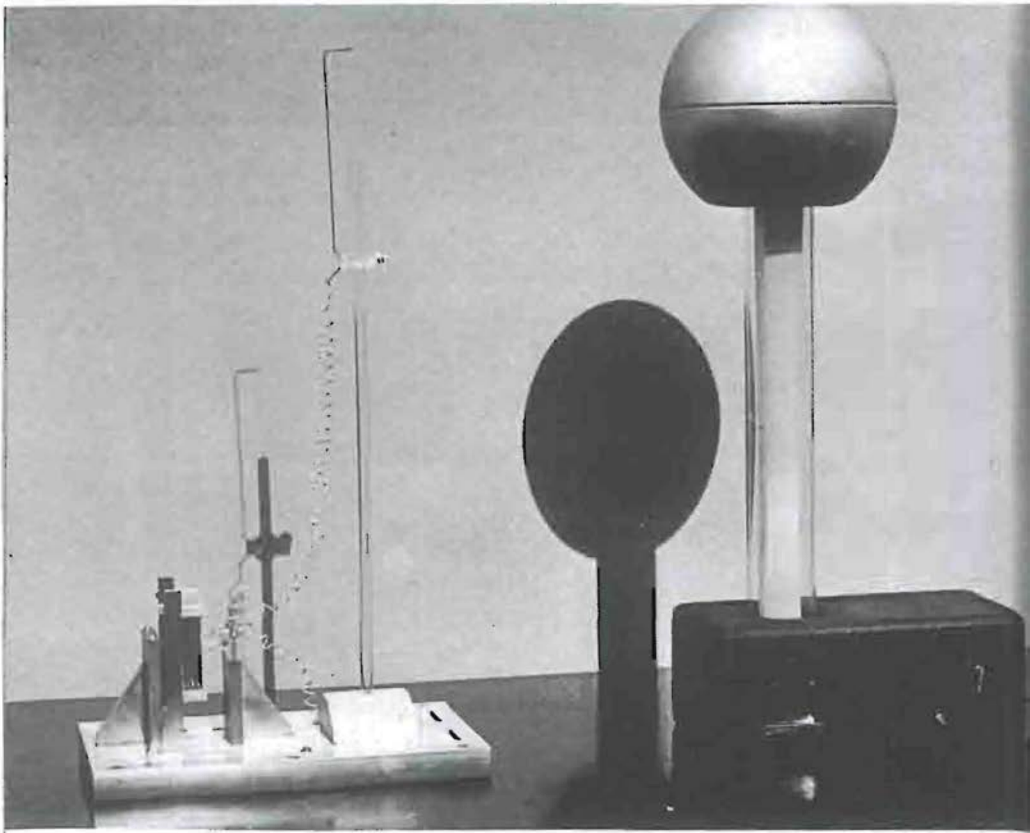

PLATE 10

The operation of electrostatic motors from antennas can be demonstrated with this lecture-room apparatus. The Van de Graaff generator produces electric charges in the air. The sharp-point antenna collects the charges from the air and delivers them to one terminal of an electrostatic motor whose other terminal is grounded.

PLATE 11

The author and D. K. Walker attempt to operate an electret motor from a 20-foot pole antenna in front of the Physics Building of the West Virginia University. The tall building screened the atmospheric field, and the motor did not run, although it operated very well from the same antenna in the nearby unobstructed parking lot.

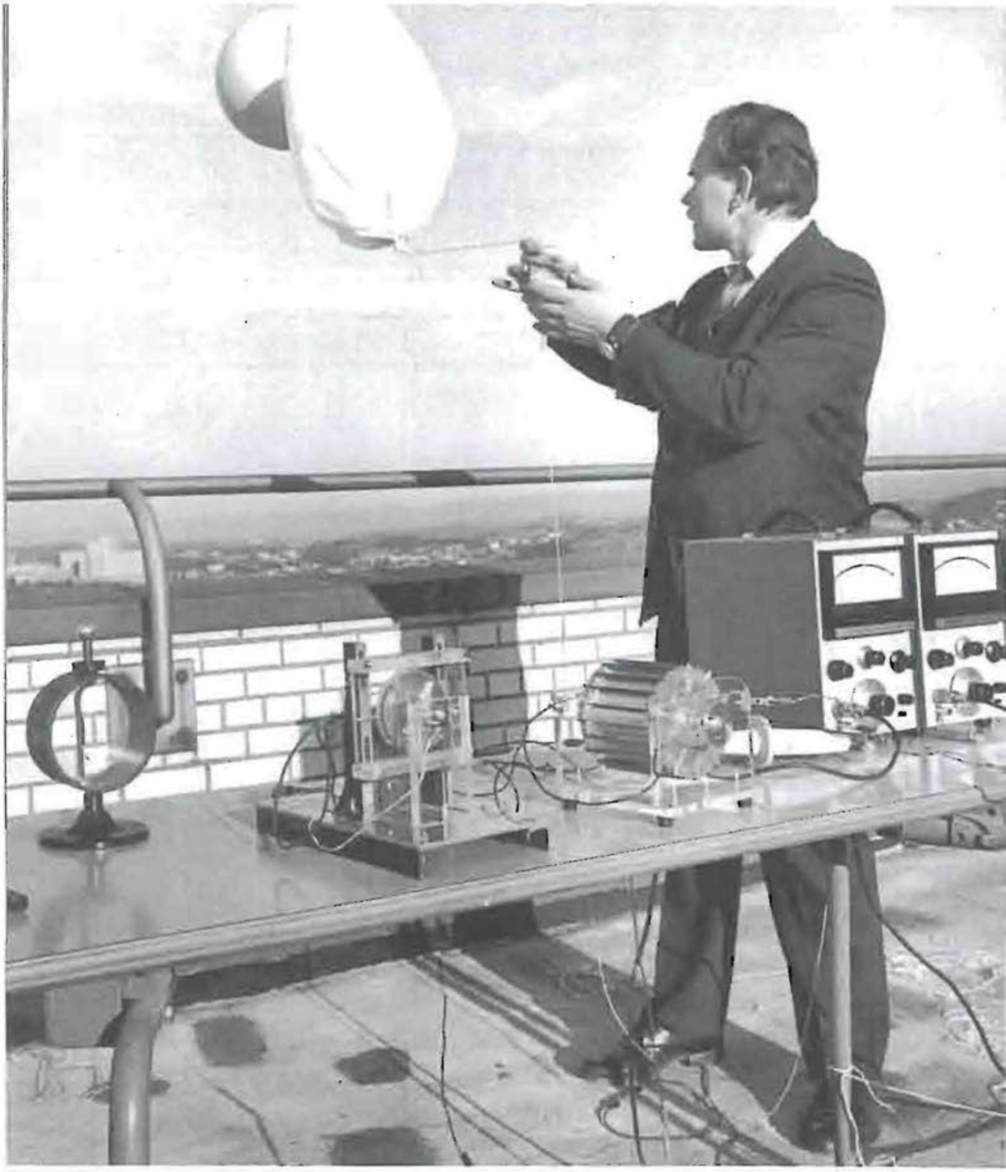

PLATE 12

The author operates electrostatic motors by means of an airborne antenna.

1

WHAT ARE ELECTROSTATIC MOTORS?

Conventional electric motors create mechanical motion as a result of magnetic forces acting upon electric currents. These motors are properly called *electromagnetic motors*. There is, however, another type of electric motor, in which the motion is created as a result of electric, or "electrostatic", forces acting between electric charges. Motors of this type are called *electrostatic motors*.

It is interesting to note that in nature the electrostatic forces are much stronger than the magnetic ones. There are many ways in which this can be demonstrated. For example, although a considerable effort may be needed to separate a magnet from an object attracted by it, a much greater effort is needed to break the magnet; this is because the magnet and the object are held together by magnetic forces, while the molecules of matter in the magnet (as well as in any other body) are held together by electrostatic forces.

Why, then, do we not use the electrostatic forces in our electric devices, and in motors in particular, at least on as wide a scale as we use the "inferior" magnetic forces? There are two main reasons for that. First, it is difficult to establish appreciable concentrations of electric charges without causing an electric breakdown in the medium surrounding or supporting the charges (although with modern insulating materials and techniques this difficulty becomes progressively less serious). Second, powerful electrostatic devices require voltages of many kilovolts for their operation, and until recently such voltages could not be produced conveniently and economically.

Motors of great power, however, are not the only ones needed. Equally important are low-power motors capable of performing various special tasks. In this respect electrostatic motors may compete successfully with their electromagnetic cousins even now.

Although electrostatic motors are not yet widely known or used, they already hold at least five very impressive records as compared with the electromagnetic motors:

1. The first electric motor ever invented was an electrostatic one. It was built about 100 years before the first electromagnetic motor was conceived.

2. The electric motor that operated without interruption longer than any other electric motor was an electrostatic one. This was a pendulum-type motor, known as the "electric perpetuum mobile", installed at the University of Insbruck, Austria, in 1823. Since then it operated continuously at least until 1909, powered by a Zamboni pile (an early high-voltage battery).
3. Electrostatic motors have been operated from voltages in excess of 10^5 volts, which is much higher than the voltages suitable for operating electromagnetic motors.
4. Electrostatic motors have been operated by using currents smaller than 10^{-9}amp, which is much less than the currents needed to operate electromagnetic motors.
5. The first electric motor that operated directly from the atmospheric electricity was an electrostatic motor. None of the presently available electromagnetic motors can operate directly from this source.

Even this short list reflecting some of the more obvious peculiarities of electrostatic motors shows quite clearly that electrostatic motors possess a number of unique properties. These properties undoubtedly will make electrostatic motors increasingly more important for the science, engineering, and technology of the future.

Many different types and designs of electrostatic motors are possible. It is customary to classify electrostatic motors in accordance with some prominent feature of their mode of operation or some prominent feature of their design. Thus, in reference to the techniques used for delivering electric charges to the active part of a motor one speaks of *contact motors*, *spark motors*, *corona motors*, *induction motors*, and *electret motors*. In reference to the medium in which the active part of a motor is located one speaks of *liquid-* or *gas-immersed motors*. In reference to the material and design of the active part of a motor one speaks of *dielectric motors* (the active part is made mainly of dielectric material) and *conducting-plate*, or *capacitor*, *motors* (the active part is made mainly of metal and resembles a variable capacitor). Finally, in reference to the rate of rotation of a motor relative to the period of the applied voltage (for ac operated motors) one speaks of *synchronous motors* and *asynchronous motors*.

This classification of electrostatic motors does not make it possible, however, to specify uniquely each individual motor. Also, two or more different operation modes are usually possible for most electrostatic motors (for example, certain motors can be operated at will as contact, spark, or corona motors). Therefore an assignment of a particular motor to one or another of the above types or categories is frequently more or less arbitrary. This applies, of course, also to the present book, where certain motors described in the chapters that follow could be equally well discussed under different chapter headings, and where the inclusion of certain motors in a particular chapter was occasionally dictated by the fact that such an inclusion resulted in a more coherent development of the subject matter.

2

ELECTRIC PENDULUM MOTORS; CONTACT MOTORS

If "electric motor" is understood to be a device converting electric energy into a continuous mechanical motion, then the first two electric motors were invented in the early 1740's by Andrew Gordon, a Scottish Benedictine monk and professor of philosophy at Erfurt, Germany.[1] Gordon's first motor was a device known as the "electric bells" (his second motor will be described in the next chapter). The device and its operation were as follows. A metallic clapper (pendulum) was suspended by a silk thread between two oppositely charged bells (Fig. 1). From an initial contact with one of the bells the clapper acquired a charge of the same polarity as that of the bell. Due to repulsion of like charges and attraction of opposite charges the clapper was then repelled by this bell and attracted by the second bell. As the clapper struck the second bell, it gave off its initial charge and acquired a charge of the same polarity as that of the second bell. Then the clapper was repelled by the latter and attracted by the first bell, which it struck again, and so on.

Numerous variations of Gordon's bells have been described by later authors, mostly as devices for lecture-room demonstrations of electrostatic forces. Such devices are widely used for this purpose even now.

An ingenious application of Gordon's bells was made by Benjamin Franklin in 1752. He connected the bells to an insulated lightning rod as a warning device "to give notice when the rod should be electrified".[2] (It appears that at that time neither Franklin nor any other scientist suspected how dangerous this "warning" device could be. The extreme danger of experiments with insulated lightning rods became clear a year later, when in 1753 the Russian physicist George Wilhelm Richmann was killed by lightning that entered his laboratory through such a rod, as he approached it in order to measure its electrification with a specially constructed electrometer.)

In a later modification of Gordon's invention one of the two bells was mounted on a Leyden jar (Fig. 2); the bells would then ring for as long as there was enough electric energy stored in the jar to move the clapper. (Franklin described the operation of an electric pendulum powered by a Leyden jar in 1747; see Ref. 2, p. 189.)

Sometimes Gordon's bells were made as a set

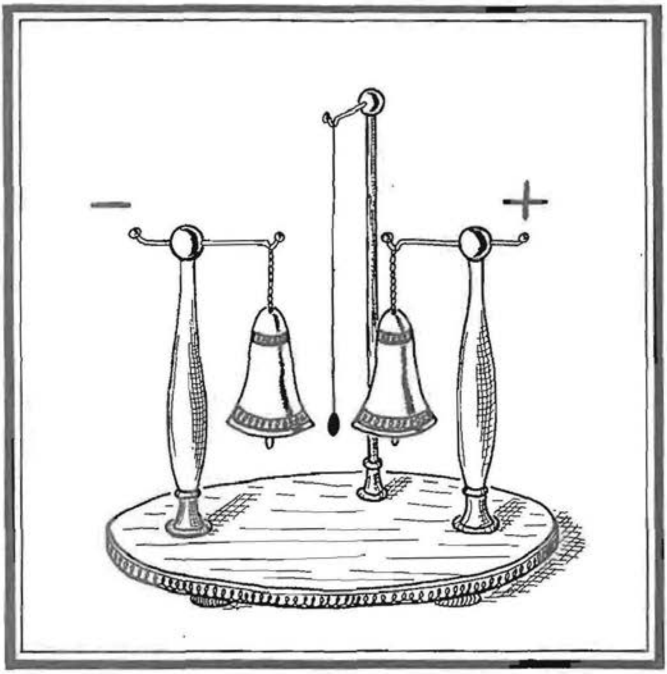

FIGURE 1

The so-called "electric bells" constituted the first device that converted electrical energy into a continuous mechanical motion. They were invented in about 1742 by Andrew Gordon, a professor of philosophy at Erfurt, Germany.

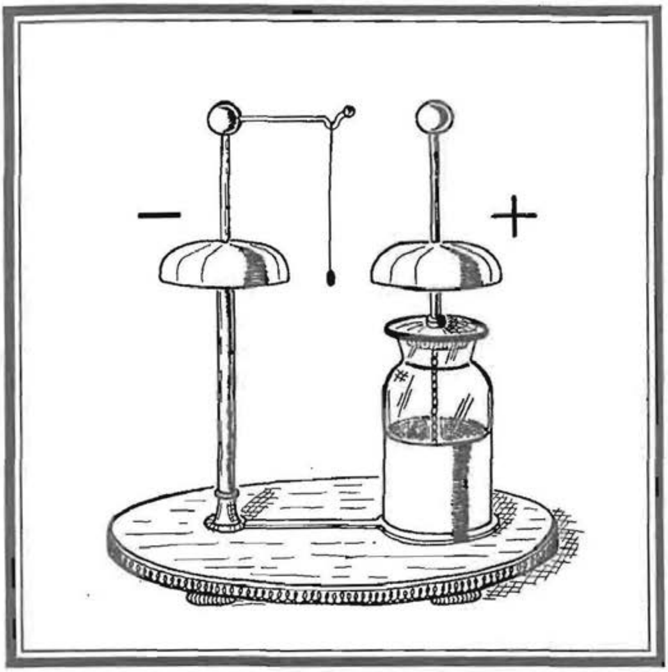

FIGURE 2

In a later modification of Gordon's invention one of the two bells was mounted on a Leyden jar. The bells would then ring for as long as there was enough electrical energy stored in the jar to move the clapper.

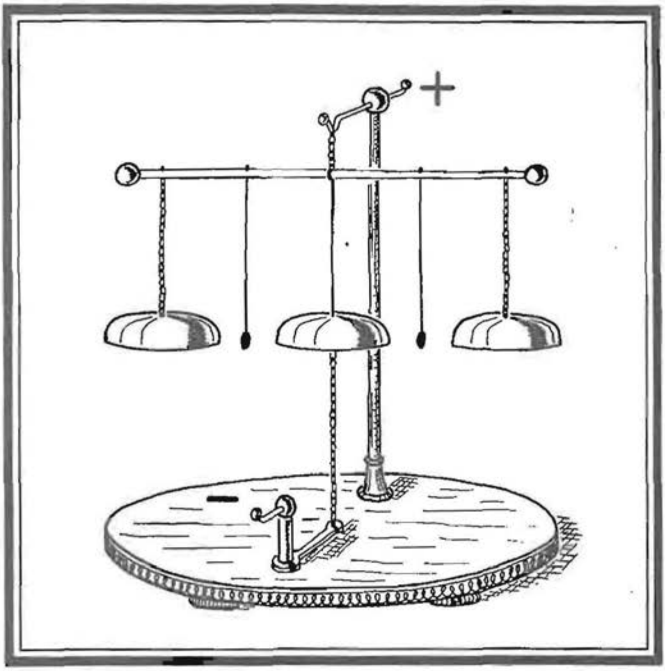

FIGURE 3

Sometimes Gordon's bells were made as a set of three bells and two clappers, all suspended from a horizontal bar, the central bell being insulated from the bar and grounded by means of a light chain.

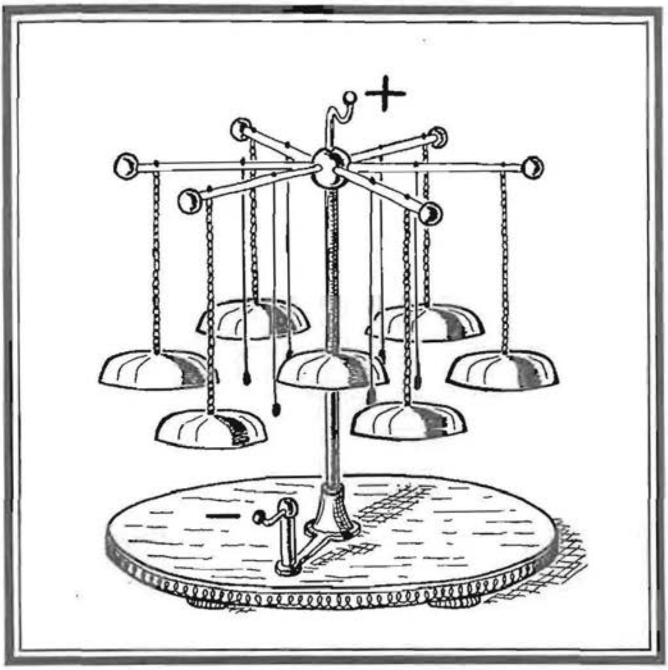

FIGURE 4

Another modification of Gordon's bells was a set of bell chimes arranged on a wooden base in a circular formation around the central bell. A separate clapper was then present for each of the outside bells.

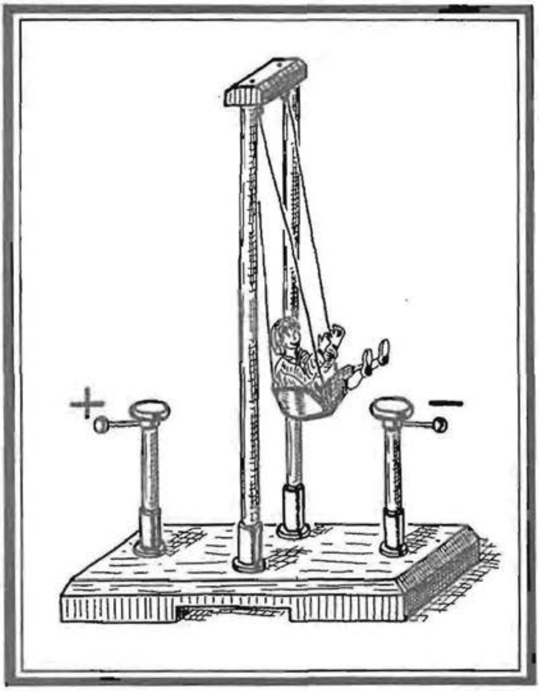

FIGURE 5

The electrical and mechanical principle of Gordon's invention could be used not only for ringing bells but for creating a mechanical motion in general. In this "electric swing" this principle was used to operate an animated toy.

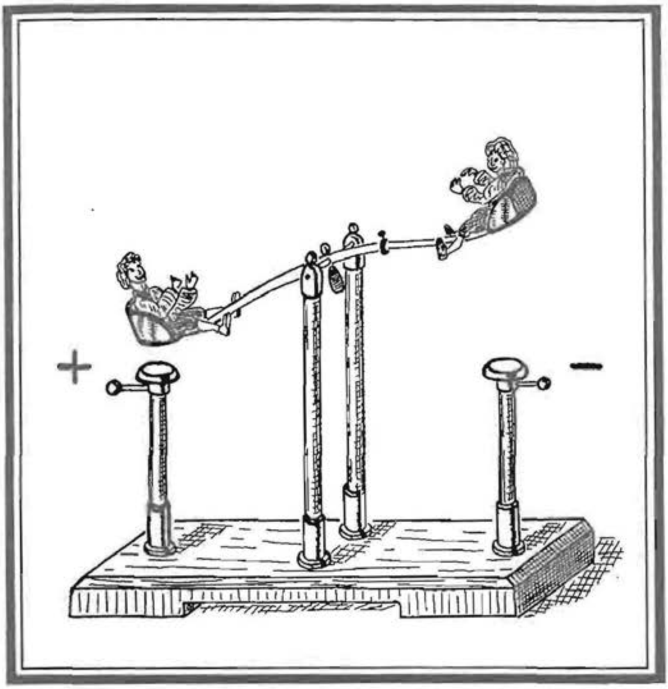

FIGURE 6

Various electrostatically operated toys were invented in the 18th and 19th centuries. This "electric seesaw" was basically a conducting bar oscillating about a horizontal axis on the same principle as the clapper of Gordon's bells.

of three bells and two clappers, all suspended from a horizontal bar, the central bell being insulated from the bar and grounded by means of a light chain (Fig. 3). Another modification of Gordon's bells was a set of bell chimes arranged in a circular formation around the central bell (Fig. 4); a separate clapper was then present for each of the outside bells, each clapper moving between one of the latter and the central bell (the central bell was usually grounded, the outside bells were connected to an electrostatic generator).

The electrical and mechanical principle of Gordon's invention could be used, of course, not only for ringing bells but also for a variety of other purposes. In particular, this principle was later used in two electrically operated toys: the "electric swing" and the "electric seesaw", which utilized, respectively, an insulated pendulum made as a swing (Fig. 5) and an insulated conducting swing bar capable of oscillating about a horizontal axis (Fig. 6).[3,4]

Except for Franklin's bells, all of the above devices were designed for operation from an electrostatic generator or from Leyden jars charged by such a generator. However, in 1806 a high-voltage chemical battery ("dry pile", later known as the "Zamboni pile") was invented by Georg Behrens, and in 1810 this pile was adapted by Giuseppe Zamboni to operate primitive electrostatic motors.[5] Inasmuch as a Zamboni pile could remain active for many years, the little motors that operated from it were known as the "electric perpetuum mobile". An example of such a perpetuum mobile is shown in Fig. 7 (see Chapter 4 for another design). The apparatus consisted of a light rigid insulated pendulum, pivoted just above the center of gravity, with a light conducting ring at the top. The ring was located between the two knobs of a Zamboni pile. When the ring contacted one of the knobs, it acquired a charge from the knob and was repelled from this knob and attracted to the second knob, and so on, just like the clapper in Gordon's bells. One such perpetuum mobile is reported to have operated without interruption for at least 86 years.[6]

The most sophisticated device derivable from Gordon's electric bells was probably the reciprocating electrostatic motor (Fig. 8 and Plate 1) built in 1880 by Howard B. Dailey and Elijah M. Dailey.[7] The motor, which is now at the Museum of History and Technology of the Smithsonian Institution, was described by one of its builders as follows:

"This machine operates by the direct action of static electric attractions and repulsions. It is constructed entirely of fine wood, glass and hard rubber, there being no magnetic materials used. The flywheel is of laminated, soft wood and runs in journal bearings of very small diameter. The moving balls, mounted on the walking beam of vulcanite, are made of wood, hollowed out so that the walls are about 2 millimeters thick.

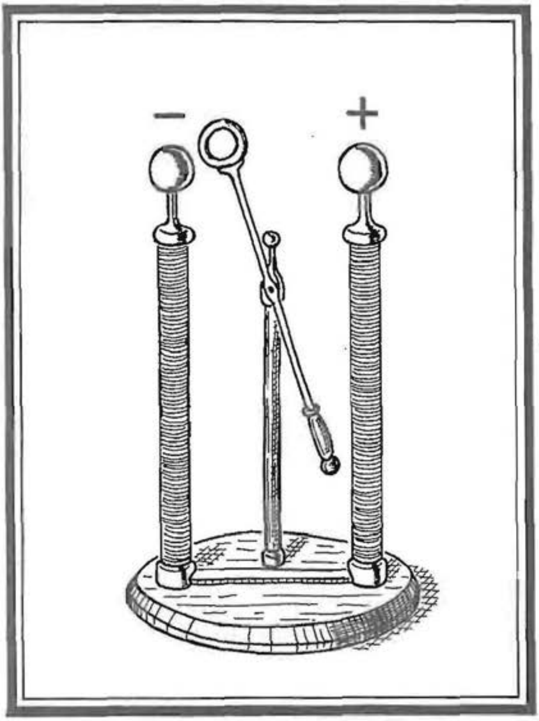

FIGURE 7

This electric pendulum operated from a Zamboni pile, an early high-voltage battery. Since the pile remained active for years, the pendulum was known as an "electric perpetuum mobile".

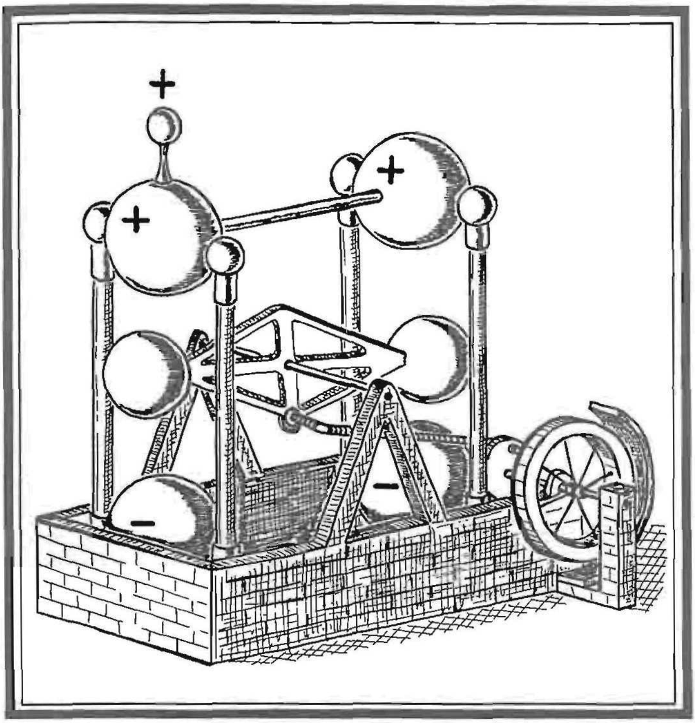

FIGURE 8

The most sophisticated device derivable from Gordon's bells was probably this reciprocating electrostatic motor built in 1880 by H. B. Dailey and E. M. Dailey.

They are covered with aluminum foil for static conductivity. The stationary balls are of solid wood.

"To operate the engine the stationary balls are charged with electricity from a static electric generator, such as a Holtz machine, the upper balls being connected through the brass ball to one pole of the machine while the lower stationary balls are connected through the binding post on the bed frame to the opposite pole of the machine. Under proper conditions, when charged, the engine will make about 375 revolutions per minute.

"The walnut base upon which the engine is mounted is 14" long, 4" wide and 1¾" thick. The movable balls are about 1½" in diameter; the upper stationary balls are 1¾" in diameter; and the lower stationary balls, 1½". The four glass rods, mounted vertically, are about 6" high and spaced 6" apart along the bed. The diameter of the flywheel is 5¾". It is gilded and has small wire spokes. The connecting rod is 7" in length."*

The electric principle of Gordon's bells could be used also for producing a continuous unidirectional motion. A fascinating device of this type was the "electric racing ball", or the "electric planetarium", an excellent description of

---

*The author is grateful to Mr. Elliot N. Sivowitch, Smithsonian Institution Museum Specialist, for kindly providing this description and the photograph of Dailey's motor.

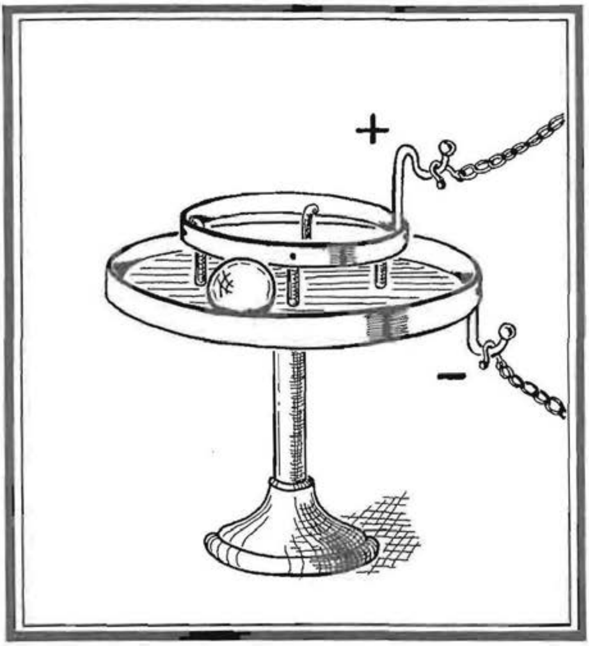

FIGURE 9

The electric principle of Gordon's bells could be used also for producing a continuous unidirectional motion. This "electric racing ball" was propelled along a conducting hoop by the same mechanism that moved the clapper in Gordon's bells.

which has been provided by M. Guyot.[8] The apparatus consisted of an insulated horizontal conducting hoop positioned above a conducting disk having a vertical rim concentric with the hoop (Fig. 9). The arrangement constituted a track for a light sphere of glass placed on the disk between the hoop and the rim. When the hoop and the disk were connected to an electrostatic generator, the sphere ran along this track due to attraction and repulsion exerted by the hoop and the disk upon the points of the sphere that acquired charges from contact with the disk and the hoop (the rolling of the sphere usually had to be initiated with a light push by hand, but once the sphere had started to run, it continued running for as long as the electrostatic generator was in operation).

Since the moving elements in the above described motors were charged by contact, the motors may be classified as "contact motors". This method of charging, however, is neither the only possible nor the most expedient one. Therefore contact motors will probably always be subordinate to most of the motors described in the following chapters. In this connection it may be useful to note that, upon a closer examination of the operation of Gordon's bells and other similar devices, one recognizes that the charging of the moving elements in these devices usually occurs by means of a spark that jumps from a stationary electrode (bell) to a moving element (clapper) as soon as the latter comes close enough to the former. Thus the actual physical contact between the moving and stationary components in these devices is not at all necessary for their operation. In fact, such a contact is harmful insofar as it results in energy losses from impact and friction.

3

ELECTRIC WIND MOTORS

As already mentioned in the preceding chapter, Andrew Gordon invented two electric motors. His second motor was the "electric fly",[1,2] also known as the "electric whirl", "electric pinwheel", or "electric reaction wheel" (Fig. 10). The electric fly consisted of one or more light metal arms with sharp-point ends bent at right angles to each arm and in the same circumferential direction. The fly was pivoted at its center on an insulated needle. When the needle was connected to an electrostatic generator, a corona discharge* took place from the sharp points of the fly. The air near these points became charged with charges of the same polarity as that of the fly and was then repelled from the points due to repulsion of like charges (the resulting motion of the air is known as the "electric wind"). Similarly, the points themselves were repelled from the charges in the air, and the fly rotated therefore in the opposite sense to that in which the points were directed.

---

*Corona discharge is a spontaneous electric conduction in a gas (air) originating from sharp conducting bodies whose electrostatic potential relative to the ground is 3000 volts or higher.

Also the electric fly was used for ringing bells or chimes. This was accomplished by suspending from the fly a clapper, which, as the fly rotated, struck in turn several bells positioned in a circular formation underneath the fly (Fig. 11).[3]

In 1760, Hamilton, professor of philosophy at Dublin, suggested to use a similar device as an electrometer.[4] In this electrometer small weights were suspended from the fly. As the fly turned, the weights were deflected from the vertical direction by centrifugal forces. This deflection was a measure of the fly's speed and, hence, of the strength of the source to which the fly was connected. A more sophisticated electrometer utilizing the electric fly was described by Jakob Langenbucher,[5] a silversmith at Augsburg, Germany, who spent a large part of his time and fortune on improving electrostatic generators and studying electrostatic phenomena. In this electrometer the fly was mounted on a thin vertical cylinder. A fine string was fastened to the cylinder. The string passed over a small pulley and had a light pan attached to its free end. A small weight was placed on the pan. As the fly turned, the string

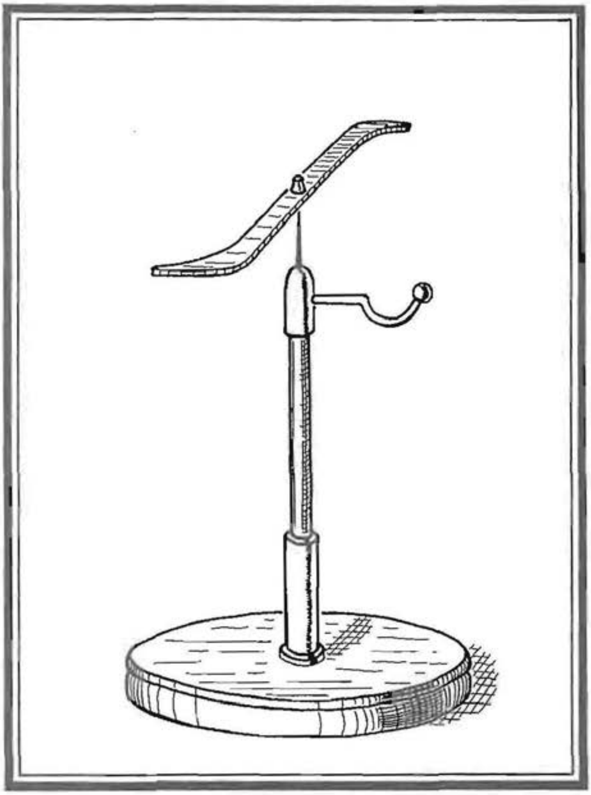

FIGURE 10

Andrew Gordon invented two electric motors. His second motor was the so-called "electric fly".

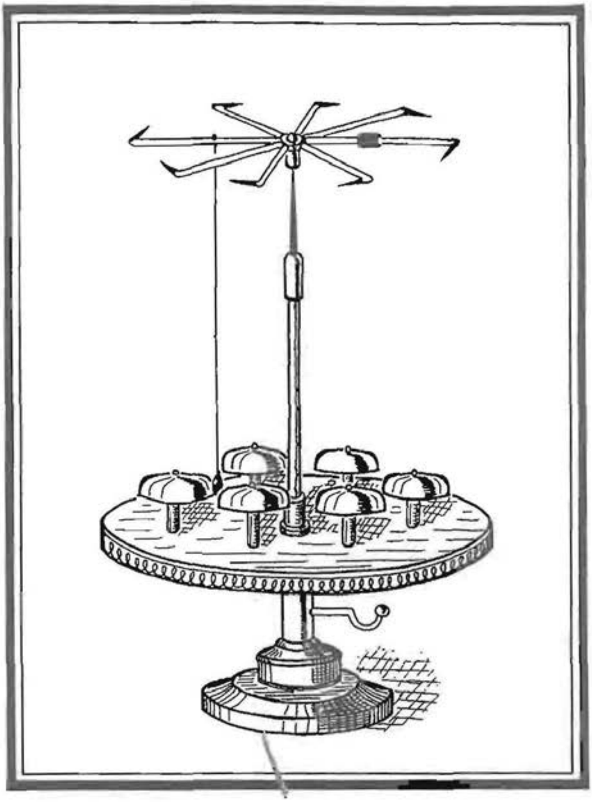

FIGURE 11

Also the electric fly was used for ringing bells with the aid of a clapper suspended from it.

wound itself on the cylinder lifting the pan and the weight. The maximum weight that could be lifted by this electrometer was a measure of the strength of the source from which the fly was operated.

The principle of the electric fly was later used to operate an orrery depicting the orbital motions of the Sun, the Moon, and the Earth (Fig. 12).[6] In such an orrery, also known as the "electrical tellurium", the longer bent arm carried a large sphere at one end, while at the other end it carried a similar but smaller bent arm, each end of which also carried a small sphere. The three spheres represented the Sun, the Moon, and the Earth. The arms were pivoted on sharp points, and each arm had a perpendicular sharp point in the horizontal plane. When the instrument was connected to an electrostatic generator, the two systems rotated about their points of support, the smaller system, being lighter, rotated more rapidly than the larger one. The relative masses of the spheres were adjusted to make the Earth-Moon system rotate twelve times for every single rotation of the Sun.

An interesting variation of the electric fly was constructed in 1761 by Ebenezer Kinnersley, a Philadelphia school teacher and close friend of Benjamin Franklin. Kinnersley called his device the "electrical horse-race".[7] This was a cross formed by two pieces of wood of equal length (probably about 18 inches long) supported horizontally on a central pin. A light figure of horse

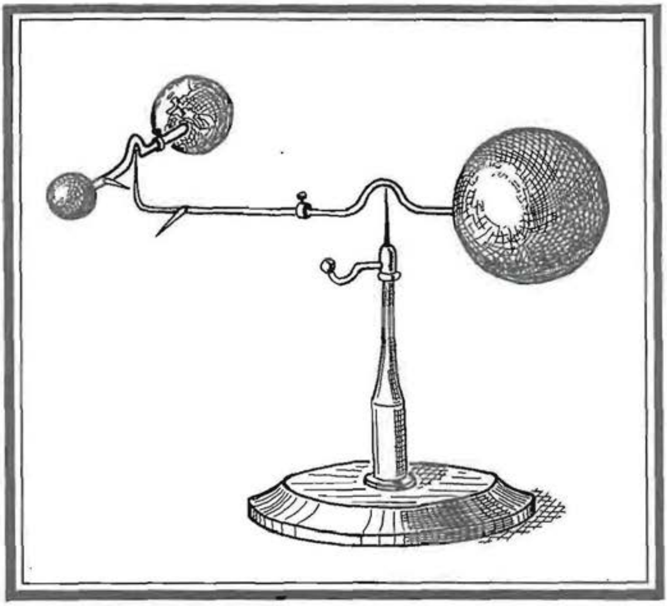

FIGURE 12

The principle of the electric fly was later used to operate an orrery depicting the orbital motions of the Sun, the Moon, and the Earth. The masses of the spheres were adjusted to make the Earth-Moon system rotate twelve times for every single rotation of the Sun.

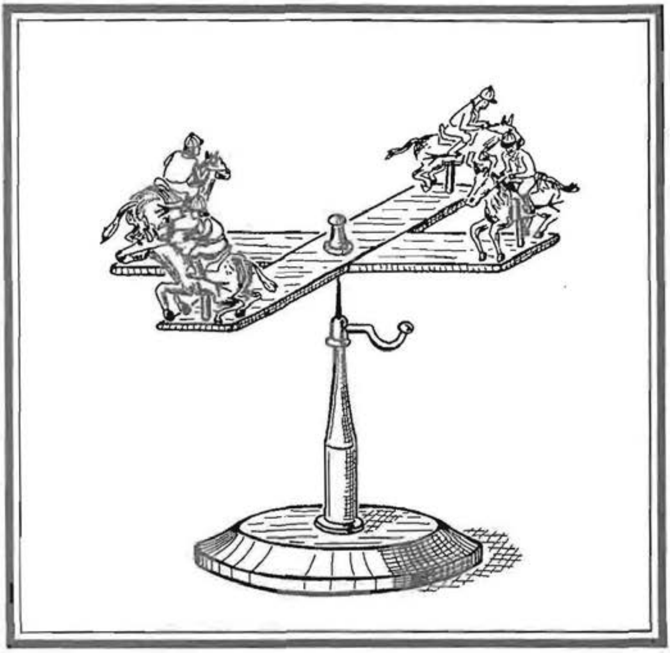

FIGURE 13

An interesting variation of the electric fly was constructed in 1761 by Ebenezer Kinnersley, a friend of Benjamin Franklin. Kinnersley called his device the "electrical horse-race". The electrical horse-race was a popular toy in the latter part of the 18th century.

with his rider was placed upon each extremity of the cross. The motion was produced by corona discharge from the spurs of the riders (Fig. 13). The electrical horse-race was a popular toy in the latter part of the 18th century. Interesting descriptions of this toy have been provided by Langenbucher (Ref. 5, p. 206 and Plate 8), and by Guyot.[8]

To show more convincingly that the electric fly converted electrical energy into mechanical energy, electric flies were placed on horizontal axes and were arranged to lift small weights (Fig. 14) or to climb inclined rails (Fig. 15).[9]

Operation of the electric fly in liquids was investigated by Aimé.[10] A historical account of electric fly studies was presented by Tomlinson.[11] The mechanism of the fly was discussed at some length by Mascart.[12] A quantitative study of the forces acting upon the electric fly was performed by Kämpfer.[13]

A more efficient modification of the electric fly was proposed in 1887 by Bichat.[14] Bichat's electric "tourniquet" consisted of a light vertical frame capable of turning about a vertical axis and supporting two thin vertical wires producing a corona discharge along their entire length. The vertical sides of the frame acted as "spoilers" preventing a corona discharge from the "back side" of the wires. A simple motor based on Bichat's device is shown in Fig. 16.

In recent years the principle of the electric fly (reaction force experienced by a sharp point as a

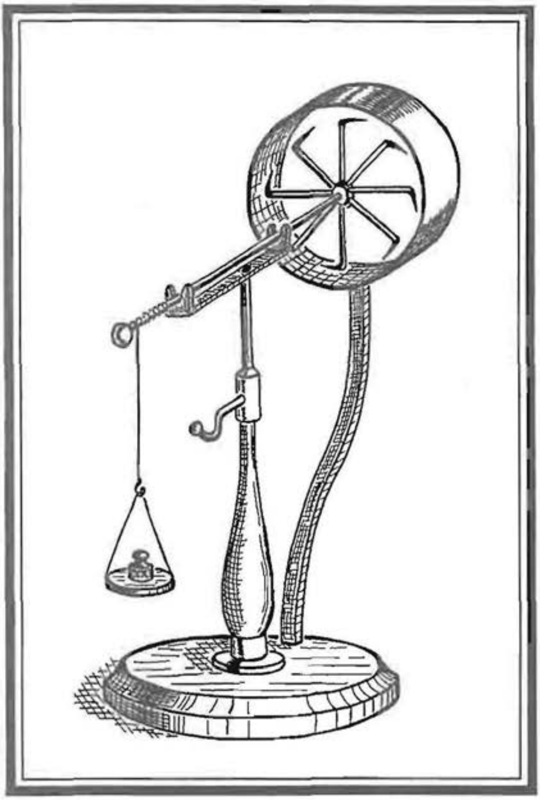

FIGURE 14

Electric fly converted electrical energy into mechanical energy and could lift small weights.

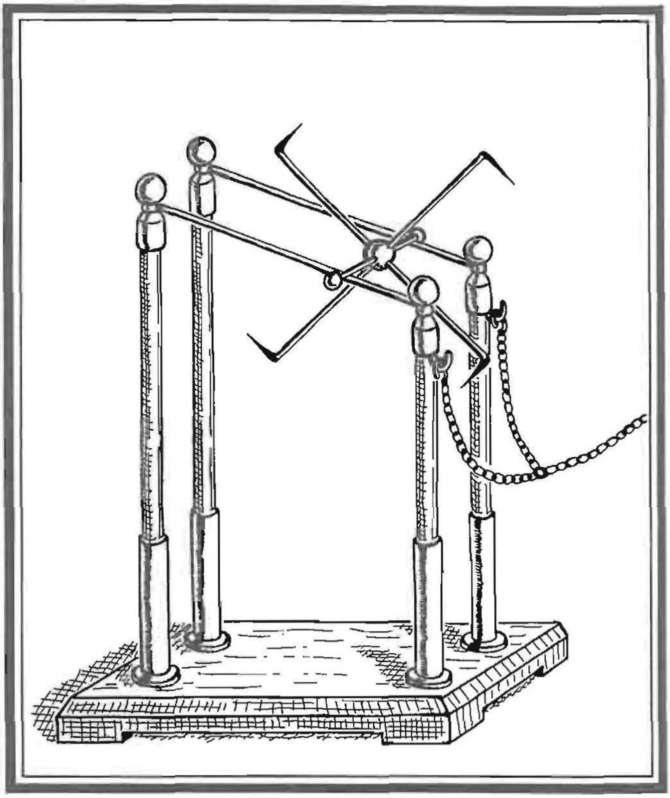

FIGURE 15

Electric fly developed enough mechanical energy for climbing inclined rails.

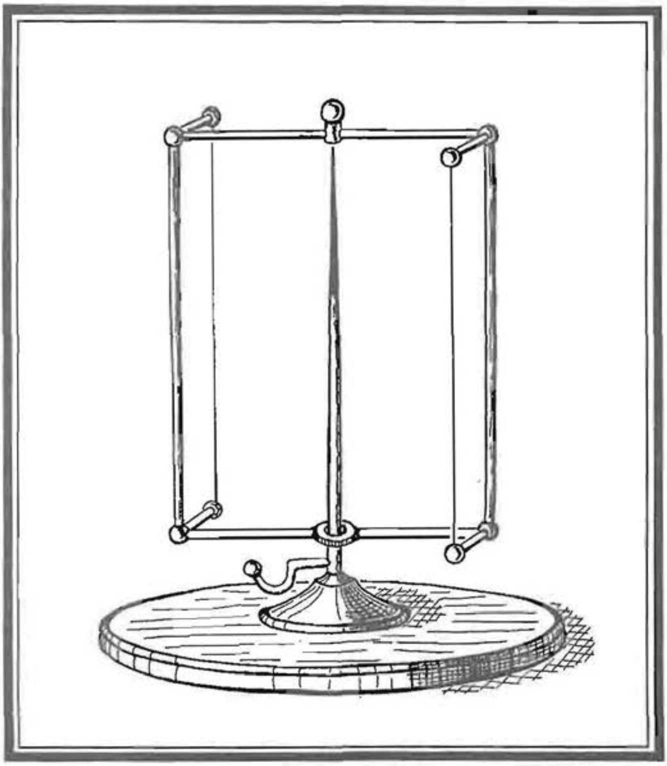

FIGURE 16

A more efficient modification of the electric fly was proposed in 1887 by Bichat, who called his device the "electric tourniquet".

result of a corona discharge from it) has been suggested for a flying machine ("corona-kraft levitation").[15] The lift realizable from such a machine does not, however, appear to be of practical significance.[16]

Closely related to the electric fly were the "electric wind wheels" and the "electric wind turbines". Like the electric fly, they were invented in the 1740's and utilized a corona discharge from sharp points for their operation. Benjamin Franklin studied these devices in 1747 (he first learned of them from his friend Philip Syng). According to Franklin (Ref. 7, p. 184) they were "light windmill-wheels made of stiff paper vanes; also. . .little wheels, of the same matter, but formed like water-wheels". Their probable appearance was as shown in Figs. 17 and 18. Later versions of these devices have been described by Guyot (Ref. 8, pp. 274, 275 and Plate 27), by Langenbucher (Ref. 5, pp. 75, 76 and Plate 3), by Gale,[17] and by Neuburger.[18]

A delightful electric toy using the electric wind for its propulsion was made by W. R. King, an associate of James Wimshurst (the designer of the electrostatic machine carrying his name). This toy, which may be called an "electrical rabbit hunt", now at the Science Museum in London, is shown in a simplified form in Fig. 19. It consists of a small electric wind turbine mounted on a vertical shaft carrying five light metal arms on its upper end; the arms support

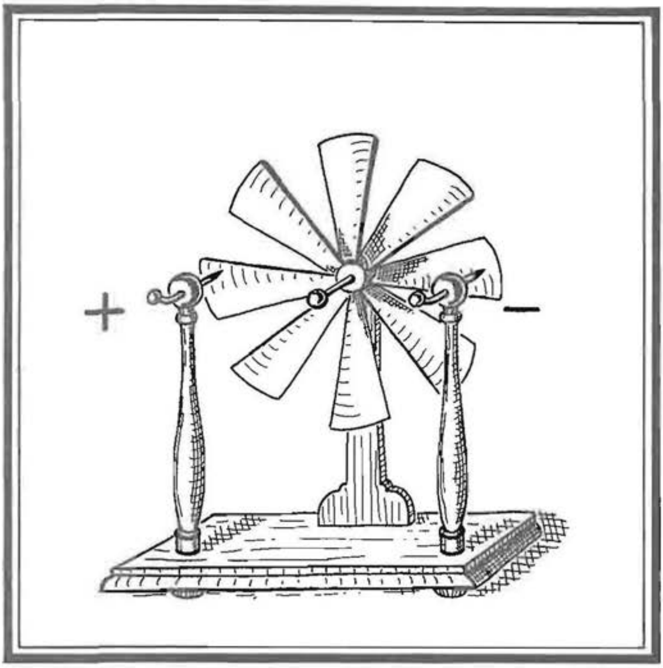

FIGURE 17

Closely related to Gordon's electric fly was the "electric wind wheel". Like the electric fly, it was invented in the 1740's and utilized a corona discharge from two sharp points for its operation.

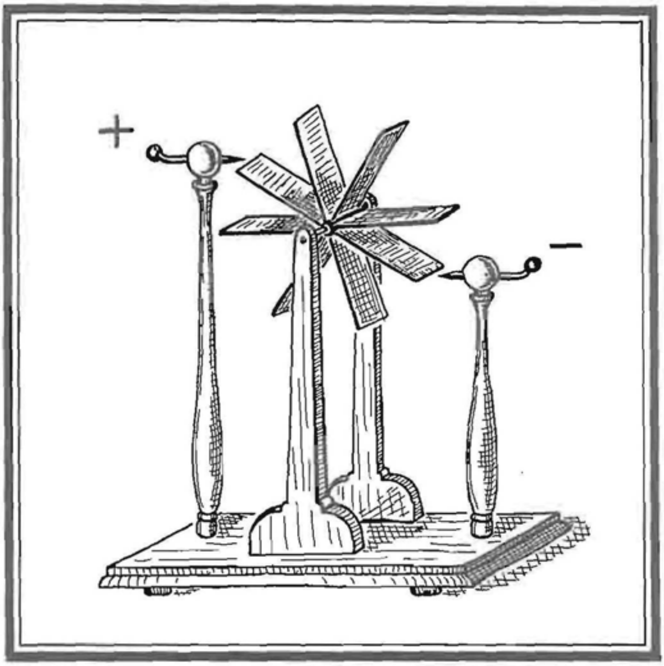

FIGURE 18

Benjamin Franklin studied this "electric wind turbine" in 1747. He concluded that its action depended not as much on the electric wind as on the forces between the charges present on its moving and stationary parts.

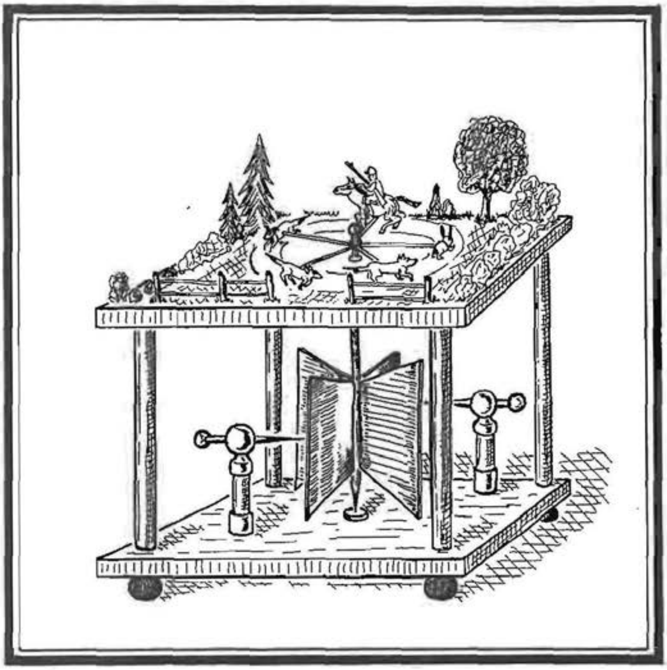

FIGURE 19

figurines of a rabbit, three dogs, and a horseman, who chase each other in a beautiful little garden, as the arms turn powered by the turbine below.

In studying the electric wind motors, Benjamin Franklin concluded that their action depended not as much on the electric wind as such, but on the repulsion and attraction of electric charges present on the moving and stationary parts of the motors (Ref. 7, p. 184). It is very probable that this conclusion led him to the invention of his big electric motors, the famous "electrical wheels", which are described in the next chapter.

FRANKLIN'S SPARK MOTORS AND THEIR DESCENDANTS

If one defines the "electric motor" as a machine capable of converting substantial amounts of electrical energy into mechanical energy, then it was Benjamin Franklin who invented the electric motor, for he was the first person to design and to construct a machine capable of accomplishing such a conversion.

Franklin built two electric motors, which he called "electrical wheels". He described them in a letter to Peter Collinson, Fellow of the Royal Society of London, written in Philadelphia in 1748.[1]

His first motor was a big machine, about 40 inches in diameter. The main part of this motor was a wooden disk mounted horizontally on a vertical wooden axle and carrying 30 glass spokes with brass thimbles on their ends (Fig. 20 and Plate 2). The axle turned on a sharp point of

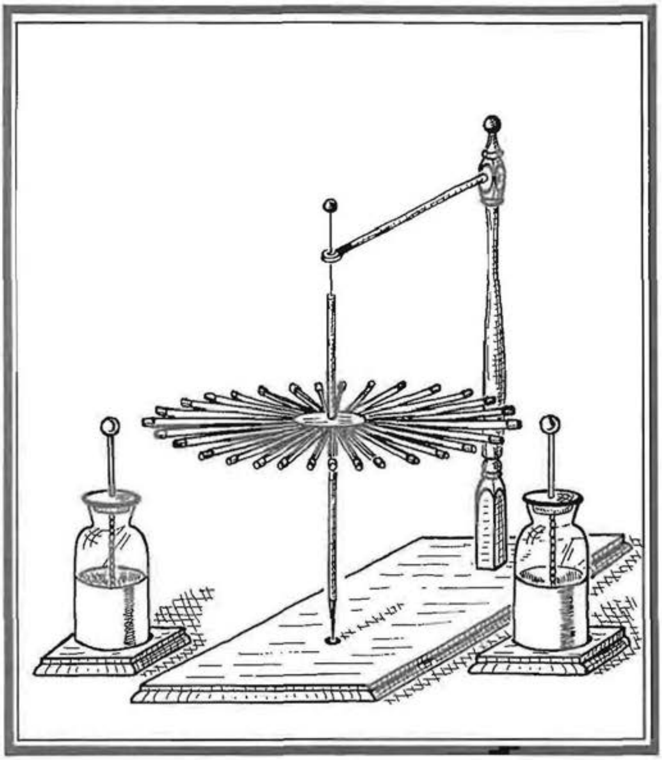

FIGURE 20

Franklin's first "electrical wheel" was the earliest device converting substantial amounts of electrical energy into mechanical energy.

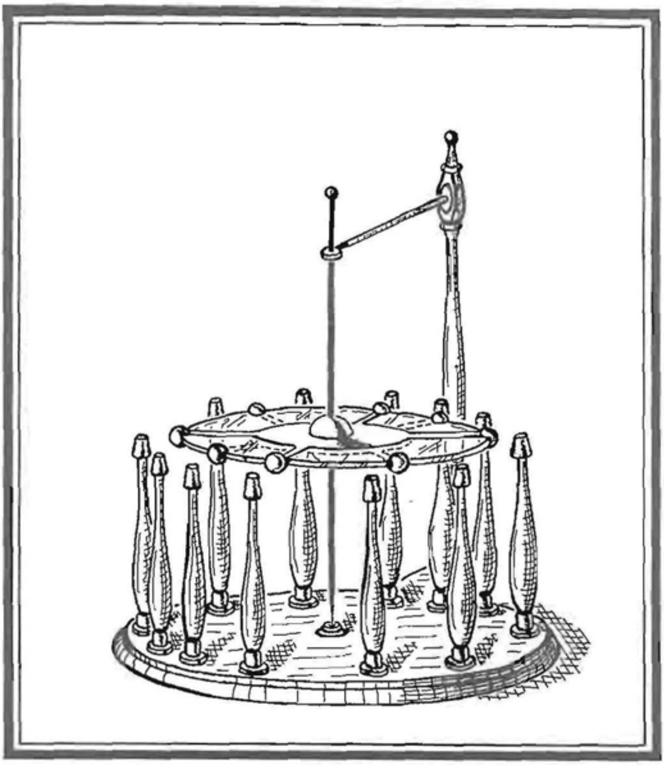

FIGURE 21

Franklin's second "electrical wheel" was more efficient than the first. It was powered by the electric charge stored in its capacitor-rotor.

iron fixed in its lower end and was kept in the vertical position by a strong wire mounted in its upper end and passing through a small hole in a thin stationary brass plate. Two oppositely charged Leyden jars (bottles) were placed in close proximity to the thimbles on the spokes, so that when the wheel turned, the thimbles barely missed the knobs of the jars.

As the thimbles moved past the Leyden jars, a spark jumped between a jar knob and the passing thimble, charging the latter with a charge of the same polarity as that of the knob. Therefore each knob attracted the oncoming thimbles ("opposite charges attract") and repelled the departing thimbles ("like charges repel"), causing the motor to turn. The motor, being perfectly symmetric, could turn in either direction, and usually required a starting push by hand to initiate the charging of the thimbles.

Here is how Franklin himself described the operation of his motor:[1]

"If now the wire of a bottle, electrified in the common way, be brought near the circumference of this wheel, it will attract the nearest thimble, and so put the wheel in motion; that thimble, in passing by, receives a spark, and thereby being electrified, is repelled, and so driven forwards; while a second being attracted, approaches the wire, receives a spark, and is driven after the first, and so on till the wheel has gone once round, when the thimbles before electrified approaching the wire, instead of being attracted as they were at first, are repelled, and the motion presently ceases. But if another bottle, which had been charged through the coating (e.i. charged oppositely to the first, O. J.), be placed near the same wheel, its wire will attract the thimble repelled by the first, and thereby double the force that carries the wheel round; and, not only taking out the fire (electric charge, O. J.) that had been communicated to the thimbles by the first bottle, but even robbing them of their natural quantity, instead of being repelled when they come again towards the first bottle, they are more strongly attracted, so that the wheel mends its pace, till it goes with a great rapidity, twelve or fifteen rounds in a minute, and with such strength, as that the weight of one hundred Spanish dollars, with which we once loaded it, did not seem in the least to retard its motion".

Franklin was not quite pleased with this motor, however, because it required "a foreign force, to wit, that of the bottles" for its operation. He constructed therefore a second, "self-moving", motor, which itself contained the electrical energy to be converted into the mechanical motion.

The second motor was made as follows (Fig. 21 and Plate 3). A disk of window glass, 17 inches in diameter, was gilded on each side, except for narrow areas next to the edge. Several lead spheres (bullets) were fixed to the edge of the disk and were connected in alternation to the two gold layers. The disk was mounted on a vertical axle consisting of two pieces of strong wire, each about 9 inches long; the upper wire being in contact with the top layer of gold, the lower wire being in contact with the bottom layer. The lower wire terminated in a sharp point resting on a piece of brass cemented within a glass salt-cellar. The upper wire passed through a hole in a thin brass plate cemented on a long strong piece of glass. This wire carried a small ball on its upper end for preventing a corona discharge from it. Several glass pillars with thimbles on their tops were positioned in a circle around the disk, so that the spheres on the edge of the disk barely missed the thimbles when the disk was in motion. The motor was powered by electricity stored in the disk itself, which, due to the two layers of gold, constituted a capacitor capable of storing an appreciable quantity of charge (to charge the rotor, the two layers of gold were temporarily connected to an electrostatic friction generator).

The motor operated on the same principle as Franklin's first motor, except that now the thimbles were stationary and received positive or negative charges from the passing spheres, rather than the other way around. As in the first motor, the rotation persisted as long as there was enough charge stored in the capacitor (rotor) to produce sparks between the spheres and the thimbles.

Franklin reported that his second motor

(which was more powerful than the first one) could make 50 turns in a minute and could run for up to 30 minutes on a single charging of the rotor.[1] Experiments with replicas of Franklin's motors performed by the author indicate that the original motors developed a power of the order of 0.1 watt,[2,3] which was a very impressive achievement for that very early period in the history of electric science.

Several authors have described simplified versions of Franklin's motors.[4,5] Miniature Franklin-type motors have been constructed and described by A. D. Moore[6] (Fig. 22). One such motor consists of a Plexiglas disk about 4 inches in diameter with small conducting balls embedded in the rim. The disk turns on a horizontal axis supported by a base behind the disk. The motor runs when placed between two conductors connected to an electrostatic generator. To make the motor self-starting and one-way running, the conductors may be provided with short auxiliary rods tangential to the disk; since the rods dispatch sparks predominantly in the direction of their free ends, the disk also turns in this direction. Another little motor of the same type designed by Moore is shown in Fig. 23.

An obvious improvement of Franklin's motors would be to use a cylindrical rotor with electrodes in the shape of long strips. Such electrodes would accept more charge than thimbles or spheres, and the power of the motor would be increased considerably. Motors of this type

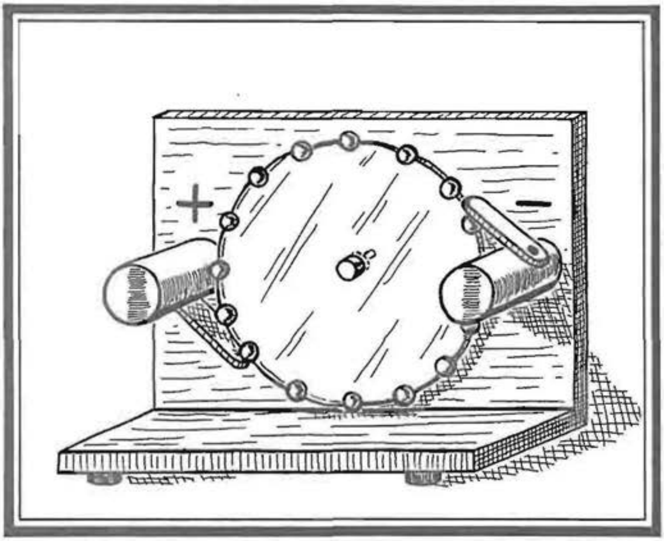

FIGURE 22

Several authors have described simplified versions of Franklin's motors. One such motor consists of a Plexiglas disk about 4 inches in diameter with small conducting balls embedded in the rim. The disk turns on a horizontal axis supported by a base behind the disk.

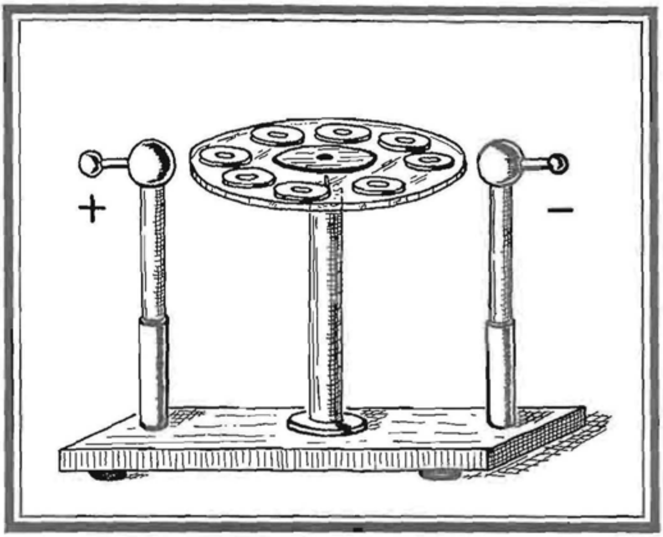

FIGURE 23

This inexpensive miniature Franklin-type motor of recent design can be used for lecture-room demonstrations of electrostatic forces. The rotor disk can be made from cardboard, wood, or plastic. For the rotor electrodes one can use thumbtacks or small aluminum foil disks.

have indeed been constructed. Here is a description of a "bell jar" motor taken from a book published in 1847 (Fig. 24):

"On a pivot, *a*, suspend a bell jar having four pieces of tinfoil pasted on its sides, *b*, *c*, *d*; connect the jar, by means of the insulated wire, *y*, with the prime conductor (high-voltage terminal of an electrostatic friction generator, O. J.) so that the pieces of tinfoil may receive sparks. On the opposite side arrange a conductor, *x*, in connection with the ground by a chain. On putting the machine into activity, the jar will commence rotating on its pivot."[7]

Small motors closely related to both Franklin's first motor and to pendulum motors were used in the rotary-type "perpetuum mobile" (see Chapter 2) operated from a Zamboni pile.[8] The main part of these motors (Fig. 25) was a light insulated arm pivoted on a sharp point and carrying a piece of tinsel on each end. The tinsels could just touch the knobs of the pile when the arm was moving on its pivot. The device functioned in the same manner as Franklin's first motor, the two tinsels corresponding to the thimbles of the latter.

An analogous design has recently been described as a "millifleapower motor" operating from a nuclear battery.[9] In this motor a light aluminum vane with pointed ends (Fig. 26) bent so as to form an inverted V is mounted at its midpoint on the tip of a sharp needle protruding from the positive terminal of the battery. As the

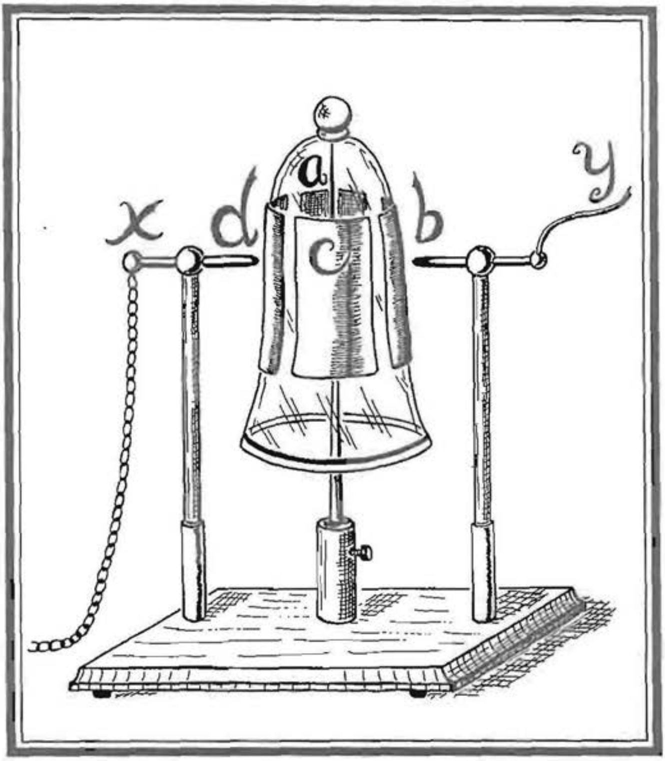

FIGURE 24

vane turns, its ends come close to two spheres connected with the ground through a high resistance and become attracted by them. A discharge from the ends of the vane charges the two spheres, and the spheres then repel the ends of the vane. During the time it takes the vane to complete one half of its revolution, the charges of the spheres leak off to the ground, so that the spheres can again attract the ends of the vane, accept new charges from them, and then again repel them. The motor is expected to run for many years.

An interesting motor derivable from Franklin's first motor and from pendulum motors was suggested for operation from an electrophorus.[10] The main part of this motor (Fig. 27) was a light conducting ring supported in a vertical plane on an insulated needle. In front of the ring there were two insulated spheres, which were so positioned that the ring just missed them as it turned on its needle. The spheres were either charged oppositely by the electrophorus, or only one sphere was charged, in which case the second sphere was grounded. The device operated on the same principle as Franklin's first motor.

Of all the motors discussed above, Franklin's original motors and the bell jar motor were the most powerful ones. One can make such motors even more powerful by increasing the number of moving and stationary electrodes. But this can be done only up to a limit, because if the electrodes are too close to one another, sparks will

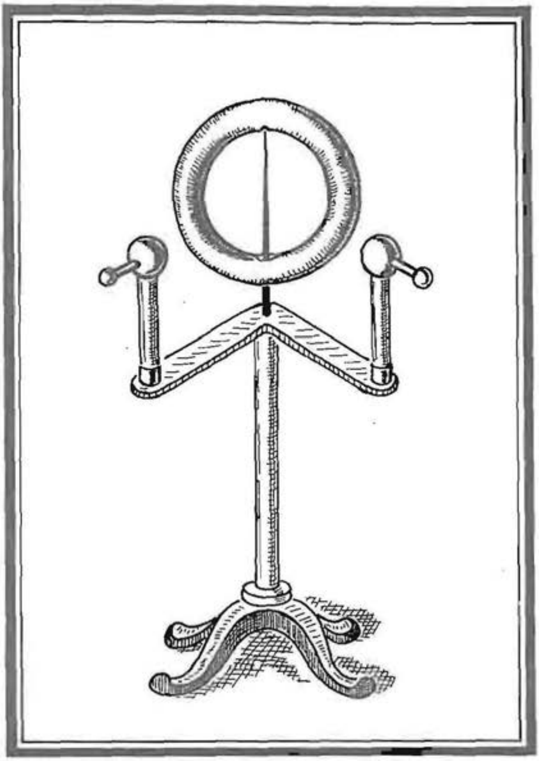

FIGURE 27

This motor derivable from Franklin's first motor and from pendulum motors was suggested for operation from an electrophorus.

jump all around from one electrode to the next, thus short-circuiting the motor. The motor will then not work at all, unless the operating voltage is lowered. But by lowering the voltage one also lowers the power, so that the gain obtained by increasing the number of electrodes becomes offset by the decrease in the operating voltage. Franklin type motors have therefore an inherent limitation in their power characteristics, and the fact that they depend for their operation on the presence of many metallic electrodes is one of their disadvantages.

Since in Franklin's motors and in other motors described in this chapter the rotor is charged by means of electric sparks, these motors may be classified as "spark motors". Toward the end of the 19th century a way was found to construct electrostatic motors based on the same mechanism of attraction and repulsion between electric charges as in Franklin's motors, but with rotors (or stators) charged more efficiently than it is possible to do by means of the sparks. These motors are described in the next chapter.

5

CORONA MOTORS AND MOTORS SIMILAR TO THEM

In 1867, W. Holtz, the inventor of the electrostatic "influence" machine (generator) carrying his name, discovered that this machine could function as a motor when powered by another similar machine.[1] In order to study this effect in some detail, the famous German physicist J. C. Poggendorff ordered the construction of a special device, analogous to Holtz's machine, but designed to operate only as a motor and provided with numerous adjustable components so as to operate under a wide range of conditions.[2]

The basic part of this motor was a vertical glass-disk rotor placed between two ebonite crosses carrying metallic sharp-needle "combs" (Fig. 28 and Plate 4). The sharp points of the combs almost touched the surface of the disk, so that the disk could be charged by means of a corona discharge from the combs when they were connected in alternation to an electrostatic generator. Each comb could be oriented so as to make an arbitrary angle with respect to a radial direction.

Just like the sparks in Franklin's motors, the corona discharge from a comb deposited on the rotor a charge of the same polarity as that of the comb. Each comb repelled therefore the segment of the rotor carrying charges which it sprayed onto the rotor and attracted the segment carrying charges sprayed onto the rotor by the preceding comb. Because of a continuous discharge between the combs and the rotor, almost the entire surface of the rotor was sprayed with electric charges. The repulsion and attraction between the combs and the rotor, were therefore not only much stronger than in Franklin's motors, (where only the electrodes were charged) but were also much steadier, since the distances between the combs and the charges on the rotor were always the same. As a result, the torque and power obtainable with this motor were far greater than those obtainable with Franklin's motors of similar dimensions.

Poggendorff made a thorough study of his motor, varying all its important parameters (his article comprises 32 pages). He used several rotors of different thickness and surface characteristics, whose weight ranged from 2.5 to 4.5 pounds (all rotors were 15 inches in diameter). He varied the number, the orientation, and the polarity of the combs.

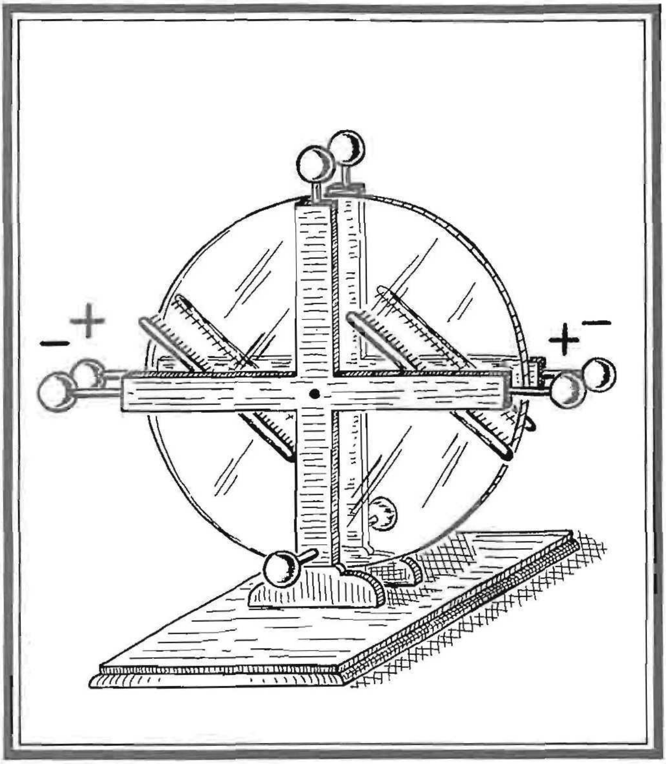

FIGURE 28

Poggendorff's corona motor had a glass-disk rotor placed between two ebonite crosses carrying metallic sharp-needle "combs".

He found that a motor with combs arranged along the radii of the rotor could rotate equally well in either direction but was not self-starting, since such combs sprayed charges onto the rotor in a perfectly symmetric fashion. However, if the combs were slanted relative to the radii, the motor became self-starting and unidirectional, because such combs sprayed charges predominantly in one direction. He also fould that the performance of the motor could be improved by placing pieces of glass, cardboard, or metal close to the surface of the rotor (this is the principle of the modern "backing plate" or "lining"; see Chapter 10). When properly adjusted, the motor could run at better than 300 rpm.

Poggendorff had fully appreciated the superiority of his motor in comparison fo Franklin's motors, and had stated so at the end of his article. In fact, he had indicated that his motor used from 1200 to 1800 times as much current as Franklin's motors, in which case, assuming that the operating voltage of his motor was the same as that of Franklin's motors (approximately 100 kilovolts), the power of his motor must have been close to 100 watts.

At the time when Poggendorff's article was written, however, it was considered unscientific to expect that electricity (*any* electricity) could ever become a significant source of motive power. This may be the reason why Poggendorff, speaking of the rotation phenomenon that he investigated, declared at the end of his article: "...it would be a sanguine hope if one wanted to believe that any useful mechanical effect could be achieved with it. That this is not possible, follows already from the consideration of how small is the quantity of electricity that is here put into play in comparison to that developed by a voltaic battery, with which one nevertheless, even with the help of the magnetismus produced by it, has so far achieved nothing substantial ("Erkleckliches")". The argument was obviously weak, but taking into account Poggendorff's reputation as an eminent scientist, it was probably sufficient to discourage further serious investigations of the corona-induced rotation for many years to come.

Since Poggendorff's motor depended on a corona discharge for its operation, the motor may be classified as a "corona motor".

Holtz's rotation phenomenon was also studied by the Danish physicist C. Christiansen (whose interest in the phenomenon had been aroused by a preliminary report of Poggendorff's investigations published in 1867).[3] Christiansen described two motors based on Holtz's discovery. His first motor consisted of a horizontal disk rotor and two stationary corona-producing combs. His second motor was similar to the first except that in it the glass disk was stationary and the combs constituted the rotor. The rotor combs in this second motor were located below the glass disk and were charged by means of two foil strips hanging from them and sliding along

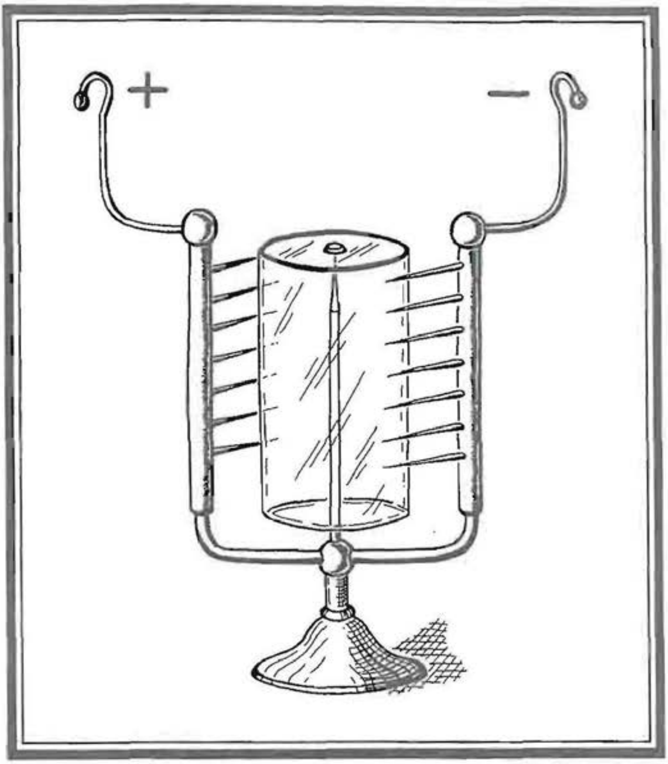

FIGURE 29

This self-starting corona motor with a cylindrical rotor was described in 1871 under the name of "electric tourbillion".

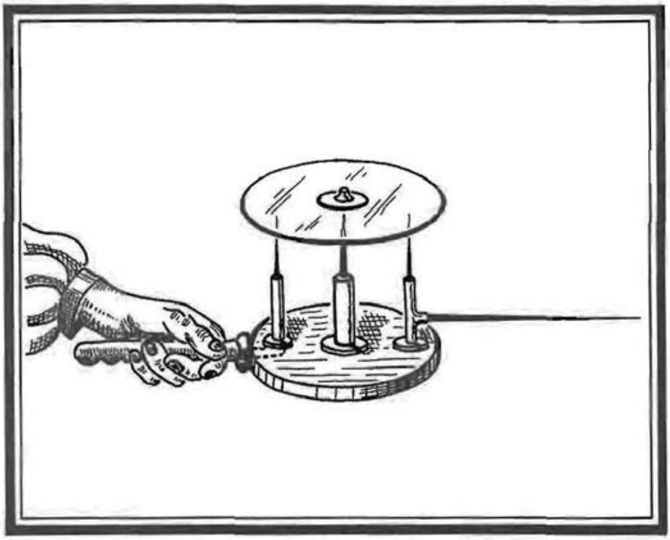

FIGURE 30

In this hand-held corona motor (attributed to Ruhmkorff) the horizontal wire, by a corona discharge, extracted charges from the power source, and the vertical needle connected to this wire, also by a corona discharge, sprayed these charges onto the rotor.

two horizontal concentric contact rings mounted on the base of the motor.

Cylindrical and spherical motors operating on the same principle as Poggendorff's motor were described in 1871 by W. Gruel (Fig. 29), who called them the "electric tourbillions".[4] Gruel pointed out that these motors could be made self-starting and unidirectional by inclining the combs in the same rotational direction with respect to the surface of the rotor. He also suggested that by providing the rotors with a series of holes, the motors could be used as sirens.

A disk motor not noticeably different from Poggendorff's motor was patented in the U.S.A. in 1891 by J. W. Davis and J. B. Farrington.[5]

An interesting hand-held corona motor (attributed to Ruhmkorff) was described in 1876 by M. E. Mascart.[6] The motor had a horizontal mica disk rotor (Fig. 30) supported on a vertical needle by a jewel bearing, such as are used for supporting compass needles. Below the disk there were two vertical corona-producing needles mounted on a hard rubber base. One of the latter needles was connected to a metal handle, the other was connected to a long, stiff, horizontal wire terminating in a sharp point. To set the motor in motion, the operator held the motor so that the sharp point of the horizontal wire was in the proximity of a charged conductor. By a corona discharge, the horizontal wire then extracted charges from the conductor, and the ver-

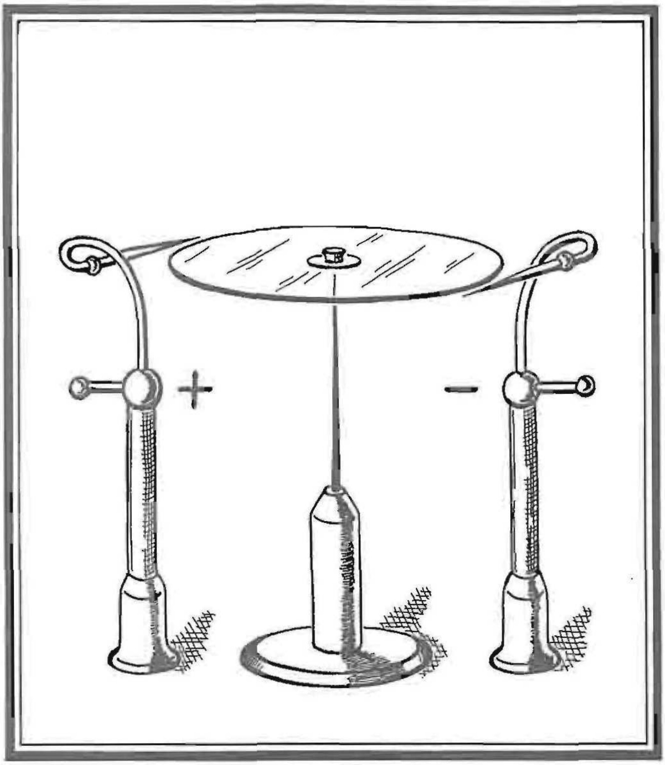

FIGURE 31

This motor had two insulated corona-producing points tangential to the rotor disk and oriented in the same rotational direction.

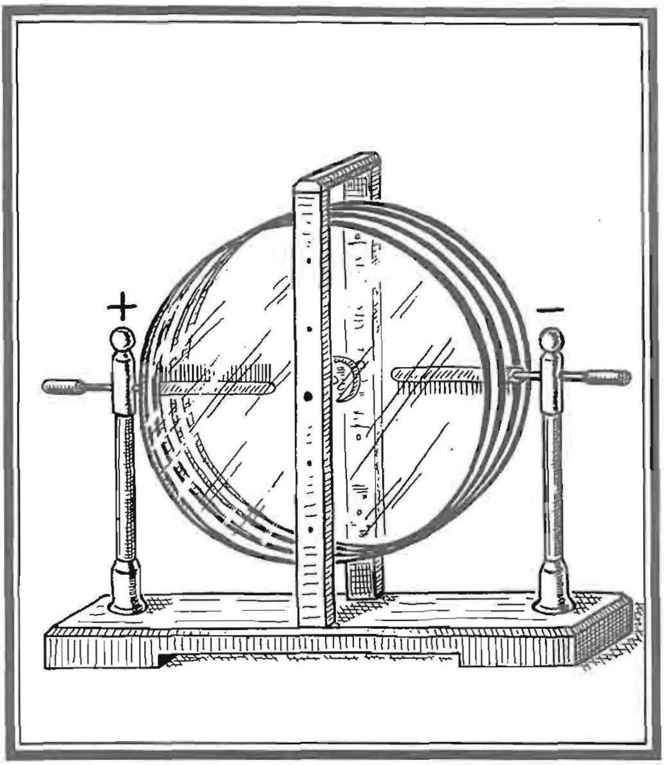

FIGURE 32

This corona motor with a compound glass rotor could run at about 2000 rpm and had a power of about 90 watts.

tical needle connected to this wire, also by a corona discharge, sprayed these charges onto the rotor. The second vertical needle discharged the rotor and conducted its charges to the ground through the hand and body of the operator.

A number of experiments with Poggendorff type corona motors were reported in 1921 by V. E. Johnson.[7] One of his motors was similar to Ruhmkorff's motor (Fig. 31). This was a horizontal mica disk, about 6 inches in diameter, supported on a vertical needle point. At the edge of the disk there were two insulated corona-producing points tangential to the disk and oriented in the same rotational direction. Another of Johnson's motors was a big machine consisting of two stationary glass disks and a three-piece glass rotor that could rotate on ball bearings between the stationary disks. The rotor was made of two large glass disks separated by a smaller disk so as to have a deep slot along its edge. Two flat sharp-point combs were inserted diametrically opposite to one another into the slot of the rotor (Fig. 32). Johnson estimated that his motor could run at about 2000 rpm and had a power of about 90 watts.

Just as Poggendorff's motor was derived from Holtz's electrostatic machine, a series of electrostatic motors were similarly derived from Wimshurst's electrostatic machine.

In 1891 five such motors were constructed by William McVay of New York City.[8] McVay's first motor (Fig. 33) consisted of two horizontal glass disks, about 12 inches in diameter, one stationary and the other rotating on the vertical axis just above the first. The lower disk had two quadrants of tinfoil, and the upper disk had 16 tinfoil sectors, as shown in the figure. The power (from a Wimshurst machine) was delivered to the motor by means of two insulated arms, each of which terminated in two brushes, one touching continually one of the lower quadrants, the other charging a sector on the upper disk just clear of the edge of the quadrant. Charges of the same polarity were thus deposited on the quadrant and on the sector, causing them to repel each other. An "equalizer" reduced the charge of the sectors before they passed over the further edge of an oppositely charged quadrant, thus reducing the back torque on the rotating disk. An important new feature of this motor was the simultaneous charging of the stationary quadrants and of the moving sectors, which assured a relatively strong starting torque and, together with the neutralizing system, assured a reliable unidirectional operation. McVay also constructed motors of cylindrical geometry, one of which is shown in Fig. 34. In this motor the quadrants were located on the inner cylinder, while the charging and neutralizing brushes were on the neck of the outside cylinder.

McVay's first motor was later modified for charging by combs, rather than by brushes (Fig. 35). The motor then operated essentially as

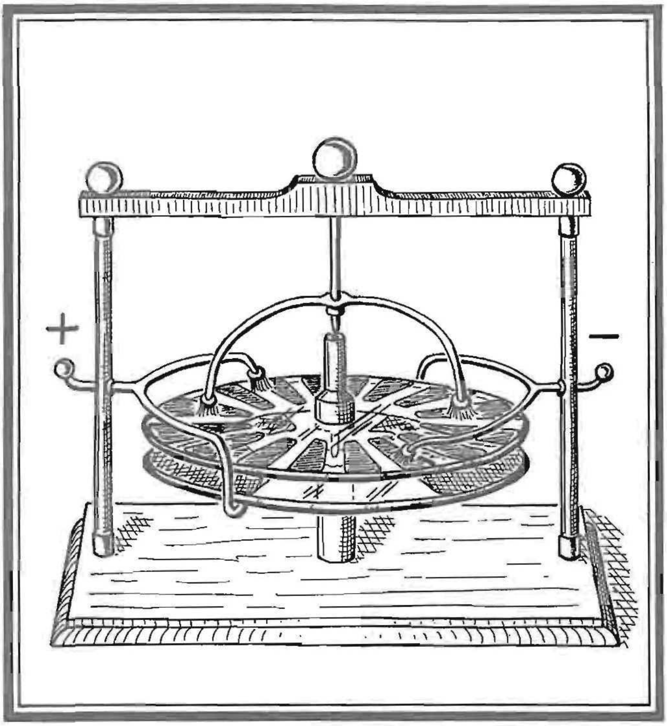

FIGURE 33

McVay's first motor consisted of two horizontal glass disks, about 12 inches in diameter, one stationary and the other rotating on the vertical axis just above the first.

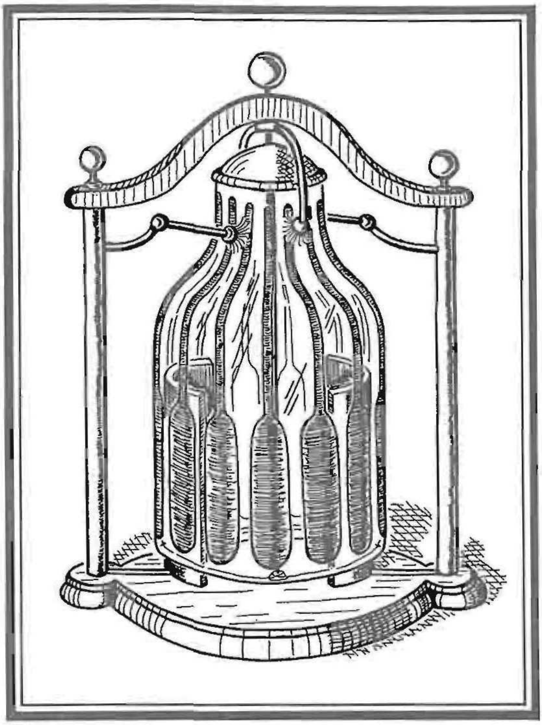

FIGURE 34
In this McVay's motor the quadrants were located on the inner cylinder (shown as two segments), while the charging and neutralizing brushes were on the neck of the outside cylinder.

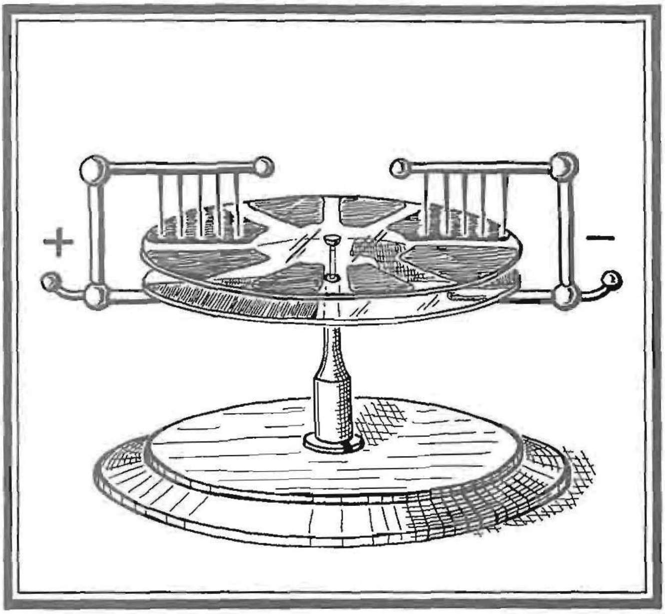

FIGURE 35

McVay's first motor was later modified for charging by combs, rather than by brushes. The motor then operated essentially as Poggendorff's corona motor, retaining, however, its self-starting and unidirectional qualities.

Poggendorff's corona motor, retaining, however, its self-starting and unidirectional qualities.

Instructions for building a Poggendorff motor may be found in the May 1971 issue of Popular Science.[9] Instructions for building a simple McVay motor may be found in the January 1914 issue of Electrical Experimenter[10] (the author is grateful to Mr. Thorn L. Mayes for this information).

Since a corona discharge in air at atmospheric pressure requires a minimum voltage of about 3000 volts, ordinary corona motors can operate only from sources capable of supplying a voltage of this magnitude. Such voltages are, of course, easily attainable at the present time, and since the corona motors are very simple and efficient devices, they have been further developed and studied in recent years. We shall return to them in the last chapter of this book.

CAPACITOR MOTORS

In 1889, Karl Zipernowsky, a Hungarian engineer (co-inventor of practical electrical transformers), constructed a new type of electrostatic motor,[1] which was derived from Thomson's quadrant electrometer.[2] The rotor of this motor (Fig. 36) consisted of two pairs of aluminum sectors insulated from each other and from the rest of the apparatus. The stator consisted of four double (hollow) sectors of brass enclosing the rotor. The rotor was fitted with a commutator in four parts, by means of which the sectors of the rotor were charged oppositely to those sectors of the stator into which they were entering and identically to those sectors of the stator which they were leaving. An interesting property of this motor was that it could operate from high-voltage dc as well as from high-voltage ac sources.

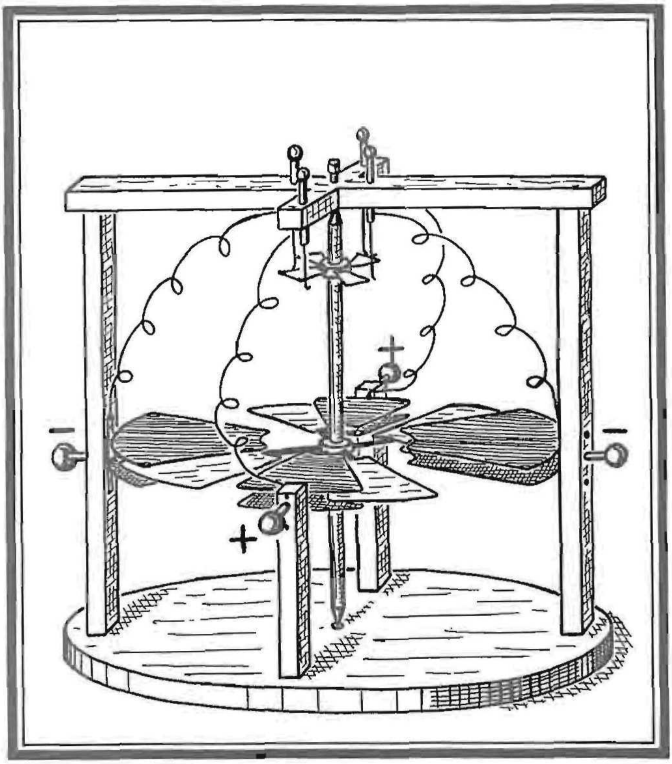

FIGURE 36

This motor was built in 1889 by Karl Zipernowsky, a Hungarian engineer. It operated from dc as well as from ac sources.

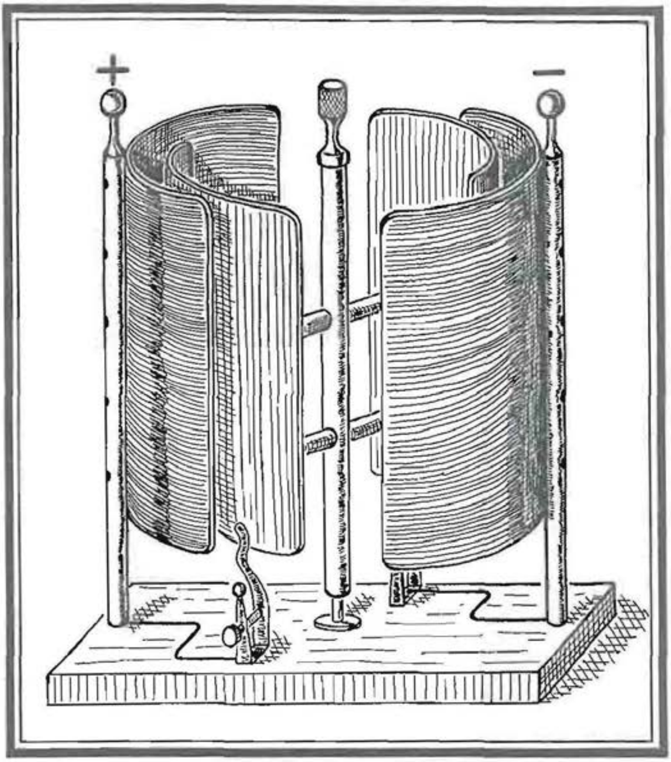

FIGURE 37

This capacitor motor was described in 1904 by van Huffel. Its rotor could be charged by contact or by sparks.

Inasmuch as Zipernowsky's motor operated as a result of the electric forces exerted by one charged conducting plate upon a second charged conducting plate (which are the same forces that act upon the two plates of a capacitor) it constituted what is now called an electrostatic "capacitor motor".

A simpler version of a capacitor motor was described in 1904 by van Huffel.[3] This motor was based on the so-called Thomson's replenisher.[4] The motor had an essentially cylindrical geometry (Fig. 37) and consisted of a rotor with two insulated bent brass plates mounted on a vertical axle and located between two similar, but slightly larger, plates of the stator. The rotor plates (which were not quite coaxial) were charged by means of two metallic tongues connected to the stator plates; the tongues touched the rotor plates just as the latter began to clear the stator plates. The charging of the rotor plates could occur by a direct contact as well as through a spark, depending on the adjustment of the tongues.

Since capacitor motors do not require sparks or a corona discharge for their operation, they can operate, at least in principle, from as low a voltage as one desires to use. This is one of their important advantages and is one of the reasons that such motors have been given considerable attention in recent years. Furthermore, as already indicated, capacitor motors can operate not only from dc sources, but also from ac sources. Finally, when powered by an ac source, they can operate both as synchronous and asynchronous motors (Zipernowsky's original motor operated from ac as an asynchronous motor).

A synchronous capacitor-type electrostatic motor is merely a multi-electrode capacitor motor without a commutator, the proper charging of the rotor being accomplished by continuously supplying an ac voltage of proper frequency between the stator and the rotor (Fig. 38). It is easy to see that if the rotor moves by one electrode in one period of the supply voltage, then the ac voltage accomplishes the same effect as that accomplished by a dc voltage with a commutator. The synchronous velocity is therefore $2\pi f/N$, where f is the frequency of the supply voltage and N is the number of the electrodes.

Several precision-made synchronous motors were described in 1969 by B. Bollée.[5] One of these motors ran on sapphire bearings and had a cylindrical aluminum rotor 1 centimeter long and 0.45 centimeters in diameter; the rotor and the stator had 60 electrodes each, with a 0.001 centimeter gap between stator and rotor electrodes. The maximum power of this motor was about 100 microwatts at 220 volts and 50 hertz. Another motor (for an electric clock) had a dielectric disk rotor, with four rows of 100 electrodes on each side, located between two bearing covers, each with five rows of 100 elec-

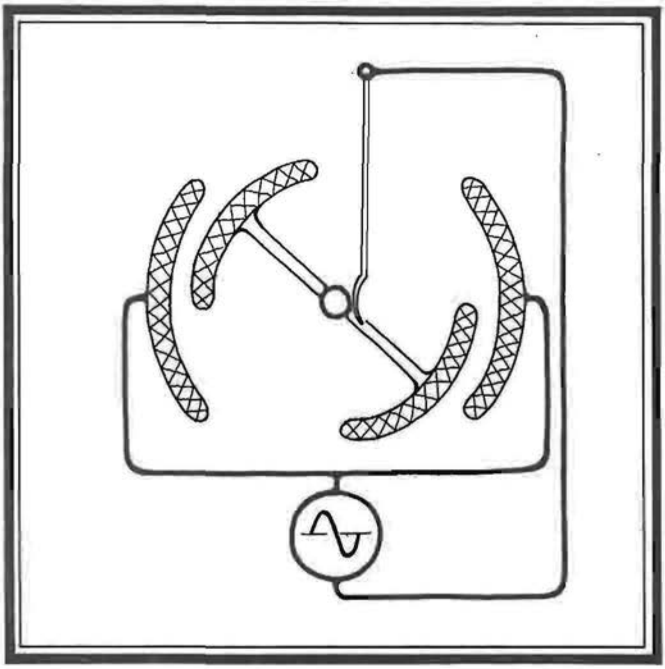

FIGURE 38

In a synchronous capacitor-type electrostatic motor the proper charging of the rotor is accomplished by continuously supplying an ac voltage of proper frequency between the stator and the rotor.

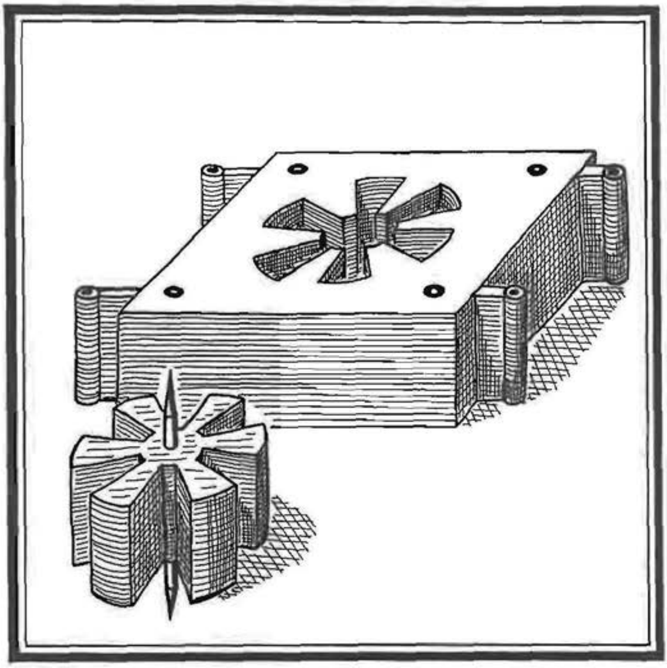

FIGURE 39

This synchronous electrostatic motor is essentially a variable capacitor with a rotatable shaft. The design of this motor is similar to the design of an electrostatic variable-capacitance generator.

trodes; the gap width in the axial direction was 0.01 centimeter. At 200 volts this motor had a maximum output of 600 microwatts. An interesting feature of this motor was that it had no slip ring on the rotor shaft, and that the rotor was therefore not connected to the power source. Instead, the stator was divided into two mutually insulated halves. This arrangement reduced the friction of the rotor and improved the performance of the motor. Still another motor was essentially a variable capacitor with a rotatable shaft. It had 15 plates in the stator and 14 in the rotor, each 0.03 centimeters thick; the gaps between stator and rotor plates were 0.015 centimeters (Fig. 39). The design of this motor is similar to the design of the electrostatic variable-capacitance generator described by N. J. Felici.[6]

According to Bollée, the maximum average torque on the rotor in a capacitor-type electrostatic motor is $T_{\max} = kNV^2$, where k is a geometrical constant, and V is the peak voltage applied. A motor with many electrodes is therefore slow but produces greater torque. The power of the motor is proportional to the square of the applied voltage and to the frequency but does not depend on the number of electrodes.

An important parameter in capacitor-type electrostatic motors is the capacitance difference $C_{\max} - C_{\min}$, where $C_{\max}$ is the greatest capacitance between the rotor and the stator and $C_{\min}$ is the smallest capacitance as they oc-

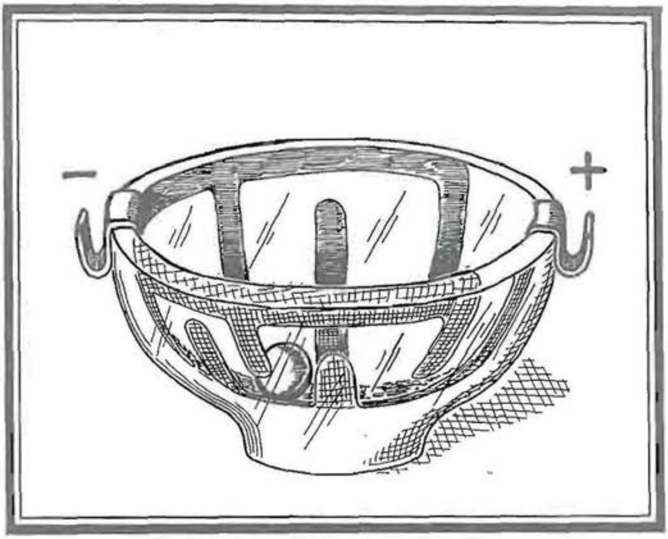

FIGURE 40

This interesting motor has been described by Moore, who calls it the "Interdigital Motor". The stator consists of a glass bowl with strips of aluminum foil glued to it. The rotor is a single conducting ball inside the bowl.

cur when the rotor turns. The larger this parameter is, the better are both the torque and the power. The main objective in the design of such motors is therefore to obtain the greatest possible variation of the capacitance.

An interesting motor which can be classified either as a modified Franklin's second motor or as a modified capacitor-type motor has been described by Moore,[7] who calls it the Interdigital Motor. The stator consists of a glass bowl with strips of aluminum foil glued to it (Fig. 40). The rotor is a single conducting ball inside the bowl; the ball runs along the sloping side when the strips are connected to an electrostatic generator (positive and negative strips are connected in alternation). Several balls can be placed into the bowl at the same time, and all of them will then run.

INDUCTION MOTORS

In 1892-1893, electrostatic motors of a fundametally new kind were described by Riccardo Arno[1,2] and by W. Weiler.[3] Their motors operated on the principle that the polarization of a dielectric in a variable electric field lags behind the field inducing the polarization. Therefore if a dielectric body is placed into a rotating electric field, the polarization charges* induced on the body will experience a force causing the body to follow the rotation of the field.

Arno's motor (Fig. 41) had a cylindrical stator formed by four insulated copper segments enclosing the space in which the rotating field was to be produced. The rotor was a hollow closed ebonite cylinder supported on two steel points turning in holes in glass; the cylinder weighed 40.33 grams, was 18 centimeters long and 8 centimeters in diameter. The rotating field was produced by means of a high-voltage transformer (3800 volts output), an RC-circuit, and a mercury commutator. The rotor attained a speed of about 250 rpm and developed a torque of 176 $\text{centimeter}^2 \times \text{gram} \times \text{second}^{-2}$.

---

*See, for example, O. Jefimenko "Electricity and Magnetism", Appleton-Century-Crofts, Inc. (1966), pp. 245-249.

Weiler used a hand-operated double commutator for his motors. The commutator delivered high voltage from an electrostatic generator in sequence to the four segments of a stator, thus producing the needed rotating electric field. Weiler described four different motors utilizing rotating fields. One of his motors was similar to Arno's motor. The operation of this motor (and that of Arno's motor) can be explained with the aid of Fig. 42, representing the top view of the motor. When segment A of the stator is positive, and segment B is negative, the electric field of the stator induces in the dielectric rotor (assumed to be at rest) polarization charges as shown in the figure. After the commutator has completed ¼ revolution, segment C is positive and segment D is negative. Thus the field has rotated by 90°, and now it polarizes the rotor in a new direction (at 90° with respect to the first). However, since it takes a certain time for the polarization charges to relax to zero, some of the initial polarization charges are still on the rotor, so that the distribution of the polarization charges on the rotor is not symmetrical relative

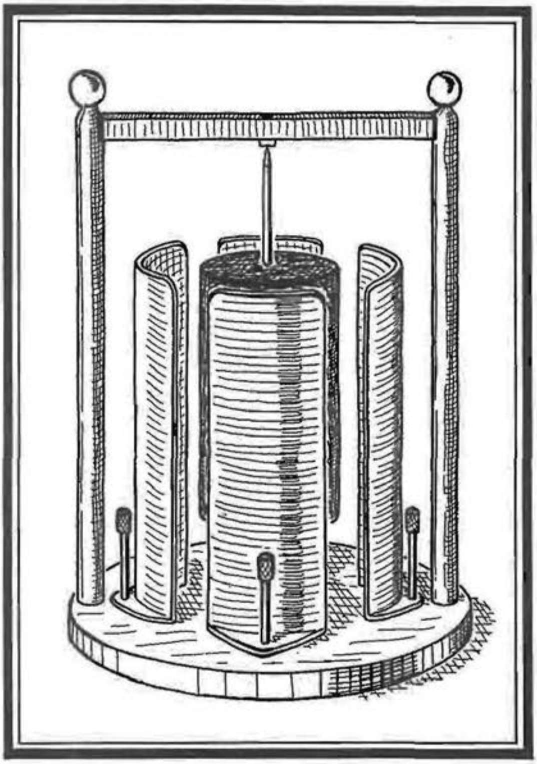

FIGURE 41

Arno's induction motor operated on the principle that the polarization of a dielectric in a variable electric field lags behind the field.

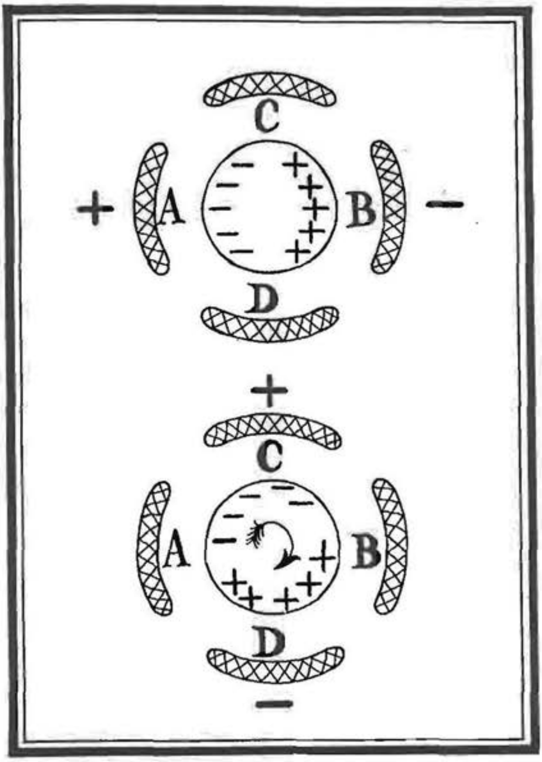

FIGURE 42

The operation of Arno's and Weiler's induction motors can be explained with the aid of this diagram.

to the charges on the stator. The rotor experiences therefore a torque due to attraction and repulsion between the rotor charges and stator charges, and the rotor turns.

Weiler also experimented with motors having noncylindrical rotors. One such motor is shown in Fig. 43. Rotating field electrostatic motors with disk-shaped rotors were built and studied between 1894 and 1901 in Japan by Hiderato Ho.[4]

Since Arno's and Weilers motors depend for their operation on induced polarization charges, they may be called "induction motors".

Induction motors, too, have a number of appealing features which attracted considerable interest to such motors in recent years: the motors can operate from both dc and ac; the motors can operate from low-voltage sources; since the motors require no brushes or slip rings, friction losses in these motors are very small.

Several carefully designed induction motors (both cylindrical and flat) were described in 1969 by Bollée.[5] One such motor of cylindrical geometry operated from a three-phase power supply at 220 volts and 50 hertz. The stator had 12 electrodes, which surrounded a rotor 15 centimeters in diameter. A disk-type induction motor operating from a three-phase power supply had a rotor consisting of 10 glass disks, each 6 centimeters in diameter, coated with a thin layer of slightly conductive material and mounted on a common axle. The rotor turned inside a ring

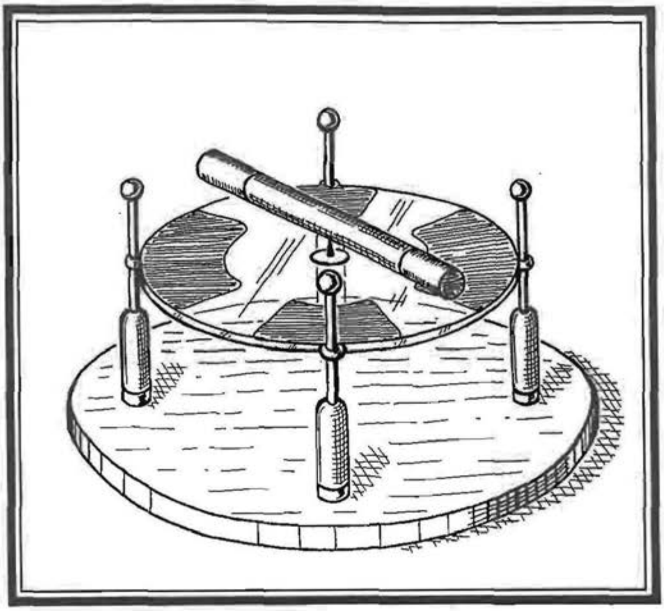

FIGURE 43

In 1892-1893, Weiler also experimented with induction motors having noncylindrical rotors, such as the motor shown in this drawing. Induction motors have a number of appealing features which attracted considerable interest to such motors in recent years.

formed by 60 comb-shaped stator electrodes. The maximum torque was 2000 centimeter^2 × gram × second $^{-2}$ at 220 volts and 50 hertz.

Another interesting motor described by Bollée was a linear induction motor, which "may be regarded as a segment of rotating-field motor bent straight".[5]

An extensive mathematical analysis of the induction motors was published in 1970 by Soon Dal Choi and D. A. Dunn.[6] They tested their theoretical results on a cylindrical motor with 72 electrodes. The motor was 14 inches wide, 14 inches high, and 19¼ inches long. It had a Plexiglas rotor that turned at a maximum rate of about 1000 rpm when powered by a 10-kilovolt source.

8

LIQUID-IMMERSED MOTORS

In 1893, W. Weiler discovered that a glass cylinder placed in a poorly conducting liquid between two spherical electrodes began to rotate when the electrodes were connected to an electrostatic generator.[1] He then constructed a small motor based on this discovery (Fig. 44). The principle of the operation of this motor was essentially the same as that of a cylindrical corona motor, except that the charges were now deposited on the rotor not by a corona discharge, but by the conduction current in the liquid.

In 1896, G. Quincke reported the same phenomenon and published a very comprehensive experimental study of it.[2] His device is shown in a simplified form in Fig. 45. It is interesting to note that Quincke, rather than Weiler, has been credited by subsequent investigators with the discovery of the rotation of dielectric bodies in

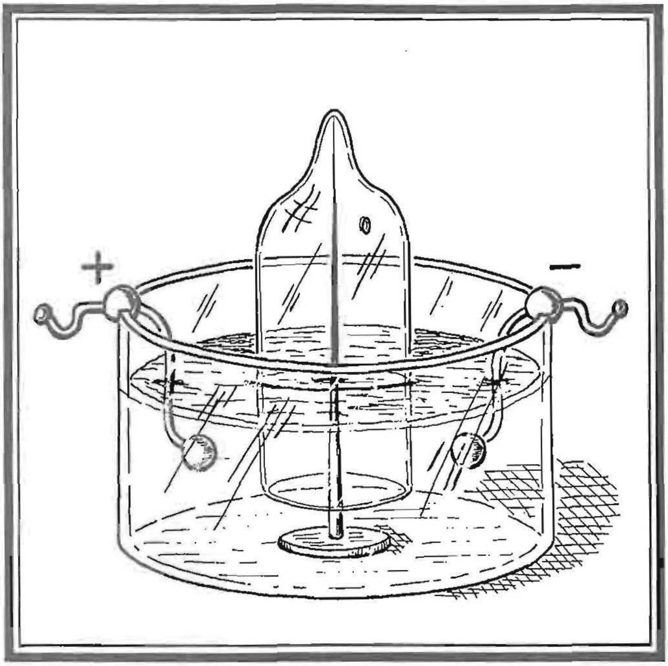

FIGURE 44

poorly conducting liquids.

Weiler-type liquid-immersed dielectric motors were recently studied in considerable detail by P. E. Secker and his co-workers.[3,4] Their motors operated in various semi-insulating liquids such as hexane, hexane doped with amyl alcohol or ethyl alcohol, and isoamyl alcohol.

In one of their motors the electrodes were stainless steel squares 1.8 centimeters on a side. Their separation was varied from 1 to 2.5 centimeters. The rotor, of ebonite or Perspex, was 0.95 centimeters in diameter and 2.2 centimeters long. The operating voltage was from 3 to 30 kilovolts. The speed of the motor was found to be a linear function of the applied voltage, with the maximum recorded speed of about 2500 rpm.

In another motor, a stator with six electrodes was used (Fig. 46). The rotor was made of Perspex and was 7/8 inches in diameter and 2 inches long; it had a layer of high-permittivity material on its surface (titanium ceramic in polystyrene). Powered by a 30-kilovolt source, the motor turned at 1700 rpm, and the total power input amounted to 5.4 watts, of which 2.7 watts appeared at the rotor shaft.

A discussion of electrohydrodynamic effects that may take place during an operation of liquid-immersed motors has been presented by J. R. Melcher and G. I. Taylor.[5]

Because of considerable hydrodynamical losses, the motors of this type will apparently always have a relatively low output torque.

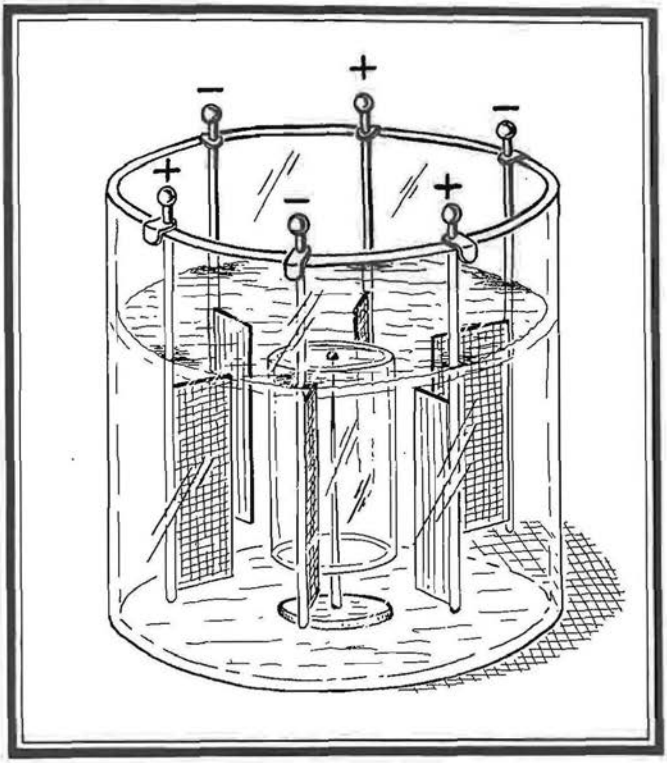

FIGURE 46

This liquid-immersed dielectric motor was recently studied in considerable detail by P. E. Secker and his co-workers.

9

ELECTRET MOTORS

In general, an electret is a permanently charged dielectric body. In a more restricted sense of the word, an electret is a permanently polarized dielectric body and may be considered to constitute the electrical counterpart of a permanent magnet. It is this latter type of electret that has been used for constructing electrostatic motors.

In 1961, the Russian physicist A. N. Gubkin described an electret motor[1] shown schematically in Fig. 47. The motor consisted of a stator formed by two horizontal, axially symmetric, parallel-plate capacitors and a rotor formed by two flat, axially symmetric, oppositely polarized electrets mounted on a vertical axle and capable of passing between the plates of the capacitors. The motor operated as follows. When a voltage was applied to the two capacitors, so that

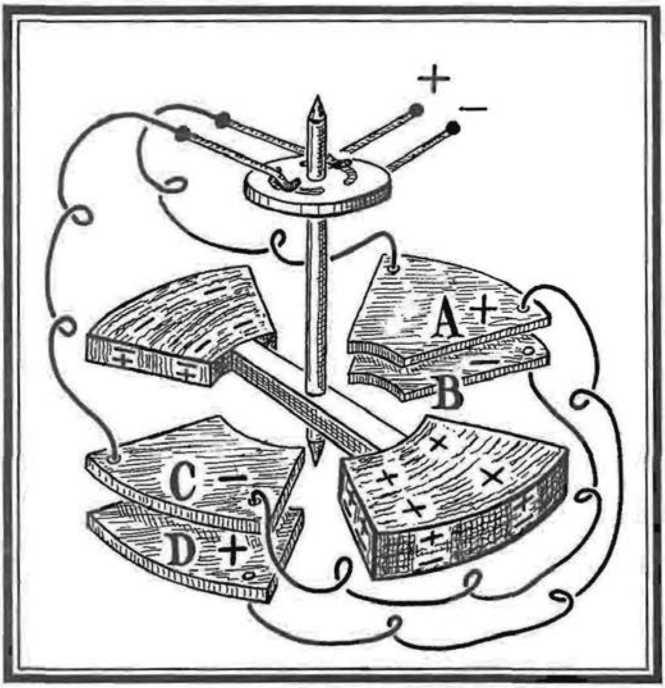

FIGURE 47

In 1961, the Russian physicist A. N. Gubkin described this motor with two electrets in the rotor and two parallel-plate capacitors in the stator. A commutator was used to change the polarity of the capacitors.

plates A and D were positive and plates B and C were negative, the capacitors attracted the electrets as soon as the latter came close to the plates, and the electrets were pulled into the capacitors. A commutator changed the polarity of the plates just as the electrets were coming out from the capacitors, and the electrets were then repelled from them, and so on. Thus the rotor was set in a continuous rotation.

A well-known property of electrets is that they lose their polarization in the absence of adequate shielding. Electret motors with almost perfect shielding were described by this author and by D. K. Walker in 1970.[2] These motors were based on the so-called "electret slot effect".[3] The slot effect works as follows (Fig. 48). An electret is placed between two pairs of electrodes, each pair forming a slot. If a voltage is applied to one or both electrode pairs, the electret (or the electrodes) experiences a force in a direction perpendicular to the slot and parallel to the plates. This arrangement insures both a nearly perfect shielding and a relatively large force.

A simple electret motor utilizing the slot effect is shown in Fig. 49 and Plate 5.* It uses a disk-shaped carnauba wax electret rotor consisting of two oppositely polarized half-disks. The stator has two pairs of electrodes connected to a

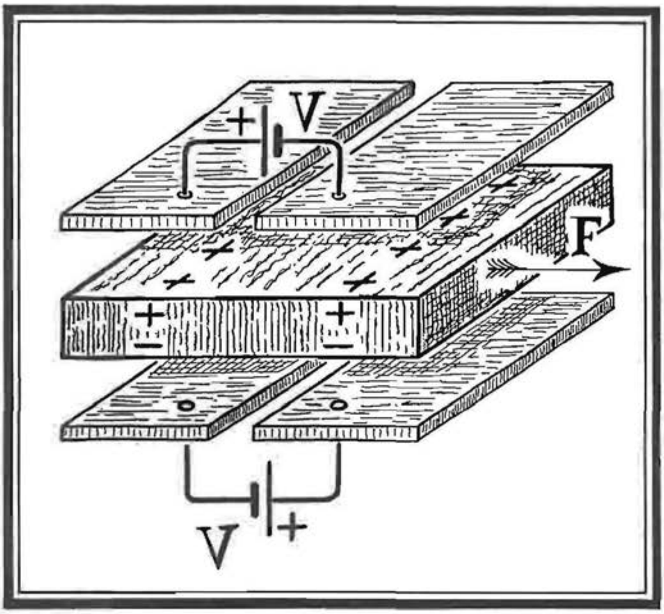

FIGURE 48

The slot effect works as follows. An electret is placed between two pairs of electrodes, each pair forming a slot. If a voltage is applied to one or both electrode pairs, the electret experiences a force in a direction perpendicular to the slot and parallel to the plates.

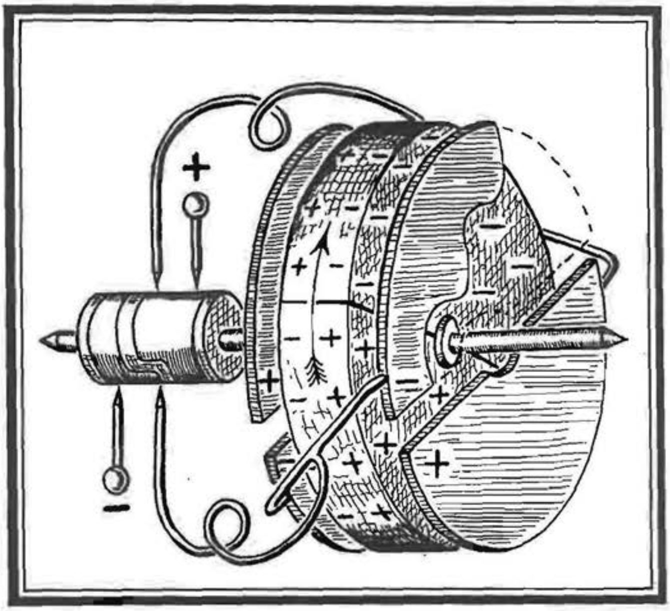

FIGURE 49

This simple electret motor utilizes the slot effect. The rotor is made of a disk-shaped electret consisting of two oppositely polarized half-disks. The stator has two pairs of slotted electrodes connected to a cylindrical commutator, which is charged by contact or by sparks.

cylindrical commutator. The thickness of the rotor is ½ inch, the diameter is 5 inches. The motor operates from an 8-kilovolt power supply and rotates at 1500 rpm.

Similar motors with stationary electrets and rotating electrodes are shown in Plates 6 and 7.

A more sophisticated slot-effect motor[2] uses a cylindrical electret (Fig. 50 and Plate 8). The electret is stationary; it is shaped as a hollow cylinder and has four sections of opposite radial polarization. The rotor is made of four internal and four external aluminum electrodes forming two cylinders with four slots in each. The inner electrodes are cross-connected with the outer ones, and all electrodes are supported by a Plexiglas disk mounted on a steel axle. This motor uses no commutator. The power is delivered to two adjacent external electrodes by means of two sharp points which charge the rotor through a corona discharge. The overall diameter of this motor is 3 inches, the operating voltage is 6 kilovolts, the speed is up to 5000 rpm, the power is about 20 milliwatts.

Synchronous electret motors for electric clocks have been recently announced by the General Time Corporation. The motors are about 1¼ inches in diameter and ¼ inch thick. In these motors (Fig. 51) a thin plastic electret disk with 15 active sectors and 15 equally large cut-outs is the rotor. The rotor is placed between two stator plates fabricated as printed circuit boards. Each stator plate has 30 elec-

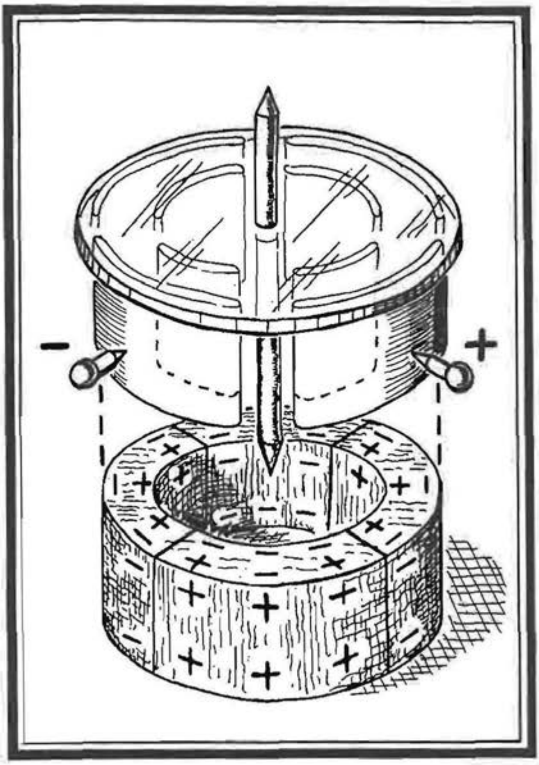

FIGURE 50

This more advanced slot-effect motor uses a stationary cylindrical electret and works without a commutator. The rotor has 8 slots.

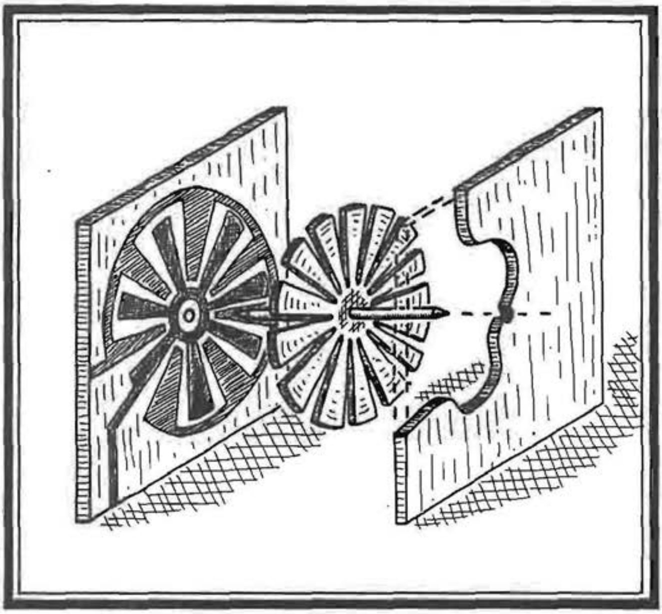

FIGURE 51

trodes connected in alternation to the two input terminals. The operation of this motor is similar to that of the first slot-effect motor described above (Fig. 49) except that the reversal of polarity of the electrodes is accomplished directly by the applied ac voltage rather than by a commutator.

Of all presently known types of electrostatic motors, electret motors are the newest and (together with corona motors) the most highly promising ones. We shall return to them once again in the next chapter.

10

WHAT TO EXPECT FROM ELECTROSTATIC MOTORS

Having described the various types of electrostatic motors we shall now present a brief discussion of the current aims in the electrostatic motor research and a brief discussion of the most probable future uses and applications of these motors.

It has been pointed out by Bollée[1] that electromagnetic motors rapidly lose their efficiency in scaled-down versions (which is due to the relative increase in energy dissipation in the magnet coils) and that very small capacitor-type and induction-type electrostatic motors may be a better choice for miniaturized systems. Therefore one may expect that miniature electrostatic motors of these types will find applications in various sensor and control devices where only very small torques and power are needed.

Experiments with electret motors conducted in the author's laboratory[2] indicate that these motors may be very useful in systems where powers of up to 1 watt are needed.

The most promising electrostatic motors appear to be, however, the corona motors. These motors possess a number of highly desirable features. Here are some of them: the motors are extremely simple in design; they require no expensive materials; their maintenance is very simple; having only few metal parts they possess a very good power-to-weight ratio; they are fully capable of developing appreciable amounts of power; and they can attain very high speeds.

Our present-day awareness of the many attractive properties of corona motors is to a great extent due to the work of the Russian engineers Yu. Karpov, V. Krasnoperov, and Yu. Okunev published in 1958 and 1960.[3,4] They described a 6-watt cylindrical corona motor of improved design (Fig. 52) operating from a 7-kilovolt power supply and turning at a rate of 6000 rpm. This motor had a hollow Plexiglas rotor 10.5 centimeters in diameter and 17 centimeters long with a conducting lining on its inner surface. The stator supported 16 knife-like electrodes inclined relative to the surface of the rotor in the direction of the desired rotation. The lining of the rotor served to increase the electric field in the gap between the electrodes and the surface of the rotor and thus to enhance the corona discharge from the electrodes.

A high-speed corona motor with a disk rotor

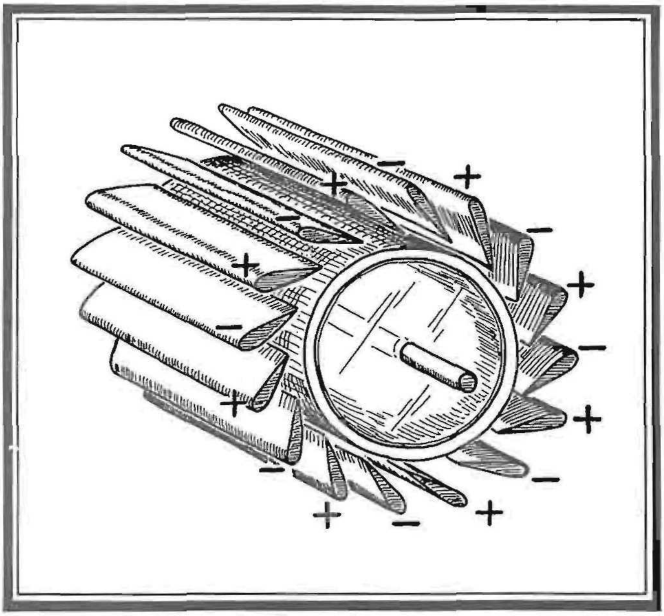

FIGURE 52

In 1958, the Russian engineers Yu. Karpov, V. Krasnoperov, and Yu. Okunev described a 6-watt cylindrical corona motor of an improved design operating from a 7-kilovolt power supply and turning at a rate of 6000 rpm. This motor had a Plexiglas rotor.

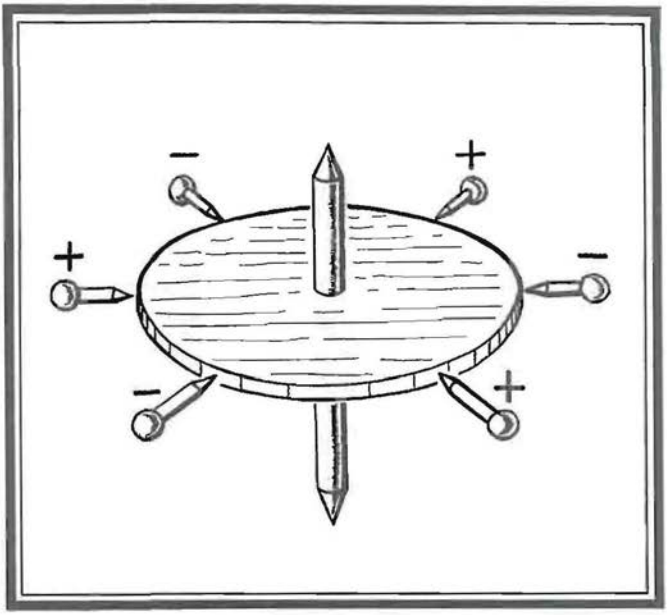

FIGURE 53

This corona motor with a disk rotor and circumferential electrodes was described by J. D. N. Van Wyck and G. J. Kühn of South Africa in 1961. It had a rotor 1.5 inches in diameter turning in jewel bearings. Operating from 13 kilovolts, the motor ran at 12000 rpm.

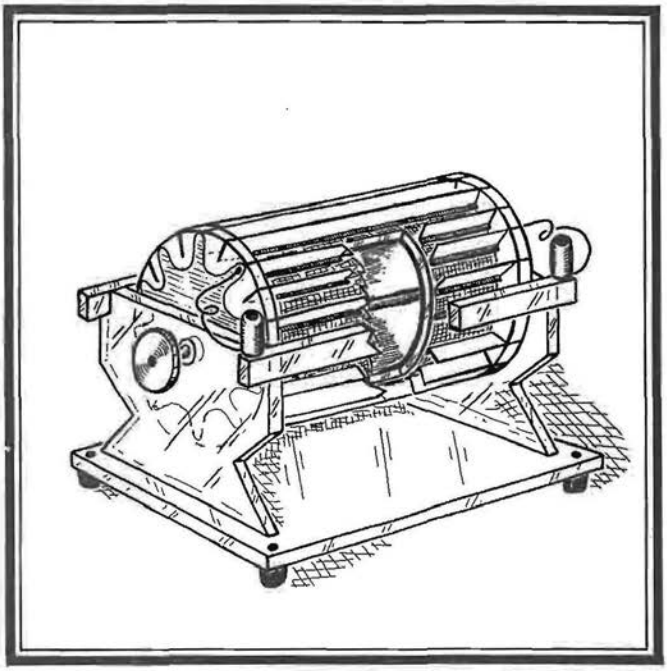

FIGURE 54

The performance of a corona motor depends on the shape and arrangement of electrodes and the structure of the rotor. The curved electrodes of this motor produce an especially large torque. The lining of the rotor increases the power.

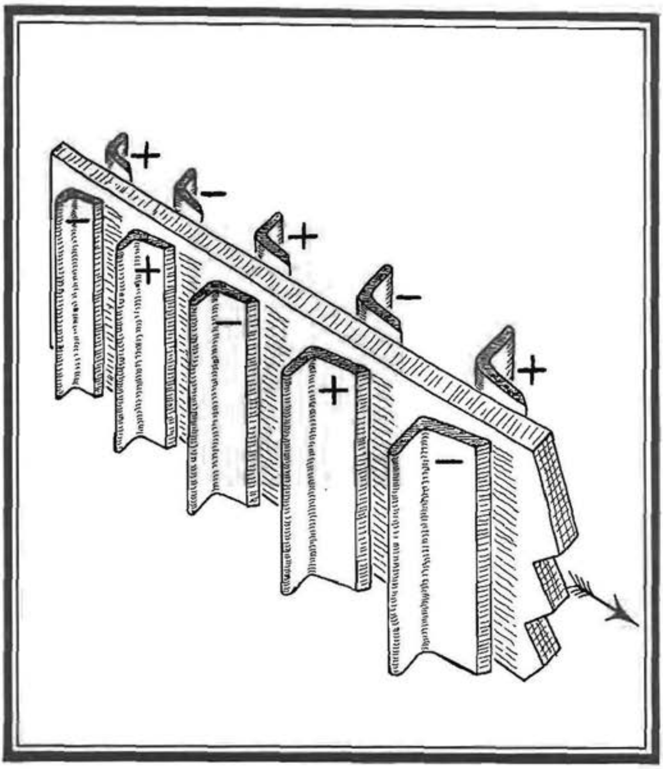

FIGURE 55

The mechanism of electric interaction producing rotational motion in corona motors can be used to achieve a translational motion as well. This drawing shows the principle of a linear corona motor with multiple electrodes.

and circumferential electrodes was described by J. D. N. Van Wyck and G. J. Kühn of South Africa in 1961.[5] The motor (Fig. 53) had a rotor 1.5 inches in diameter turning in jewel bearings. The stator supported 6 sharp-point electrodes. Operating from 8-13 kilovolts, the motor developed speeds of up to 12000 rpm.

A similar motor was studied in Poland by B. Sujak and W. Heffner in 1963.[6]

A number of advanced corona motors were studied in the author's laboratory;[7] an example of these motors is given in Fig. 54 and Plate 9. A diagram of a linear corona motor designed by the author is shown in Fig. 55. Instructions for building the corona motors of the author's design may be found in the May 1971 issue of Popular Science.[8]

It appears that corona motors with input power of 100 to 1000 watts and efficiency of at least 60% can be constructed without any difficulty. There seems to be no reason why even more powerful corona motors could not be built. It is likely that the motors can be further improved by using rotors immersed in a gas other than the air at atmospheric pressure.

Performance characteristics of corona motors strongly depend on the design and geometrical configuration of the electrodes spraying charges onto the rotor. Several typical electrode types and electrode configurations for corona motors are shown in Fig. 56. Especially interesting is the electrode arrangement shown in Fig. 56c.

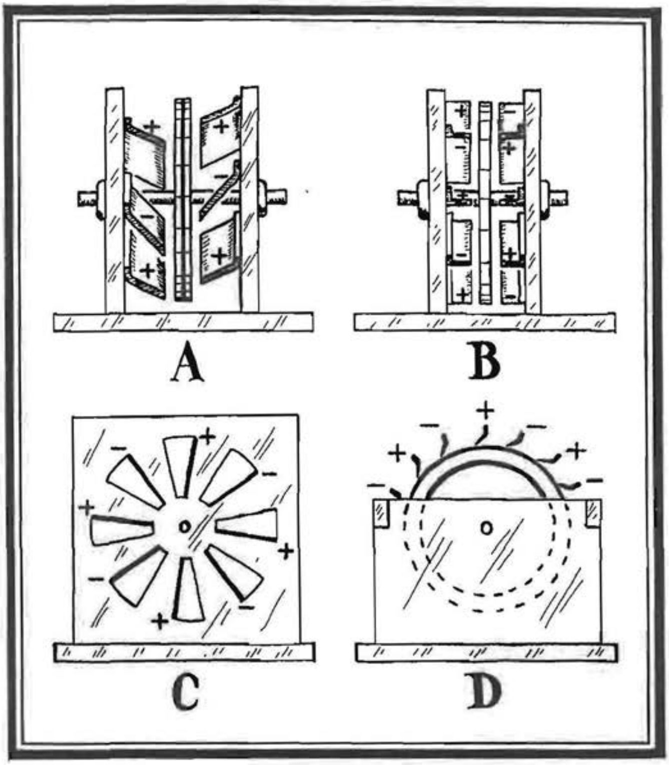

FIGURE 56

(a) Slanted electrodes and disk rotor with a conducting lining in the middle; (b) Straight electrodes; (c) Foil electrodes shielded on one side; (d) Curved electrodes and cylindrical rotor with a conducting lining.

This arrangement is used in conjunction with thin disk-shaped rotors "sandwiched" between two insulating stator plates. An even number of windows is cut in each stator plate, and metal foil electrodes are glued to the walls of the holes, as shown by heavy lines in Fig. 56c. In this arrangement there is a dielectric medium on one side of each electrode, and there is air on the other side. Therefore the electrodes spray charges predominantly in the direction of the side facing the air. Thus a motor with electrodes of this type is unidirectional and self-starting. Furthermore, the entire "sandwich" comprising the rotor and the two stator plates may be very thin. Therefore many such "sandwiches" can be placed on a single axle thus forming a compound motor in which good use is made of the entire volume occupied by the motor. There are indications that compound motors of this type can develop up to 1000 horsepower for each cubic meter of their volume.

An important property of electrostatic motors is that they can operate from a much greater variety of sources than the electromagnetic motors. It is, of course, obvious that any sources used for operating conventional electromagnetic motors can be used to operate the electrostatic motors. However, the electrostatic motors can operate also from sources from which no other motors can operate. The reason for this is that the electrostatic motors are extra-high impedence devices and thus require extremely small currents for their operation.

One very interesting source of electricity for electrostatic motors is the ordinary capacitor. It is true that capacitors, as we know them now, do not store appreciable amounts of electric energy. However, if high-permittivity low-loss dielectric materials were developed, then the capacitor would become a very useful device for storage of electric energy, and possibly could be used in place of the chemical batteries for operating electrostatic motors.

Another possible source of power for electrostatic motors are high-impedance high-voltage batteries of the type of Zamboni pile.

A potentially very important source of electricity for powering electrostatic motors are electrostatic generators. Considerable advances in the development of such generators have been made in recent years[9,10] and it is conceivable that electrostatic motor-generators will be used to convert the high-voltage dc produced by such generators into the conventional low-voltage dc or ac.

Finally, a very interesting source for powering electrostatic motors is the atmospheric electric field. In fact, it appears possible to extract the energy contained in this field by means of electrostatic motors. Experiments on such an energy extraction have been conducted by the author.[11,12] In these experiments an electret motor and a corona motor were powered by simple earth-field antennas (Fig. 57; Plates 10 to

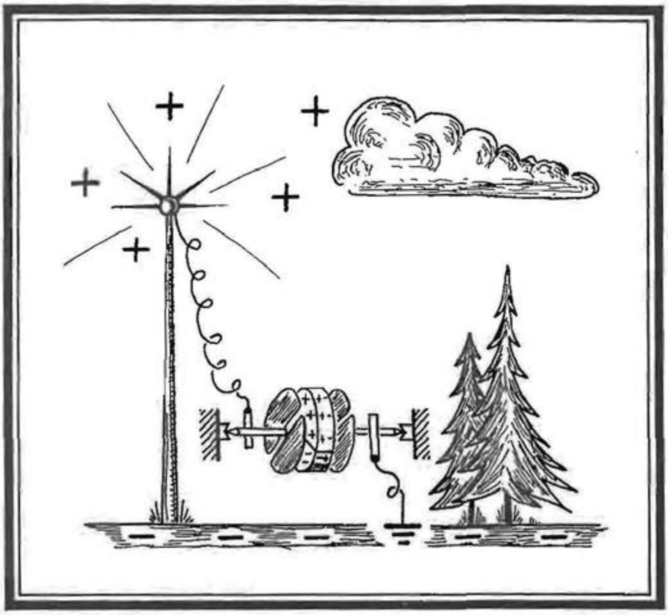

FIGURE 57

Small electrostatic motors can be powered from atmospheric electricity by means of simple earth-field antennas. Whether or not it will be possible to operate large motors in this manner will depend on how successful we are in designing antennas capable of extracting appreciable power from the earth electric field.

12). The corona motor was the one shown in Plate 9. The electret motor was similar to that shown in Fig. 49, but with the electret stationary and the electrodes rotating (Plate 6). These experiments indicate that it is entirely possible to operate small electrostatic motors from atmospheric electricity. Whether or not it will be possible to operate large motors in this manner will depend on how successful we will be in designing and building earth-field antennas capable of extracting appreciable power from the earth electric field.

In conclusion it may be useful to mention that a quantitative electrostatic motor research is now only in its very rudimentary stage. Almost all papers on electrostatic motors published thus far deal with the qualitative aspects of the performance of the various types of motors. Only very few papers deal with the optimization of design and with the quantitative aspects of the operation of the motors, likewise only very few papers present a theoretical analysis of the electrostatic motors. It is clear therefore that the electrostatic motors still constitute an essentially unexplored area of physics and engineering, and that the electrostatic motor research is presently one of the potentially most rewarding research fields in modern electrostatics.

Electricity from the earth's atmosphere. An old forgotten idea

Source: http://scienzaearte.blogspot.it/2011/03/energia-elettrica-dallatmosfera.html

Solar, wind, hydroelectric, geothermal, biogas. These are the main renewable and non-polluting energy sources. But sure not to leave something out?
It is known that the Earth's atmosphere has a potential difference that increases with height. For non-professionals it the atmosphere was a charged battery. This is evident during thunderstorms, when this charge finds its outlet in th frightening and fascinating phenomena that are lightning. Many have imagined and studied methods for storing ligh energy, but this presents numerous problems:

1) it is not known in advance where a lightning will strike or in any case where a thunderstorm will take place; 2) ev lightning strike could be intercepted, for example by attracting it with a kind of lightning rod, it would be extrem difficult to store all its energy, since the discharge is very short; 3) moreover, most of the lightning energy dissipat light, heat and sound. In short, a "power plant" based on the interception of lightning would not be very profitable. **W less known, however, is that the atmosphere has this charge even when there is not even a cloud in the sk**

. The idea of deriving electricity directly from the earth's atmosphere dates back more than a century ago. To m knowledge - I urge readers to post comments if they are aware of other studies - the latest and most promising study field was carried out by the Estonian engineer and inventor **Hermann Plauson** . His studies took place in the 1920 almost a century ago. Is it possible that since then there has been no progress in this field? Why did the idea of extra electricity from the Earth's atmosphere go into oblivion, even though it seemed promising at the time of Plauson's st

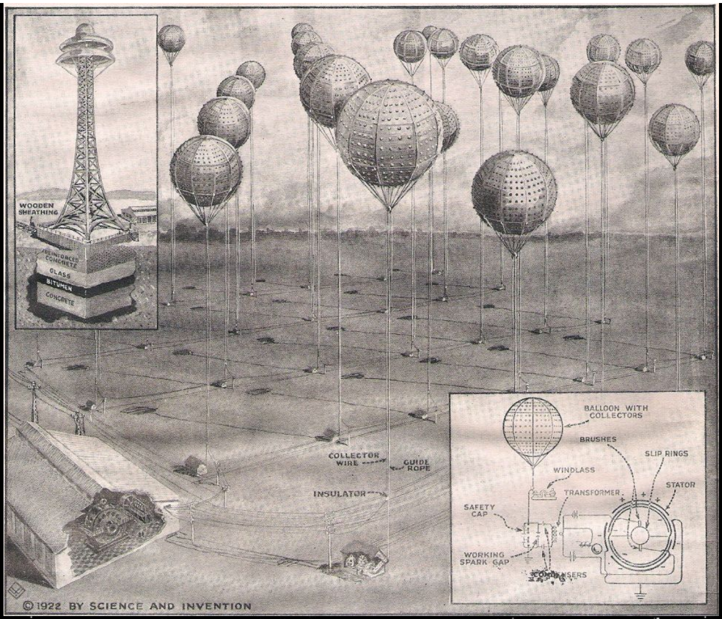

Image taken from the magazine "Science and Invention" (1922), where we describe the invention of Hermann Plau
Let's see before giving a brief description of the method used by Plauson. An electricity collector, consisting for exam
a balloon filled with helium, was raised to an altitude of several hundred meters, connected to the ground by a condu
cable. The balloon itself was made of conductive material and was covered with innumerable little needles, capabl
collecting atmospheric electricity through a phenomenon called field effect emission . High-voltage electricity w
conveyed to the ground by the conductor cable, and was converted into low-voltage electricity to be used by comm
electric users.

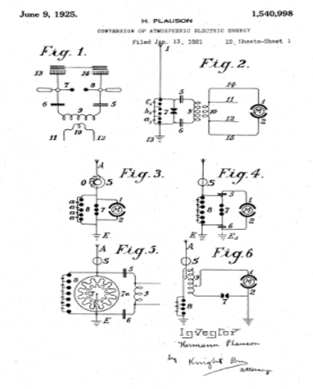
In the description of his invention , Plauson reports that he managed to get about 3.4 kW (kilowatt) in a "pilot" exper
using two of these balloons.
Returning to the first question: why such a promising technology was abandoned?
Several hypotheses can be made. The Plauson method provided - even if it was not bound - the use of radioactive ma
(radio and / or polonium), whose ionizing properties were used as a "catalyst" to increase the current inflow. It is ob
that today any alternative energy proposal based on the use of radioactive material would not be frowned upon,
considering the possible environmental impact that could result from accidental contamination. As a note
it is interesting *to mention* that until the eighties a type of lightning conductor covered with a thin layer of americiu
radioactive material), similar in concept to the Plauson collectors, was used in Italy: it is useless to say that these de
are currently become outlaws.
Another possible reason why the idea was abandoned may be related to the fact that the energy needs in the 20s wer
lower than today's ones: a typical "central" "at Plauson", composed of 100 separate balls the one from the other of a
100 meters (so 1 km of side), would have generated some hundreds of kilowatt: a power of all respect for those time
that pales a bit 'when compared to the energy produced by a single wind generator - about 1 Megawatt.
This reason, however, would justify only part of the abandonment of research in this field, since a system that allows
obtain even a few kilowatts using just a couple of balloons could be competitive - compared to wind energy - in area
windy and not served by the electricity network. **Let's** add at this point **an advantage that this system would hav
wind and solar: uninterrupted production 24 hours a day and 365 days a year** .
Apparently, therefore, the only major obstacle would seem to be represented by the use of radioactive material. And
we are meeting the recent technological development. In recent years, in fact, techniques have been developed to o
nanomaterials that are very efficient from the point of view of field effect emission: in practice they are super-pins
could function as effective collectors of atmospheric electricity without resorting to use of radioactive material.
Some might argue, and rightly so, "But are these particular nanomaterials safe from the health point of view?"
Unfortunately, since these are new technologies, it is still difficult to estimate the impact in this sense, but some studi
under way. If, as is hoped, these materials will be considered harmless to health, then it can not be excluded that t
research on electric energy obtained directly from the earth's atmosphere will find a new vigor and this source not
exploited can go alongside the best known renewable and non-polluting sources.
As a final note it should be added that even without using radioactive material and the nanomaterials mentioned abo

system similar to that of Plauson could provide modest but useful quantities of electricity, finding application especi
the areas of developing countries far from large centers inhabited.

Hermann PLAUSON

Conversion of Atmospheric Electricity

Source: Source: rexresearch.com



In 1920 the German engineer Hermann Plauson published a text "Gew und Verwertung der Atmospharischen Elektrizitat" (Acquisition and atmospheric electricity).

Where he concluded that atmospheric electricity could be captur exploited by men.

In this regard he wrote:

"Humanity will be free from worry about the threat of freezing death, knowing that in a pred time it will be possible to exploit the natural resources to the fullest ... Humanity will no longer suffer from the cold, because mother nature will give her abundant gift power."

Plauson designed a series of helium-filled balloons, able to collect atmospheric electricity in t through the use of thermionic rectifiers, Leida bottle condensers and induction coils, his idea supply energy to whole Germany.

Biography

Hermann Plauson was an Estonian engineer and inventor. Plauson investigated the production of energy and power via atmospheric electricity.

Plauson was the director of the Fischer-Tropsch "Otto Traun Research Laboratories" in Hamburg, Germany during the Weimar Republic of the 1920s. Nikola Tesla's idea for connecting machinery to the "wheelwork of nature". Plauson's US Patent # 1,540,998 methods of converting alternating radian electricity into rectified continuous current pulses. He developed the Plauson's converter, an electrostatic generator. In 1920, Plauson published a b *Production and Utilization of the Atmospheric Electricity* " (*Gr., Gewinnung und Verwertung der Atmospharischen Elektrizitat*). A copy of this boo British Library.

It is believed to be Gertrud Plauson (the exact relationship is unknown;

Power from the Air (I)

by

Hugo Gernsback

In the war there was developed in Germany in the new art --- or science --- that bids fair to revolutionize our present means of obtaining power.

This art, which is as new now as wireless, is 25 years ago, will be attainments during the next 25 years that may appear fantastic today. Hermann Plauso of the new science, has devoted years of labor to his researches and he has now been using small power plants, generating electricity direct from the a night, without interruption at practically no cost, once the plant is constructed.
We have occasion, to describe the system, roughly, from cabled dispatches, but complete information is available now. The amount of electrical power in our atmosphere is astounding. Herr Plauson found in his experiments a single balloon sent to a height of 300 yards gave a constant current at 400 amperes, or in 24 hours over 17-1 / 4 kilowatts! By using two balloons in connection with a special condenser battery, the power obtained was 81-1 / 2 24 hours. The actual current delivered was 6.8 amperes at 500 volts.

The best balloons used by the inventor are made of thin aluminum leaf. No fabric was used. A simple internal system of ribs, stays and wires, gives the b certain amount of elasticity. The balloon, when made airtight, is filled with hydrogen or better, with helium. It will then stay aloft for weeks at a time surface is made of extremely sharp pins, made sharp electrolytically. Ordinary pins did not test good current collectors, as they lacked extreme sharpnes themselves were made from amalgamated zinc, containing a radium preparation, in order to ionize the air. It was also found that by the outer surface of with zinc-amalgam. Even better results were obtained with polonium amalgam.

One hundred of these captive balloons, separated one hundred yards from each other, will give a steady yield of 200 horsepower. This is the minimum horsepower, due to the higher electrification of the atmosphere.

We need to go into the technic of how the problem is now solved by Herr Plauson. By using batteries of condensers, high tension transformers, etc., the be changed to any form desires. Such as lighting, running motors, charging storage batteries, etc.

Plauson also invented a sort of electrostatic rotary transformer which gives alternating current without the use of condensers and transformers. Indeed, very great, as it is actually sucks the current from the collector balloons. There is no doubt that this invention will become a universal use all over the wor see the land with captive balloons, especially in the country. Indeed, the time is not all that is coming from the atmosphere. It may be the least form of po as the cheapest form of power known today. Not only that, but not as devastating thunder storms occur

---

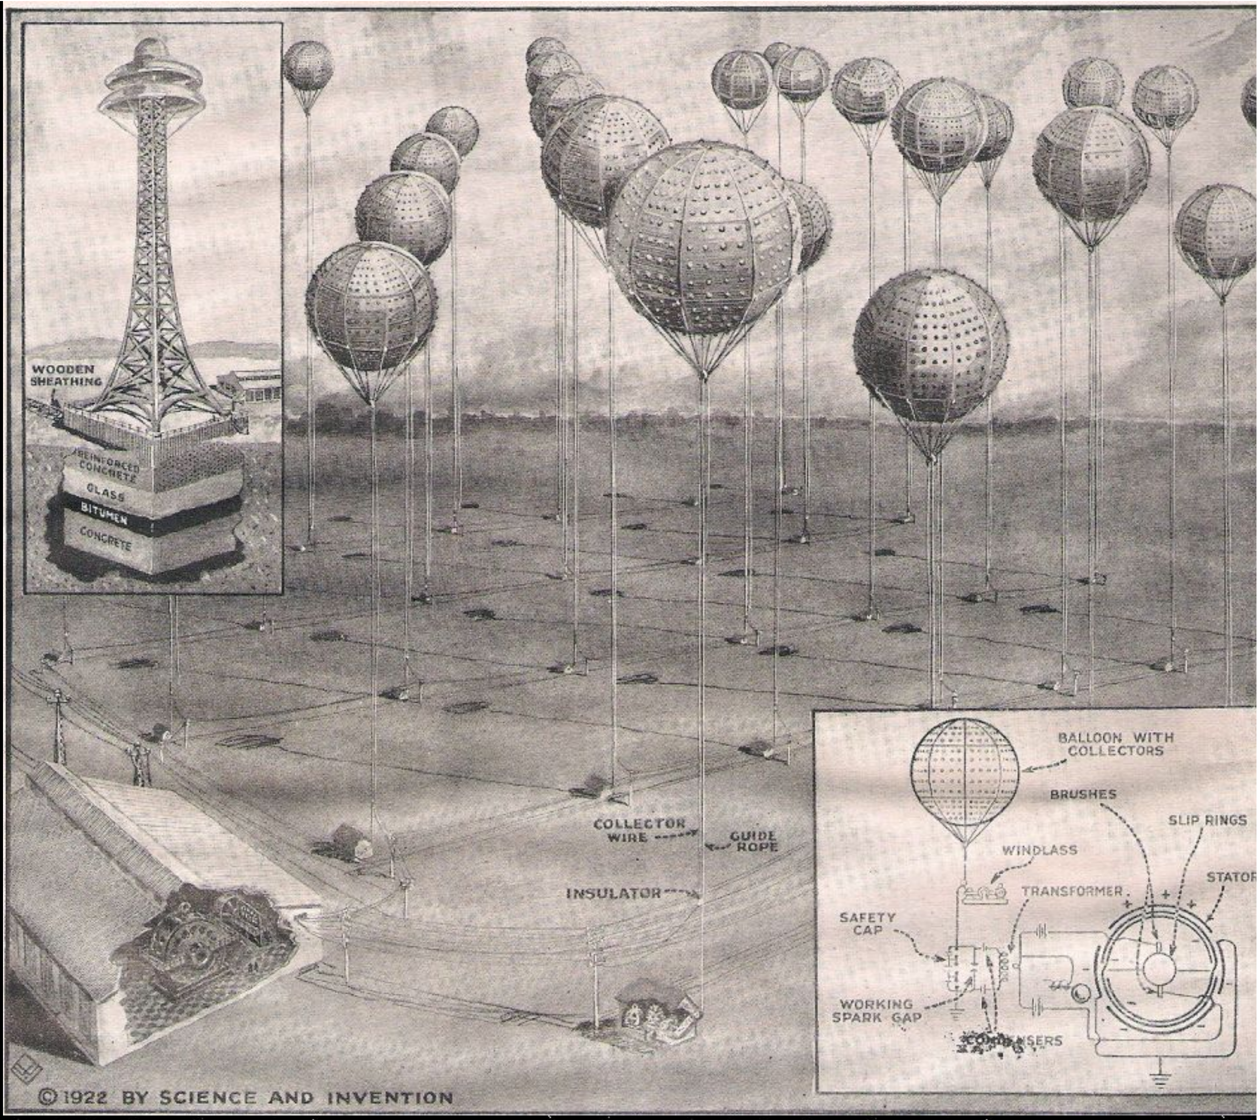
Power from the Air (II)

by

Hugo Gernsback

[For many years electrical engineers have been able to use the free electrical energy ever present in the atmosphere, but they were not the elevated co endanger the lives of the experimenters, or else destroy the apparatus connected with it. A German engineer has, however, devised the somewhat elabor here shown in the brief, and he has succeeded, at least so his report states, in safely extracting several kilowatts of electrical power from the atmos metallic surfaced balloons, elevated to a height of only 1000 feet.]



© 1922 BY SCIENCE AND INVENTION

We have been treated with the extraction of electrical energy from the atmosphere. The difference of the electric potential in different parts of the atmo
the difference between the upper air and the earth. The power would take the form of high potential. It has long appeared rather than to conservative e
such a source of power should really be available. It is not the same, but when the lightning flash is flashing, it is likely to be very small. seriously, as th
now being seriously investigated. A German scientist, Hermann Plauson,

We will first speak of the methods used for collecting electricity from the upper air. The author cites several German patents. One of them shows the u
balloon. The balloon is shown floating in the air, kite fashion, and from a great net or aerial for the collection of electricity. The conductor from the ae
the ground station; quite an elaborate description of the net-work which the patentee proposes to have covered with needle points. A windlass takes in
cable for the balloon, and the patentee claims that will send you to 225,000 volts to draw upon. He then speaks or a battery of 20,000 cells in series, wh
up to 40,000 to 50,000 volts in the charging. This certainly provides for a large large fall of potential.

But our author discards this idea and first suggest something more permanent. He proposes the erection of towers to the height of 1,000 feet. At the su
his collecting aerial. The appliance consists of a number of copper tubes; to the top of the tubes, with the aim of collecting net-work covering the tops o
"One of his apprehensions" should be his "trouble trouble", he would like to propose himself to "Siamese pagoda". He also compares the form of the pro
great petticoat insulator. His is insulated from the earth. He, therefore describes a complicated foundation for his structure. A foundation of simple concr
subject, it is a layer of cast glass, three to ten feet thick, and then comes to a reinforced concrete foundation. Sides of the ground, this foundation must
least seven feet The author's idea is based on the number of these towers connected by a horizontal cable. three to ten feet thick, and then to a reinforc
foundation, to which the metallic foot of the tower is to be anchored. Sides of the ground, this foundation must be raised at least seven feet The auth
based on the number of these towers connected by a horizontal cable. three to ten feet thick, and then to a reinforced concrete foundation, to which the m
of the tower is to be anchored. Sides of the ground, this foundation must be raised at least seven feet The author's idea is based on the number of th
connected by a horizontal cable.

The author strongly advocates balloons as collectors of the electric power of the air. These he depicts covered with spots. These spots indicate areas to be
coated and prepared to collect potential from the atmosphere.

In the first place he described the balloon as "made of thin metallic leaf" supported by internal ribs. Steel wires silver-plated, copper-plated, or alumin
run from the balloon to the pendant or junction ring. To this ring the cable is attached to the surface of the earth. 300 feet to three miles.

The coating of the spots is to be of the thinnest amalgam, of mercury and gold, or zinc, or even polonium, perhaps only 1/2500 inch thick. Numberless m
To prepare the needle-like wires, they are collected into bundles and are treated electrolytically in a bath, so as to be dissolved into part. This gives a shar
a roughened surface. The points may be of copper, steel, or some hard metallic alloy. After this corrosion. As it may be termed, the wires are plated w
other of the so-called noble metals. It is advised that polonium or radium salts be added to the plating bath.

Dr Plauson devotes This is a rotary motor including a stator and rotor and its peculiarity is that it contains no coils, develops no electromagnetic fie
speaking, but works by static excitation. One typical arrangement is shown in our illustration. The stator plates and rotor plates are concentric with
representing segments of cylinders. The alternation of negative and positive charged plates produces the rotation. In the connection there is included a s
gap to take care of dangerous potentials. Inductances and capacities are also used and indicated. The plates heated, owing to the Foucalt currents, are
subdividing the stator and rotor plates, are described by the author.

The whole subject is quite captivating, and it really seems as if the use of the air may be in sight. It would seem to be possible to carry out experim
direction by means of the Eiffel Tower.

And now our author gives us some practical details. He says that he is doing it with a radium preparation as an ionizer. The surface of the balloon wa
over with zinc amalgam. It was sent to a height of 300 meters, early 1,000 feet, and was held by a copper-plated steel wire. A constant current of 1.8 am
average of 400 volts potential difference was obtained. This gave nearly three-quarters of a kilowatt, or close to one horsepower. The collector of the ball
to be a tension of 42,000 volts. A passing a second balloon with an antenna. Antenna, and the antenna connection with the 500 volts mean tension. The k
the use of these two balloons.

By HENRY TOWNSEND

elevation of 350 ft., and these students of natural electrical phenomena have found a very desirable location in the Alps, where they can suspend between one mountain and an adjacent one, a strong iron cable having a length of about 2,000 ft. This cable is about 250 feet above the intervening valley, and from it these daring engineers have suspended a coarsely woven wire net, which serves as an electrical capacity to gather the electricity from the atmosphere. As shown in the pictures, the wire net is supplied with numerous sharp points to aid in collecting the current from the air.

As the accompanying photographs of the actual apparatus and wire cable used last year clearly show, an adjustable spark gap of considerable length is provided. By adjusting this spark gap to various lengths, it is possible to judge the voltage of the discharge which leaps the gap at any moment. Mr. F. W. Peek, Jr., the well-known American worker in the realm of high voltage measurements, together with other engineers, have provided tabulated data and curves for various lengths of both needle and sphere type spark gaps. As one of the accompanying diagrams shows, it is a simple matter to calculate the voltage when a certain length of gap is used. The engineer first checks the length of the gap on the chart; he then follows a line horizontally from the gap length, to where it intersects with the angular line on the chart; and from the point of intersection he looks in a visual line downward to a place where the voltage is given. For needle spark gap measurements, the characteristic curve on the chart is practically a straight line, while for sphere gaps the characteristic curve on the voltage versus gap length, is a curved line. Those interested in high voltage measurements by means of the spark gap method can find the voltage-gap tables and charts in the *Standardization Rules* of the American Institute of Electrical Engineers. According to Mr. Peek's researches, the voltage per foot of atmospheric electrical discharges is about 100,000, while in laboratory measurements with A.C., transformer high potential discharges, the average voltage per foot of spark was found to be about 150,000 volts. The voltage of a lightning flash may

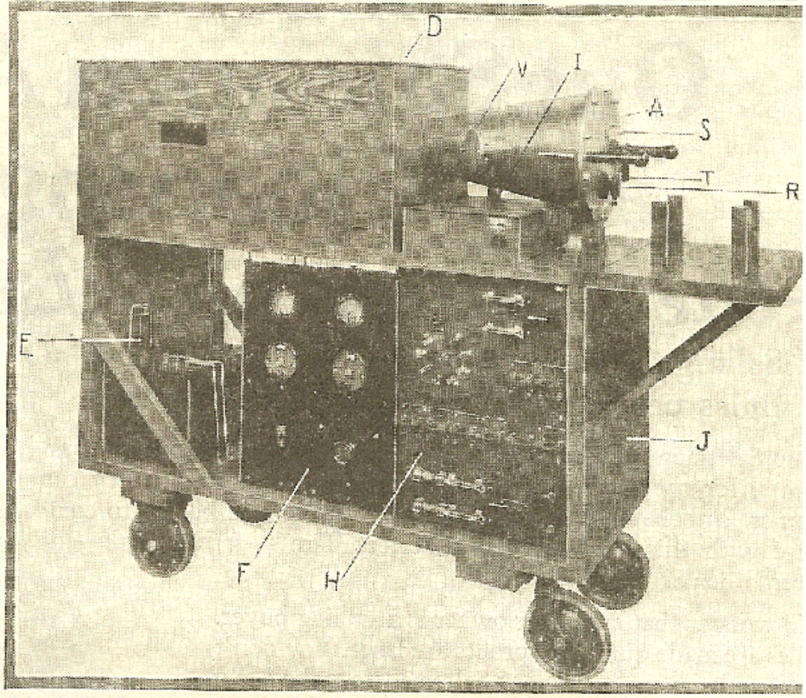
HARNESSING NATURE'S ELECTRICITY

By HENRY TOWNSEND

(*Continued from page* 111)



Remarkable cathode ray oscillograph used by Mr. F. W. Peck, Jr., in causing lightning t write its autograph with a pencil of electrons on a photographic film.

easily be 100,000,000 volts, as Mr. Peek has pointed out in one of his scientific papers.

WHY THE EXPERIMENTS ARE BEING MADE

ONE of the main reasons why these dangerous experiments are being carried on by the three young German scientists, whose names we have already learned, is because science believes that with a sufficiently high voltage, it will be possible for man to disintegrate the atom, and in this way make available a tremendous source of power as yet untapped. These experts have calculated that they will be able to obtain electrical energy in sufficient quantity from one of these powerful atmospheric discharges, to equal the Alpha rays obtained from 220 pounds of radium. As we have mentioned before, these experiments are of course fraught with great danger, and for that reason the experimenters seek refuge in a special lightning-proof hut, which is located about 600 ft., from the spark gap. When electrical storms are in the vicinity, it is especially important that the scientists keep within their protected fortress, for otherwise they would very probably be killed by a stray electrical discharge.

One of the peculiar things about this whole line of experiment is that the average layman does not realize perhaps, that there is a high electrical stress in the atmosphere on clear days, as well as when thunder storms are overhead. This fact has been known for a hundred years and more, and many years ago measurements of the various electrical potentials at increasing altitudes, were observed and measured by scientific investigators. There are a number of different ways in which these high electrical potentials found in the atmosphere can be measured; one of these methods involves the use of a calibrated spark gap. In this case the gap is set to a predetermined length, and when a discharge jumps this gap, the engineers know of course from previous experience and measurements, just what voltage is present. Another method of measuring
extra high potentials, such as here
countered, requires the use of a static v
meter, which involves the use of a statio
and of a movable or rotary set of m
plates, forming a condenser, to which
indicating needle is attached. For volt
above 2,000, static voltmeters have been
in a great many American central stati
and they have many desirable and us
characteristics. Of course as the vol
to be measured increases, the space betw
the quadrant shaped stationary and mov
plates is increased and vice versa.
electrostatic field from voltages below 2
is not sufficient to warrant the use o
static voltmeter. Another method of m
uring high potentials involves the use
the so-called vacuum tube voltmeter.

The general characteristics of the
mospheric electrical discharges, inclu
lightning, have been measured and reco
by one of the newest scientific instrum
known as the cathode ray oscillograph.
means of this quite remarkable, high
age scientific apparatus. Mr. Peck, one
the well-known General Electric Comp
staff of research engineers, has made s
very interesting and remarkable discove
concerning the nature of natural elect
discharges, particularly of lightning
charges. Many people will probably wo
why Mr. Peek and some of his collea
in the engineering profession, including
three daring German students, Mes
Brasch, Lange and Urban, play with
dangerous electrical discharges, and
they are at all interested in them. We
plained previously why the German sav
are intent on finding out all they can a
these tremendous voltages obtained
the atmosphere, while Mr. Peck, we
say, also has a very practical reason
carrying on experiments with these de
dealing bolts of Thor. Mr. Peek has
for many years intent on finding out
causes the huge insulators on long dista
high potential transmission lines to b
down when electrical storms break loose
these regions.

Atmospheric Electricity Research
[Excerpts]

In the nineteenth and early twentieth centuries, a large number of investigators

Dr Hermann Plauson who in the 1920s succeeded in generating significant quantities of electrical power with modern solar photovoltaic systems of a s
...

Dr Hermann Plauson. Dr Plauson was an Estonian citizen who lived in Hamburg and Switzerland. He carried out experiments in Finland with ma magnesium-aluminum alloys, covered with electrolytically deposited needles. The needles were further doped with a radium compound to increase the i the air. (This was the era in which the hands were painted with radium to make them luminous in the dark). Zinc amalgam patches were also paint aerostats. Plauson obtained with power output of 0.72kW and 3.4kW from one and two aerostats 300m above ground level. Dr Plauson filed patents i Great Britain and Germany in the 1920s. His book "Gewinnung und Verwertung der Atmosphärischen Elektrizität"

Other atmospheric electricity researchers contemporary to Dr Plauson included Walter Pennock and MW Dewey in the USA, Andor Palencsar in Hung Heinrich Rudolph in Germany. Hippolyte Charles Vion in Paris predated them all, putting forward proposals in the 1850s and 1860s.

Heinrich Rudolph made an interesting contribution to the design of the aerostat collectors. In 1898 he designed an elliptical aerostat made up of faceted minimize the effect of wind. The design bears a strong resemblance to Northrop's 2003 UCARS unamnned helicopter UAV project. The design uses Effect to help keep the aerostat on station and minimise wind effects.

Dr Oleg Jefimenko: In recent times, Dr Oleg Jefimenko has been active in this field. Dr Jefimenko carried out experiments on electrostatic motors from the 1970s.

MIR's Research Program

Since 1997 we have been carrying out theoretical research into conversion of atmospheric electricity into useable electrical power.

From a low level (5m high) simple zinc antenna we are able to obtain sufficient charge. Further experimental investigations with metallic aerostat col cavity resonant slow-wave antennae concepts are ongoing ...

Advantages of Atmospheric Electricity

Simple and robust technology
Low Cost Technology - much cheaper than photovoltaics or wind turbines
Available day and night in all weather conditions - in fact, blackberries power is produced at night than during the day
Available at any point on the Earth's surface

Conversion of Atmospheric Electric Energy

(9 June 1925)

Hermann PLAUSON

Be it known that I, Hermann Plauson, Estonian subject, residing in Hamburg, Germany, have been invented in the Conversion of Atmospheric Electric Ene following is a specification,

A method of obtaining atmospheric electricity by means of metallic nettings set with spikes which are held by means of ordinary or anchored kite balloons m filled with hydrogen, are in theory already known. Direct current for the charging of accumulators. This knowledge is only presented as theoretical as the conv has hitherto been a failure. Apparatus of destruction by lightning. The balloons used for collecting the charge must also be made of very large size.

Non-conducting materials of non-conducting materials that are liable to be used as non-conducting materials

(a) The metallic cases are impenetrable to helium and hydrogen; they also represent large metallic weather-proof collecting surfaces.

(b) Radio active means the like may be easily applied internally or externally; whereby the ionization is considerable increased and there is also the quanti electricity capable of being collected.

(c) These balloons have been produced by light weight.

(d) The entire system offers a small surface for the action of storm and wind.

(e) Each balloon can be raised and lowered by means of a winch so that all repairs can be carried out without danger during the operation.

Collaterals are interconnected by electrical conductors.

This article was previously published underneath this article. strength is converted into electro-dynamic energy into the form of high frequency vibrations. Ma make the purchase and all disadvantages avoided.

This article is based on the current law. It is possible to obtain electromagnetic waves of various amplitude and to increase the degree of resonance of suc resonance can be used to provide the possibility to be chosen again by the starting and stopping of the machine by simply transforming the resonance betwee machine and the transformer forming the resonance. Further, such currents have the property of being directly available for various uses, even without em driving motors, of which there may be

Further, with such currents a series of apparatus may be fed without direct current supply through conductors and also the electro-magnetic high frequency converted by means of special motors adapted for electro-magnetic oscillations into mechanical energy, or finally converted by special machines into alternatin

The invention is more particularly with reference to the accompanying diagrams in which:

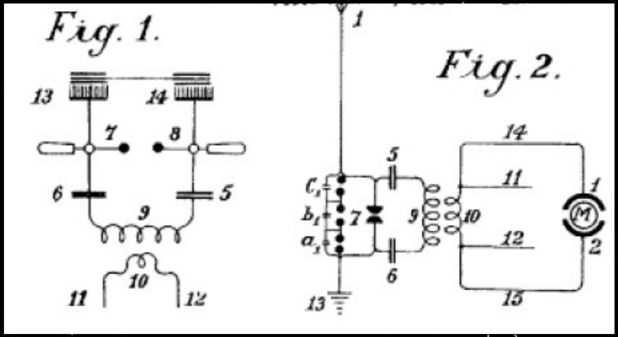

Figure 1 illustrates a simple diagram for converting static electricity into a dynamic power of a high number of oscillations. An illustration of an influence ma of clarity. 13 and 14 are combs for collecting the static electricity. 7 and 8 are spark discharging electrodes. 10 and 8 inductive coil, 10 secondary coils, 1 conductors of the secondary coil 10. When the disc of the static influence is rotated by mechanical means, the combs collect the electric charges one the and and 6 until the potential is formed across the spark gap 7-8, that the spark gap is jumped. As the spark gap 7-8 forms a closed circuit with condensers 5 and 6,

The high frequency of the oscillations produced in the primary circuit. Thus in the primary circuit electromagnetic oscillations are formed by the passage of the

The ratio between the number of the coils in the primary and the secondary circuits with the correct use of the co-efficients of the resonance (especiall resistance) voltage and high current strength.

The liquid gap until the accumulated charge again breaks the spark gap. This is how it is produced by the static machine employing mechanical energy.

Figure 2 in which two spark gaps in parallel are shown in Figure 2, while the second one is used as a safety device for excess voltage and consists of a larger in series and are bridged by very small capacities as shown in a, b, c, Figure 2

In Figure 2, it is an aerial antenna for collecting charges of atmospheric electricity. 13 is the earth connection of the second part of the spark gap, 5 and 6 are primary coil. Now when you go through the aerial The spark gaps. The resistance of the spark gap is shown in the drawings, lower than that of the other safe consists of three spark gaps connected in series, and consequently to three times.

So long, therefore, as the resistance of the spark gap, I know that the other spark gaps have an equal resistance with the discharges take place it could be dange the condensers 5 and 6 for the coil insulation 9 and 10 in consequence of the break down, by a correct regulation of this spark gap .

Without this second spark gap, it is impossible to collect and make available large quantities of electrical energy.

; Capacitor 5 and 6, primary coil 9, and also secondary coil 10 is the same as the one described in Figure 1 with the arrangement of the static induction mach difference that here the second spark gap is provided. The electromagnetic high frequency alternating current can be tapped off from the conductors 11 and 1 heating purposes. Special kinds of motors with special features such as electrical systems may be connected to 14 and 15 which can work with static e frequency oscillations.

In addition to the use of spark gaps in parallel a second measure of security is also necessary for taking off the current. This is a precautionary measure based in the introduction of a method of connecting certain protective electromagnets or choking coils in the aerial circuit as shown by S in Figure 3.

A single electromagnet only having a core of the thinnest possible separate laminations is connected with the aerial.

In the case of high frequencies in the aerial network or at places where there are frequent thunder storms, several such magnets may be connected in series.

In the case of parallel or parallel series.

The windings of these electromagnets may be connected in series with the aerials. In this case the winding preferably consists of several thin parallel wires together, the necessary section.

The winding may be made of primary and secondary windings in the form of a transformer. The primary windings will be connected in series with the aerial secondary winding is more or less short-circuited over a regulating resistance or an induction coil. It is possible to regulate to a certain extent the effect of the c aerial electromagnet choke coil is indicated by a simple ring

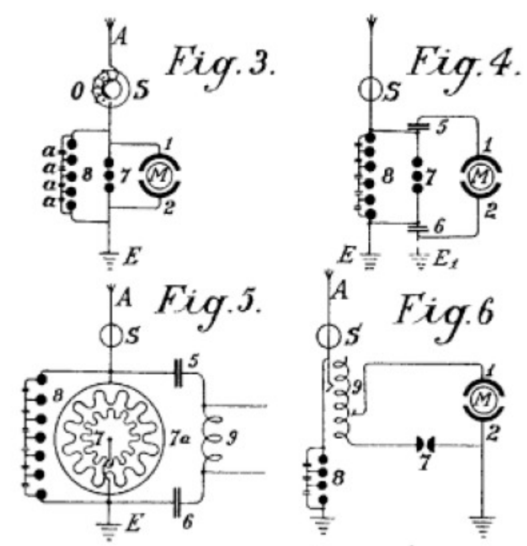

Figure 3 shows the simplest way of converting atmospheric electricity into electromagnetic waves. Recent improvements in motorsport with motorsports, work States

Diagrammatically indicated by the two semicircles 1 and 2 and the rotor of the motor by a ring M (Figure 3). A is a vertical aerial or aerial network. The electr electromagnet and the electromagnet with the spark gap, the circuit 8 with the spark gap , and then a circuit including the stator terminal 1, the rotor and st which the connection is made to the earth wire. The two spark gaps are also connected metallically with the earth wire. These methods are as follows:

The positive atmospheric electric charge collected with the earth. It goes through the electromagnet. Further, its progress is arrested by two sparks gaps place the stator condenser surfaces. The stator condenser surfaces are charged until the charge is higher than the resistance of the spark gap 7, whereupon a spark spark gap 7, and an oscillatory charge is obtained from the motor M, stator surfaces 1 and 2, and spark gap 7, a closed oscillation circuit is obtained electromagnetic oscillations. The motor here forms the capacity and the necessary inductance and resistance, which, as is well known,

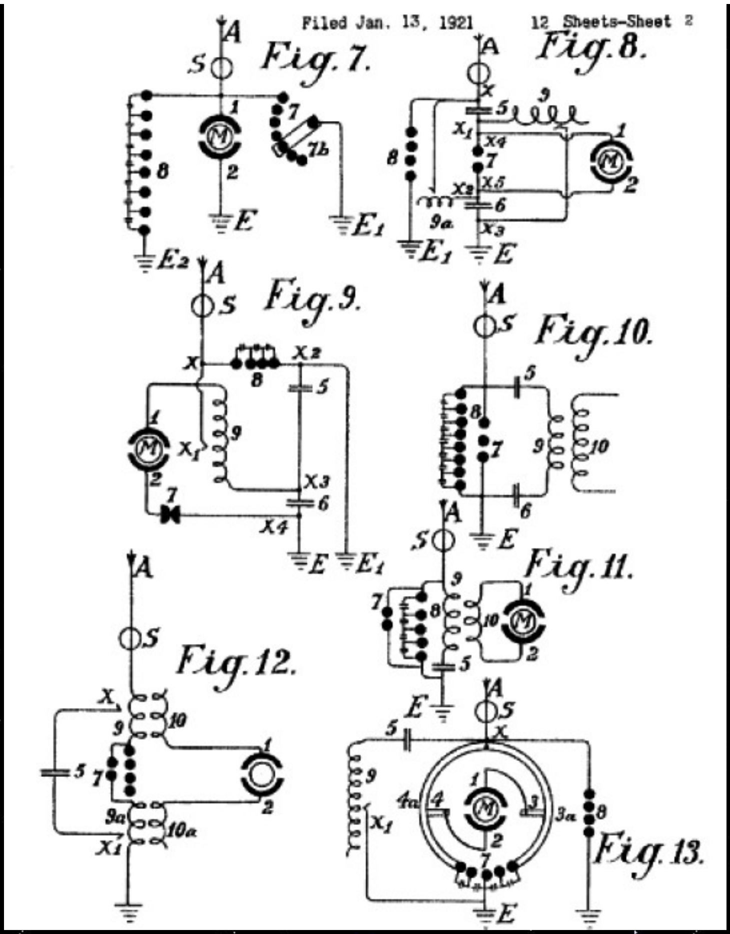
By the electromagnet or choke. A light source, a periodic difference in the electromagnet, a periodic difference between the two, and is. This is the case of the which is sufficiently high, and is supplied to the flow of atmospheric electricity.

With the wave of the motor, it does not end with the natural frequency of the motor, it does not endanger the motor through the spark gap.

In the diagram illustrated in Figure 4 the spark gap is shunted across condensers 5 and 6 from the motor.

In Figure 5 a diagram is illustrated for large current strengths which may be direct direct without motors, for example, for lighting or heating purposes. The r that the spark gap consists of 7 When separated from one another, discharges take place, thus forming an oscillation circuit over condensers 5 and 6, and oscillatory discharges. It is evident that a motor may be connected to the ends of the spiral 9.

The construction of the diagram is shown in Figure 6 of the oscillating circuit of the motor being connected with an induction coil. Motorcycles can be more or coiled 9 (coupled inductively to the aerial).



In Figure 7 the oscillation circuit is closed through the earth (E and E1). Spark gap 7 may be prolonged or shortened by more or fewer spark gaps being succe by means of a contact arm 7b.

Diagram 8 shows a unipolar connection of the motor with the aerial network. Here two oscillation circuits are closed through the same motor. Electroma inductance 9a to the earth condenser 6 and further, over spark gap 7 to the aerial condenser 5 and back to *x* . The second oscillation circuit from the aerial c point x^{1} over the inductance 9 to the earth condenser 6 at the point x^{3} and through the condenser 6 over the spark gap 7 back to x^{1}. The motor itself is ins two points of the spark gap 7. From this arrangement, slightly damped oscillation wave currents are produced.

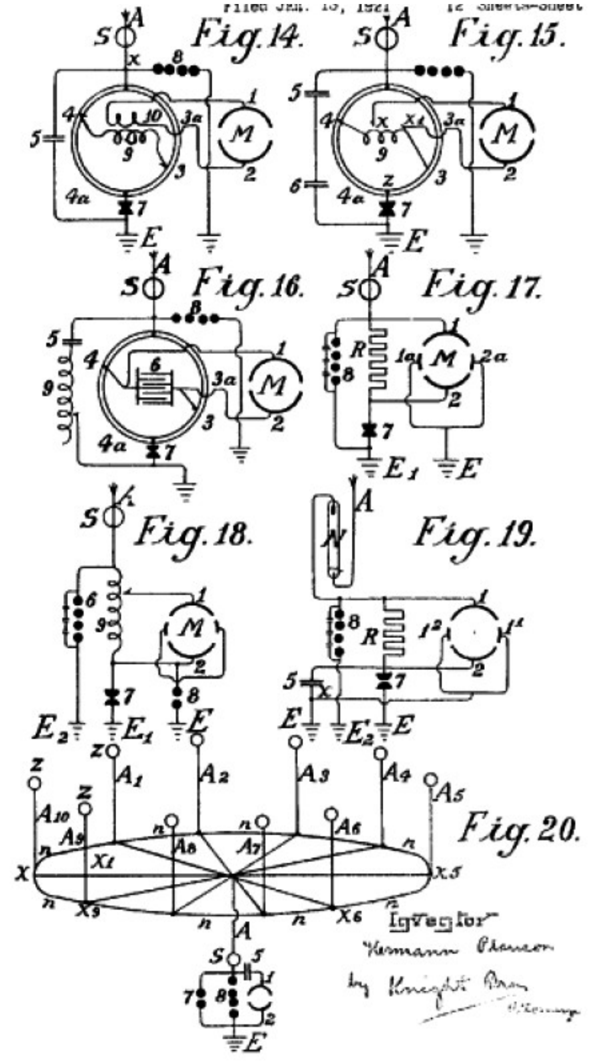
In the diagram illustrated in Figure 9, a loosely coupled system of connections is shown as being for small motors for measuring purposes. A the aerial electromagnet in the aerial conductor, 9 the inductance, 7 the spark gap, 5 and 6 condensers, E the earth, M the motor, and 1 and 2 stator connections of the mo directly metallically connected with the oscillation circuit.

In Figure 10 a purely inductive coupling is employed for the motor circuit. The motor is connected with the secondary wire 10 as may be seen in Figure modified diagram connection. Figure 12.

The diagrams are hitherto described as preferable of motors of small and medium strength to be operated. For large quantities of energy is difficult; swit greater.

A means of overcoming such difficulties is shown in Figure 13. The oscillation circuit starts from the point x over condenser 5, variable inductance 9, spark g segments (3rd and 4th) forming arms of a Wheatstone bridge, electromagnetic oscillations of equal and electromagnetic oscillations are shown in the c approximate. If the the brushes 3 and 4 are moved in common with the conducting wires 1 and 2 which connect the brushes with the stator poles to ce displacement of the polarity is obtained and the motor commences to revolve.

The maximum action will result if one brush 3 comes on the central sparking contact 7 and the other brush 4 on the part *x* . Gaps with the motor oscillation circ



14. The diagram 14 differs from the foregoing only by the motor not being directly related to the motor commutator, but only a primary coil 9 which induces i
10, current which feeds the motor M and takes the place of the rotor. A loose coupling and an oscillation circuit without a spark gap.

In Figure 15 the motor is not purely inductive as in 14, but directly metallically branched off from the primary coil (at x and x^1) after the principle of the auto-

In Figure 16 instead of an inductance condenser 6 is similarly, and for the same object inserted between the segments 3a and 4a. This has the advantage that t
need to be made of solid metal but may consist of spiral coils whereby a more exact regulation is possible and further motors of high inductance may be employ

The arrangements of Figures 17, 18 and 19 may be employed for use with resonance and particularly with induction condenser motors; between the larg
condenser surfaces, small reversing pole condenser surfaces, mall reversing pole condensers are connected, which can be seen from Figures 17, 18 and 19 a
earth. Such reversing poles

Figure 19 shows a method of electromagnetic oscillations of the high number of alternations. It is based on the well-known principle of a mercury lamp, one e
is formed of mercury, the other of solid metal. . The mercury electrode of the vacuum tube. From this it can be only from the aerial through the vacuum tube
circuit, but not vice versa. Oscillations which are formed on being transformed into an oscillating circuit.

In practice these vacuum tubes must be connected behind the danger of lightning.

As regards the use of spark gaps, can be used for wireless telegraphy may be used. Of course the spark gaps in large machines must have sufficiently large
cooled in liquid carbonic acid or better still in liquid nitrogen or hydrogen; in most cases the cooling of the metal series by the means of hydrocarbons the
which lies between -90 ° C and -40 ° C. The spark gap casing must also be insulated and may be strength to be able to resist any pressure which may arise.
excess super-pressure which may be formed must be automatically let off. Mercury electrodes which were frozen in liquid carbonic acid,

Figure 20 is one of the simplest forms of construction of an aerial network in combination with collectors, transformers and the like illustrated diagrammatic
earth wire, 8 the spark spark gap, 7 the working spark gap, 1 and 2 the stator surfaces of the motor, 5 to the condenser battery, the protective magnet which is
coil in aerial conductor, A^1 to ^{10} aerial antennae with collecting balloons, horizontal collecting or connecting wire from which, to the center to number of conn

The actual collectors consist of metal sheaths, preferably made of aluminum magnesium alloy, and are filled with hydrogen or helium and are attached to c
wires. Is the actual weight of the balloon and the weight of the conducting wire. On top of the balloon aluminum spikes, made and gilded in a special m
described, are arranged in order to produce a conductor action. Small quantities of radium preparations, more particularly polonium-ionium or meso-thor
considerably increase the ionization, and therewith the action of these collectors.

In addition to metal balloons, fabric balloons which are superficially metal coated according to Schoop's metal spraying process, may also be employed. Th
may also be produced by lacquering with metallic bronze powders in two electrical series of widely different metals.

Instead of the ordinary round balloons, they can be used. Non-conducting substances, which produces electricity by the wind, also produces electricity collecting effect is substantially increased, the wind will impart a portion of its energy in the form of frictional electricity.

In practice however, very high towers may be used as an antenna. In these towers, copper tubes freely rise above the top of the tower. Lamp to form a col conveyed through the interior of the tube up to the summit. The copper tube must be protected from the effects of the tower and the rain must be prevented by walls of the tower. This is done by a series of enlargements of the Siamese pagodas.

Special attention must be devoted to the foundations of such towers. They can be well insulated from the ground, which may be obtained by first embedding a in a box. . There is an iron-concrete layer in which the metal foot of the tube is secured. This concrete block must be at least 2 meters from the ground. In the tower a wood or glass house for the large condenser batteries or for the motors may be constructed. In order to lead the earth to a well-insulated pit constructed must be provided. These towers are erected at equal distances. To be used on high voltage conductors. Can be taken at any suitable places.

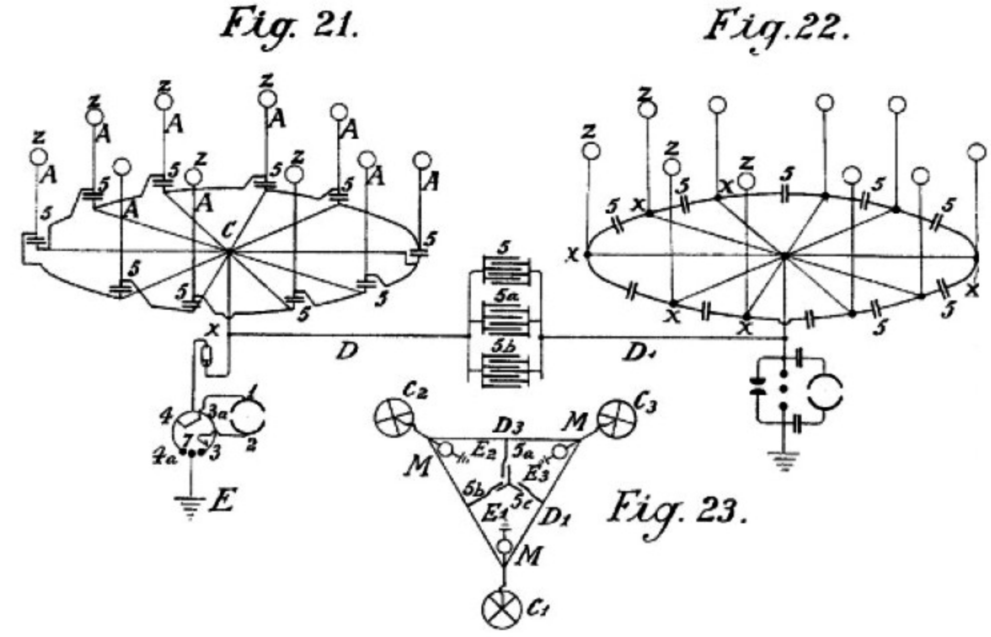


Fig. 21.

Fig. 22.

Fig. 23.

In order to collect a large number of units of electricity, please refer to Figures 21 and 22. In Figure 21 the batteries of condensers Z by the aerial conductor, t the other conductor.

Figure 22 shows a similar arrangement, or two different series of antennae rings for sufficiently large capacitor batteries (5, 5a, 5b) by means of Maji star cond In Figure 23 a connection of three such rings with a central condenser battery is illustrated.

The condenser batteries of such large installations must be embedded in liquid gases or liquids freezing at very low temperatures. In these cases a portion o energy must be used for liquefying these gases. It is also preferable to employ pressure. This is the reason why this is not the case. For smaller installations the condensers in well-insulated oil or the like, suffices. Solid substances on the other hand can not be used as insulators.

The arrangement in the diagrams was shown to be such that the condenser batteries were connected with both poles directly to the aerial condensers. An imp the connections for the supply of electricity to the condenser batteries has been found to be very advantageous. This arrangement consists of one pole (unipolar network. Such a method of arrangement is very important, as a means of being a constant current and an increase of the normal working pressure or voltage i have a collecting balloon, which is allowed to rise to a height of 300 meters, shows 40,000 volts above earth voltage, in practice it is only about 400 volts. Bal of the condenser, the capacity of the condenser surfaces up to and beyond 500 volts. This can be ascribed to the favorable action of the connecting method. t aircraft in the air with the exception of 500 volts. . This can be ascribed to the favorable action of the connecting method. the capacity of the aircraft in the air of 500 volts. . This can be ascribed to the favorable action of the connecting method.

In addition to this substantial improvement, it has also been found to be a double inductance with electromagnets. It can also be used as an induction coil or as or as a condenser itself as an induction condenser. This is a condenser that can be applied to the accumulated force. Condenser pole, and if the spark gap is accumulated energy is again given back to the free condenser pole. The same as the collector network. Increased energy. Inserted in the same space of time.

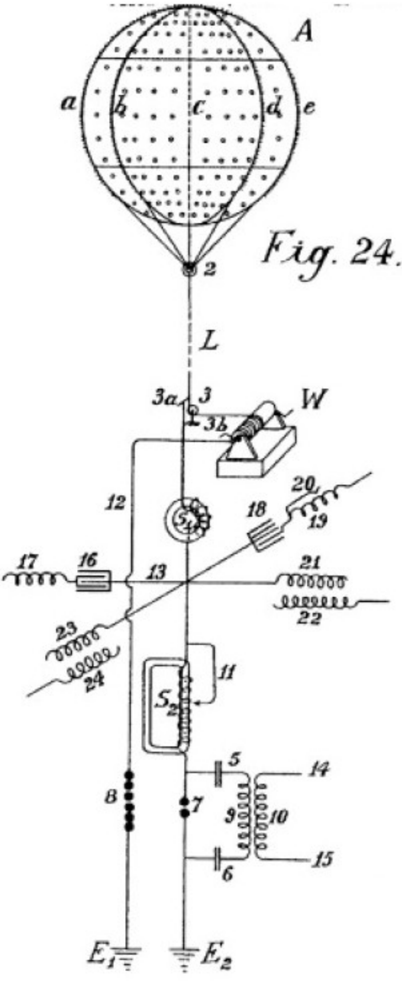

Fig. 24.

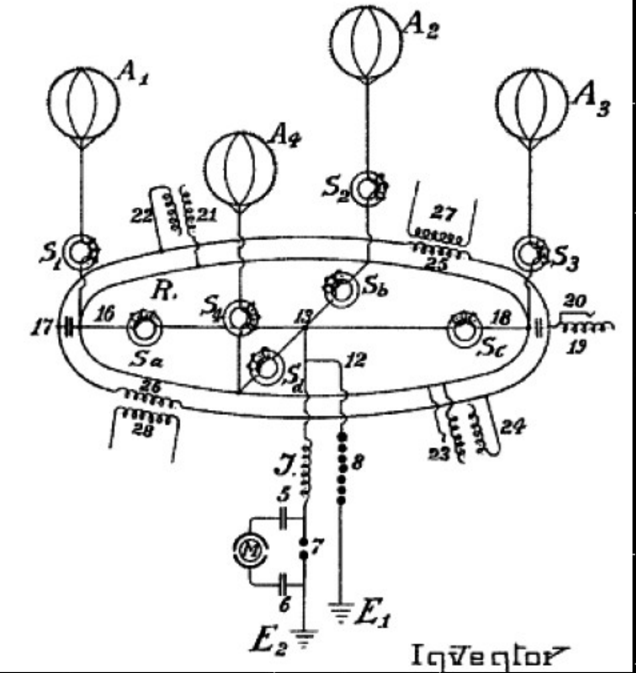

Fig. 25.

In Figures 24 and 25 two different diagrams of connections are shown, Figure 24 shows a collecting balloon and the diagram of the connections to earth. Figu collecting balloons and the parallel connection of the condenser batteries belonging thereto.

A is the collecting balloon made of an aluminum magnesium alloy (electron metal, magnalium) of a specific gravity of 1.8 and a thickness of plate 0.1 to 0.2 are eight strong vertical ribs of T-shaped section about 10 to 20 mm in height and about 3 mm in thickness with the projecting part directed inwards (indicated so forth); They are riveted together to form a skeleton and are stiffened in a horizontal direction by two cross ribs. Internally and transversely by means o whereby the balloon obtains great power of resistance and elasticity. Rolled plates of 0.1 to 0. 2 mm in thickness made of magnalium alloy are then either sold this skeleton coppered steel hawser L twisted out of separate thin wires (shown in dotted lines in Figure 24) and which should be long enough to allow the bal desired height, to metal roller or pulley 3 and from thence to a winch W, well insulated from the earth. The means of this winch, the balloon, which is filled helium, and brought to the ground for recharging or repairs. the coppered steel hawser The twisted out of separate thin wires (shown in dotted lines in Figu should be long enough to allow the balloon to rise in the desired height, to metal roller or pulley 3 and from thence to a winch W, well insulated from the ea this winch, the balloon, which is filled with hydrogen, or helium, and brought to the ground for recharging or repairs. the coppered steel hawser The twisted o wires (shown in dotted lines in Figure 24) and which should be long enough to allow the balloon to rise in the desired height, to metal roller or pulley 3 and winch W, well insulated from the earth. The means of this winch, the balloon, which is filled with hydrogen, or helium, and brought to the ground for rechargin

The actual current is taken directly through a friction contact from the metal 3 or from the wire, or even from the winch or from the three by means of brush

Beyond the brushes the conductor is divided, the paths being: --- firstly over 12 to the safety spark gap 8, from the earth to the conductor E^1, and secondly o S^1, point 13, to a second loose electromagnet having an adjustable coil S^2, then to the spark gap 7 and to the second earth conductor E^2. The actual working through the spark gap 7, condensers 5 and 6, and through the primary coil 9; here the static electricity formed by oscillatory discharges is accumulated and co

frequency electromagnetic oscillations. Between the electromagnets S^1 and S^2 at the crossing point 13, four condenser batteries are introduced diagrammatically in the drawings each by one condenser. Two of these batteries (16 and 18) are induction condensers and prolonged by regulating induction and 19 while the two others (21 and 23) are induction condensers. The condenser batteries 16, 18, 21 and 23 are connected by only one pole to the aerial conductor. The second poles 17, 19, 22 and 24 are open. In the case of plate condensers having no inductive resistance and an induction coil is inserted. Th spiral or coil is the displacement of the current phase by 1/4 periods, while that of the current charge of the condenser poles which lie free in the air, works bac aerial. The consequence of this is that in the aerial collectibles. It has also been found in The length of the coil in the size of the induction coil. It has also b length of the coil in the size of the induction coil. It has also been found in The length of the coil in the size of the induction coil.

S^1 and S^2 may be provided with such regulating devices in the case of S^2 (illustrated by 11). 12 and spark gap 8 or through any other suitable apparatus, si would be dangerous for the other apparatus.

The small circles on the collector balloon indicate places at which zinc amalgam or gold amalgam or other photoelectric acting metals in the form of small pat thin layers (0.01 to 0.05 mm in thickness) are applied to the entire balloon as well as in greater thickness to the conducting network. The capacity of the c increase strengthened at the surface. Polonium amalgams and the like. On the surface of the collector balloon metal points or spikes are also fixed along the serve for collecting the collector charge. For this purpose it is very important to employ as sharp spikes as possible. Spikes made of bars or rollers with a large spikes made of bars or rollers with rough surfaces. Here you are experimented with the collector balloons hereinbefore mentions. The best results were give were made in the following way. End points made of steel, copper, nickel, or copper and nickel alloys, were fastened together in bundles and then placed points in a suitable electrolyte (preferably in hydrochloric acid or iron) at 2 to 3 volts pressure. Spikes or pins the points become extremely sharp and the bo have a rough surface. The bundle can be washed off with water. Platinum, iridium, palladium or wolfram salts or their compounds and coated with a cathode w precious metal, which must be sufficiently firm to protect them from atmospheric oxidation.

Such spikes act at a 20-fold lower voltage almost as well as the best and finest points made by mechanical means. Polonium or radium salts are added to the g forming and protective layer or coating. These pins have a low resistance at their points.

In Figure 24 the three unconnected poles are not connected with one another in parallel. That is quite possible in practice without altering the principle of the f preferable to interconnect in parallel to a common collector network, a series of collecting aerials.

Figure 25 shows a diagram for such an installation. A^1, A^2, A^3, A^4 are four metal collector balloons with gold or platinum coated spikes which are electr the presence of polonium emanations or radium salts, which spikes or needles are connected over four electromagnets S^1, S^2, S^3, S^4, through an annular c this annular conductor four wires run over four further electromagnets Sa, Sb, Sc, Sd, to the connecting point 13. the safety spark gap 8 to the earth at E^1, inductive resistance J and the working spark gap 7 to the earth at E^2. The working circuit, consisting of the condenser 5 and 6 and a resonance motor herebefore described, is connected in proximity with the sparking gap section 7.

Of the primary circuit for high frequency oscillatory current may also be connected.

The condenser batteries are connected by one and the inductionless (16 and 18) or made as induction condensers as shown by 21 and 23. The free poles condensers are indicated by 17 and 19, those of the induction condensers by 22 and 24. May be interconnected in parallel through a second annular conductor that the principle of the free pole connection will be injured. In addition to the advantages already set up the parallel connection also provides an equalizati pressure. Suitable constructed and calculated induction coils 25 and 26 may also be included in the annular conductor of the free poles,

According to what has been hereinbefore stated separate collector balloons may be connected to equidistant stations distributed over the entire country, or c with one other metallically or by means of intermediate suitably connected capacitor batteries through high voltage conductors insulated from earth. This i following criteria: The wires leading from the collector balloons have hitherto been connected through an annular conductor without this endless connection, b any action on the whole conductor system.

A condenser, or short circuited in the form of coils over a condenser battery or spark gap or through thermionic tubes or valves or audions, then the total c exhibits quite new properties. The collection of atmospheric electricity is not only available in the collector network. Further, the atmospheric electrica themselves in the higher regions. In Figures 26 and 28 a form of construction is shown on the basis of which the further foundations of the method will be parti

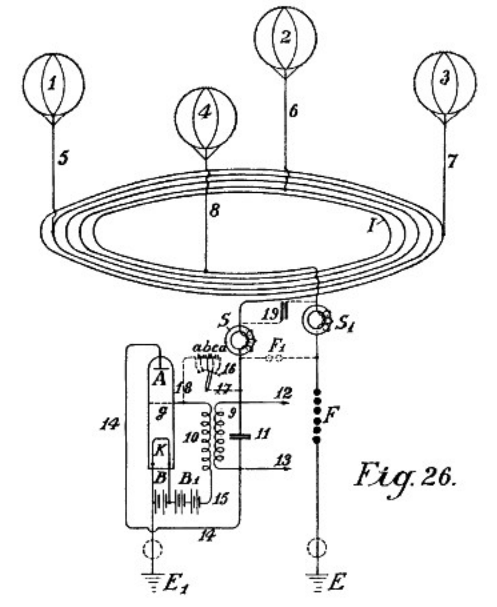

Fig. 26.

In Figure 26, 1, 2, 3, 4 are metal collector balloons, 5, 6, 7, 8 their metallic aerial conductors and the actual collector network. High voltage masts in high v coil has a diameter of 1 or 100 km or more. S and S^1 are two protective electromagnets, F the second safety section against excess voltage, and its earth con earth conductor of the working section. Anion of the electromagnet S, primary induction coil 9, conductor 14, anode tube, incandescent cathode K, as electromagnet and the safety spark gap F offers considerably greater resistance. An electromagnetic alternating field is produced in the interior of the colle whereby the whole free electrons are directed into the interior of the coil. An increased ionization of the atmosphere. In addition to this, they will be show balloon show a reduced reduced resistance and therefore increased static charges between the points on the balloon and the surrounding atmosphere are pro this is a significantly increased collector effect.

A second effect, which can not be obtained from the electromagnetic alternating field, which runs parallel to the earth surface, whereby in the case of fluctuati a return induction current of reversed signal is always produced in the collector coil by earth magnetism. Now if the current periodicity is also produced network coil. As the same alternating field is further transmitted to the aerial balloon, while the collector action is considerably increased. A further advantage i of potential of the collector area. The field of collectable surfaces, when the collateral surfaces occur, when the collectable surface is produced by the law induction of reversed sign on the collector surface and so on charge). In addition to the advantages hereinbefore set, the construction of connecting conductor when sufficiently large, also in the simplest way. Sturmo's fire or northern lights. These energy quantities have not been available to be used up to now. By these kinds of energy, as they are of an electromagnetic nature and the direction of the axis of the collector coils stands at the right angles to the earth's surfac less absorbed in the same way as a receiver in a wireless telegraphy absorbs waves coming from to distance. It is possible to connect large surface and to take u of energy. can be more or less absorbed in the same way as a receiver in a wireless telegraphy absorbs waves coming from a far distance. It is possible to con and to take up large quantities of energy. can be more or less absorbed in the same way as a receiver in a wireless telegraphy absorbs waves coming from a possible to connect large surface and to take up large quantities of energy.

It is well known that it is large diameter. If it is constantly taking place in the atmosphere. Particularly in the tropics or still better in the polar regions where t are present, large quantities of energy may be obtained in this way. A coil with several windings should act the best. In similar manner, any alteration of the should act inductively on such a coil.

This is an induction in that collector coils of sufficient size. In the same way, this collector will react on the earth. By combining the previous kind of current form of electricity are considerably increased.

In order to produce the improved collector coil, a uniform current oscillations of an undamped nature may be called a "high vacuum or thermionic tubes of sui

instead of the previously known spark gaps (Figures 26, Nos. 9-18). Electromagnet The main aerial current flows through electromagnet ($^{1)}$) and may be c primary coils in the induction winding through wire. Parallel with the induction resistance 9 a regulating capacity of a suitable size, such as condenser 11 lower part of the tube, the tube is arranged for the incandescent filament or the cathode K which is fed through a battery B. From the battery B two branches ru

conductor E^1 and the other through battery B^1 and secondary coil 10 to the grid above *g* in the vacuum tube. By the method of connections shown in dotte

voltage at the grid electrode *g*may also be produced through the wire 17 and some small capacitors (*a, b, c, d*) connected in series, and conductor 18, witho being required.

The action of the entire system is somewhat as follows: -

The condenser pole 11 is charged and slightly damped oscillations are formed in the short circuited existing oscillation circuit of the condenser 11 and self ir fluctuations of the voltage in the anode circuit, with the same frequency, which changes the strength of the electrode . A permanent supply of energy to the osc and 10 consequently takes place, until a condition of balance is set up, in which the consumed oscillation is equal to that absorbed.

For a period of 180 ° so that if the grid is negatively charged, then the anode is positively charged and vice versa . This is the possibility of separating the osci the connection between the anodes and the grid circuit and so forth.

A second important factor in this way of converting the use of the grid circuit, or as shown by dotted lines 16, 17, 18 by means of a larger or smaller numbe

suitable size connected in series ; in this case the battery B^1 may be omitted. With a suitable selection of the grid potential in glow discharge takes place betw the anode A and a dark space is formed. The size of this cathode is influenced by the ions which are emitted in the lower space. On the other hand the numb through the grid is dependent on the grid between the grid and the cathode. Thus is the grid voltage undergoes periodic fluctuations (in the present case) t cathode drop at the grid fluctuates and consequently the internal resistance of the tube correspondingly fluctuates, so that takes place, the necessary means ar production of undamped oscillations and of taking current,

The frequency of the undamped oscillations produced with the coupling of the oscillation circuits 9 and 10. By a suitable selection of the self induction of th electromagnetic oscillation of only a few meters wavelength down to the lowest High vacuum transmission tubes of 0.5 to 2 kw in size can be connected in para

Dynamics circuit is also known to be used as such tubes for producing undamped oscillations, and also on the contrary their use at lower voltages is considerab Gaps must be considered as an ideal solution for the use of high-voltage electricity.

By the application of safety spark gaps, with interpolation of electromagnets, not only is short-circuating but also the taking up of current is regulated. Osc inserted in the above way form a constantly acting electromagnetic alternating field in the collector coil, whereby accumulated effect takes place. electromagnetic alternating field, so long as the direction of its axis running parallel with that of the main current.

In oscillation circuits 9 and 11, electromagnets S and S^1 must be inserted if the high frequency oscillations are not to be penetrated the collector oil, betwe producers and the collector coil. In all other cases they are connected shortly before the earthing (as in Figures 27 and 28).

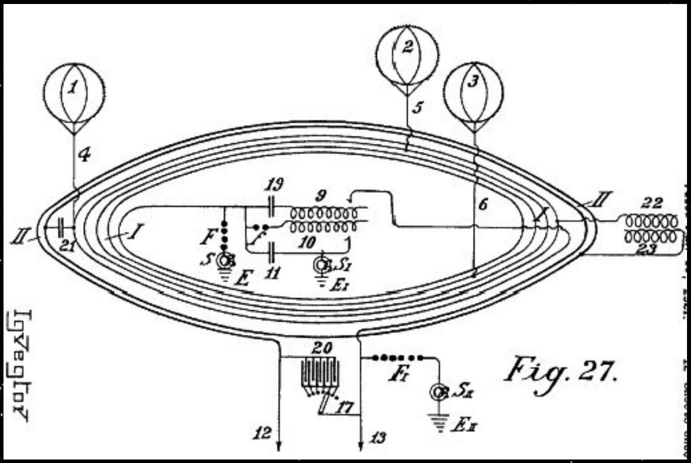

Fig. 27.

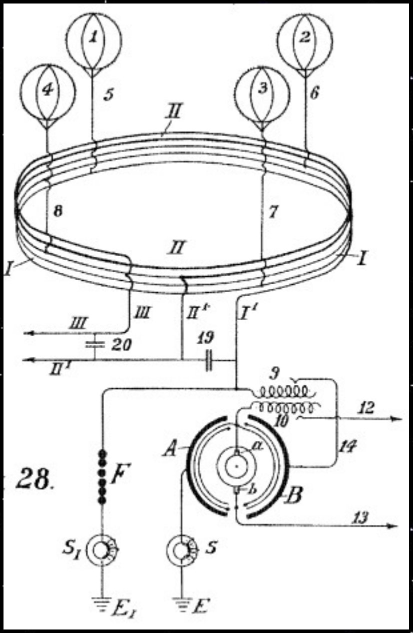
In Figure 27 a second method of construction of the connecting conductor is shown in the form of a coil. The other annular conductor II is inserted parallel to t the air but both in the form of a coil. The connection of the balloon aerials is indicated as a primary conductor and also as a current producing network; the ot and is not connected to the current production network.

In Figure 27, the current producing network is shown with three balloon collectors 1, 2, 3 and aerial conductors 4, 5, 6; it is short-circuited through condenser

9. The oscillation forming circuit consists of this diagram of spark gap f, inductance 10, and condenser 11; the earth wire E 1 is connected to earth over elect the spark spark gap which is also connected to earth through a second electromagnet S at E. On connecting the condenser circuit. This discharging cur inductance 10 on the inductively coupled secondary 9, whereby in the producing network a modification of the potential of the condenser 19 is produced. producer network. These oscillations induces a current in the secondary circuit, which corresponds to the proportion of the number of windings and of the oh greater.

In order to be able to convert the current wavelengths, a sufficiently large regulatable capacity of 20 into inserted between the ends 12 and 13 of the secondary and to be connected to the earth over an electromagnet S2.

The over-induction condenser 21 or over an induction condenser 22, 23. In this case the secondary conductor is unipolarly connected with the energy conducto



28.

In Figure 28, the connecting conductor between the separate accumulator balloons is carried out according to the autotransformer principle. The collecting c aerial balloons 1, 2, 3, 4, the windings of which are not made side by side but one above the other. In Figure 28 the collector coil I is shown with a thin lin connected prolongation coils II with a thick line. Between the ends I^{1} and II^{1} of the energy networks in the regulating capacity 19 is inserted. The wire ^{1} is c wire output and the spark gap F.

As a transformer of the electricity supply, it is made of rotary pairs of condensers in which the one is connected to the earth pole. Collector rings and brushes, alternating current, the frequency of which is dependent on the number of balloons and the revolutions of the rotor. In this invention, in this improved method this invention, through coils 1 on the inductance 9, an increase or decrease of the current feed in I can be obtained according to the direction of the current by ba

These rhythms produce short-circuited through the regulatable condenser 19 these rhythms produce short-circuited undamped oscillations in the energ periodicity and wave wavelength and therewith also to a given frequency. These currents may Also be employed in this form directly as working current throu II^{1} and III. By inserting the condenser 20 a connection between these conductors may also be made, whereby harmonic oscillations of desired wavelengths ar means quite new effects as regards current distribution: Coil with a cable or a cable to a point in the interior of the producing network is firmly or movably mo conductor. In this case it is induced in the producing network, the size of which is dependent on the total capacity and resistance and also on the periodi potential or afford afforded in the future, network by wireless means. This is also the case for the acquisition of energy for the future.

Instead of spark gaps grid vacuum tubes may be used as producers for undamped oscillations. The separated coils of the producer may be connected with on separate conductors all in parallel or in series or in groups in series. By collulating the number of oscillations and also the extent of the voltage more or less T be spirally over the entire section. Angular form or also in triangular, quadrangular, hexagonal or octagonal form.

The current waves as guides. This is necessary when the currents have been taken over mountains and valley and so forth. In all these cases, the current must b current of suitable periodicity.

As already hereinbefore mentioned separate collecting balloons may be directly metallically interconnected at equidistant stations distributed over the entire c connected by interpolation of suitable capacitors. A range of oscillations, and could be in such forms, a wit to a suitable arrangement of the connections, measures of protection, regulation.

Collecting effect of the balloon in the aerial collector of the balloon, radiating collectors are employed. These consist either of incandescent metal or oxide elect of vacuum tubes, or electric arcs (mercury and the like electrodes), Nernst lamps, or finally flames of various kinds may be connected with the respective condu

An incandescent body with an incandescent body and an electric tube. Hitherto however, a cathode was always first directly placed as an anode, and secondly t consisted of a closed circuit.

Light and flame arcs in which a cathode only as a source unipolar discharge (which represent group and point discharges in electrostatic machines si discharges), it may be ascertained that incandescent cathodes and less all incandescent radiators, flames and the like radiate into the open space in the form o as transmitters.

The object of this invention is as described below, if such incandescent oxide electrodes or other incandescent radiators or flames are not supported in spa metallically with the earth so that they can be charged with negative terrestrial electricity, these radiators possess the property of absorbing the free positive e They can serve as collectors and have, in comparison to the action of the spikes, or points, a very large radius of action R; the effective capacity of these c greater than the geometrical capacity (R$_{or-}$) calculated in an electrostatic sense.

Now as our earth is surrounded by an electrostatic field and the difference of potential

$$\frac{\delta V}{\delta h}$$

of the earth field according to the latest investigations, is in the summer about 60 to 100 volts and in the winter 300 to 500 volts per meter of difference in heig calculation gives the result that when a radiation collector or flame collector is arranged for example on the ground, with a distance of 2000 meters and both a conducting cable, there is a difference in potential in the summer of about 2,000,000 volts and in winter even of 6,000,000 volts and more.

According to Stefan Boltzmann's law of radiation, the quantity of energy, which is an incandescent surface (temperature T) of 1 sq cm, radiates into a unit of t air (temperature T_o) is expressed by the following formula:

$S = \delta(T^4 - T_o^4)$ watt./sq cm.

Equal to 6.30 x 10^{-12} watt / sq. Cm. And the universal radiation δ is based on the latest researches of Ferry (*Annales de Chimie et de Physique* , 17: 267 [1909

Now if an in incandescent surface of 1 sq cm shows, as Compared with the surrounding space a periodic fall of potential δV it radiates (independent of the That is to say of the sign) secondo with the above formula, for example at a temperature of 3725 ° C an energy of 1.6 kw / sq cm / second. As for the radiatio can be calculated for the collection of energy, but reversed. 60 cm to 65 cm per cm per cm, no carbon will result in this direction in employing radia accumulators.

If the earth be regarded as a cosmically insulated condenser in the sense of geometrical electrostatics *x* there results from the geometric (appears Edwald Rasch *Bogenlicht* [The Electric Arc Light], page 169) capacity of the earth according to Functional Chwolson:

For negative charging 1.3 x 10^6 Coulomb

For negative potential V = 10 x 10^8 volts.

From this there results however, EJT = 24.7 x 10^{24} watts / sec. This is an example of an electrician, who works for about 79,500 x 10^{10} kilowatt years. thermodynamically, electromagnetically and also kinematically coupled with the sun and a system of cosmic radiation and gravitation. The energies Which collectors would withdraw from the earth field can only houses by the withdrawal of motor work in lowering of the earth temperatures (temperatures T_E = 30

to the world of space (T = O) by using the entire energy. This is not a cosmically entirely insulated system. From the sun an energy of 18,500 x 10^{10} kw. lowering of the earth temperature (T_E) without a simultaneous lowering of the sun's temperature (T_s) would contradict Stefan Boltzmann's law of radiation.

$S = \delta(s^4 - T^4)$.

From this it must be Concluded That if the earth temperature (T_E) sinks the total radiation S absorbed by the earth Increases, and Further Also That the secula of the earth is directly dependent on That of the sun and the other radiators cosmically coupled with the sun and is connected with most closely.

The incandescent radiation collectors may be used for negative energy and if they are (1) are charged with the negative earth electricity and (2) if large surfaces) charged with electricity are mounted opposite them as positive poles in the air. It is not possible to collect with an incandescent collector, sufficiently the electrical charges contained in the atmosphere as the technology requires; very small, especially if it be considered that the very small surface density (e about = 2 x 7. 10^9 St. E. per sq cm) does not allow large quantities of charge being absorbed from the atmosphere.

x) Calculated according to Poisson's calculation:

$\Delta V = -4\pi\delta$; as here the alteration of the potential or potential is taken place in the direction or the normal, this calculation assumes the simple form

$$\delta = \frac{1}{4\pi} \times \frac{\delta^2 V}{\delta n^2}$$

It has been already proposed to be used as collaterals for collectibles. It is however, not known that the quantities of current which could be hitherto be s purposes. According to my experiments the reason for this is too small capacities of the collector conductor poles. If such flame or radiating collectors have positive surfaces, their radius of action is too small. If the incandescent collectors are being held in practice, they are not yet being carried out in practice.

By this invention the collector effect is considerably increased by a positive potential and the possibility of being held floating in the air at a desired height. A of sheet metal or of metalized balloon made to mount to 300 meters to 3000 meters in the air and as a positive pole it is brought forward to a radiating collect conductor to the earth, quite different results are obtained.

The metallic balloon shell (with a large surface) This is the greater the collecting balloon is above the incandescent collector. It is being attracted through th ionization, proceeding from the incandescent cathode. Collection of the incandescent cathode collector is appreciatively enhanced and also the collection balloon surface. More than a large piece of water, if it is not enough .

In the air and being in the air in the air conductively connected to earth.

Condenser and an inductive resistance being switched on in parallel, a process that can be carried out by two such contacts.

Such as radiating collectors in series. An incandescent cathode may be seen from the open ground and an incandescent cathode which is heated by specia currents. Of course for this the special vacuum Liebig tubes wit or without grids may also be employed. An ordinary arc lamp with oxide electrodes may be ground and the positive pole is not directly connected to the collecting balloon, but through the upper inc. The method of connecting the incandescent cathode may be seen in Figures 29-33.

B is the air balloon, K a Cardan ring (connection with the hawser), C the balloon, L a good connecting cable, P a positive pole, N negative incandescent cat conductor.

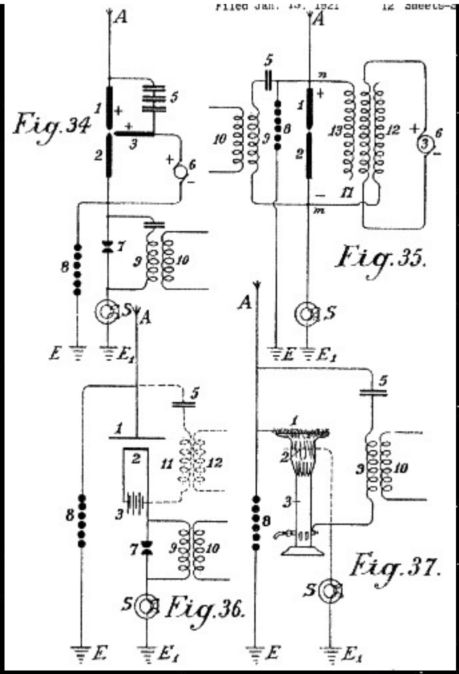
In this form of construction, both the incandescent cathode and the positive electrode may be enclosed in Figure 32. A cable is insulated in a condenser dis arched in order to keep off the rain. The vessel is completely made of magnetic metal and well insulated inside and outside. Opposite the disc 5 another disc 6 a positive pile of the vacuum tube with the incandescent cathode (oxide electrode) N is arranged. The negative electrode is being connected to the earth. Figur of an open incandescent cathode one enclosed in vacuo is employed. As in such collectors only small bodies can be brought to incandescence in large installatio such vacuum tubes must be inserted in proximity to one another. According to the previous constructions Figures 31 and 33 are quite self evident without furthe



Figures 34-37 represent further diagrams of connections over radiating and flame collectors, and in fact, they are to be arranged on the ground.

Figure 34 shows an arc light collector with oxide electrodes for direct current and its connection; Figures 35 a similar one for a current flame, Figure 36 a simi flame.

The positive pole 1 of the radiating collectors is always directly connected to the aerial collecting conductor A. In Figure 34 this is connected Further over the 5 with a second positive electrode 3. The direct current dynamo *b* Produces Which current flows over between the electrodes 3 and 2 as an arc light. The neg electron 2 absorbs electricity from the positive poles The spark gap 7, inductive resistance 9 and induction coil 10 are like the ones previously describe electromagnet S the guard against the circuitry, the safety spark gap 8 from excess voltage or overcharging.

In Figure 35 the connection is so far that the alternating current dynamo feeds the exciting coil 11 of the induction condenser. 12 is its negative and 13 its po coil 3 on the magnet of the dynamo is correctly calculated and the periodicity of the alternating current is sufficiently high and can be formed between the two the cathode 2 is connected with the negatively charged earth, and therefore always acts as a negative pole, a form of rectification of the alternating current dynamo 3 is obtained, the second half of the period is always suppressed. The working circuit may be carried out in the same way as in Figure 34; the wo however be dispensed with,

Figures 36 represent a form of construction similar to the figure of an arc lamp in Nernst incandescent body is employed. The Nernst lamp is fed through t working section is connected with the negative pole. It is also available for 12 over the oscillation circuit 5, 11 (shown in dotted lines).

Flame collectors (Figure 37) may also be employed according to this invention. The wire network 1 is connected to the aerial collector conductor A and th earth. At the upper end of the dairy, long points are provided which project into the flame. The positive electrode is connected with the negative over a co induction coil 9 with the earth.

The novelty in this invention is firstly, the use of the incandescent cathodes opposite the positive poles which are connected with the large metallic capac collecting surfaces, (2) the connection of the incandescent cathodes with the earth whereby, in addition to the electricity conveyed to them from the battery c causes the incandescing, and (3) the connection of the positive and negative poles of the radiating collectors over a condenser circuit alone or with the introdu inductive resistance, whereby an oscillatory oscillation circuit may be obtained. The collecting effect is from these methods quite considerably increased.

(10 July 1922)

Improvements in Electric Motors

Hermann Plauson // Otto Traun's Forchungs-Laboratorium GmbH

This invention relates to that type of motor in which rotation is produced by means of the attraction and repulsion of surfaces.

According to this invention a stator and rotor are formed of condensor surfaces and charges of electricity.

The invention is more particularly with reference to the accompanying drawing in which:

Figure 1 shows a simple form of motor and feed.

The inner plates of the condenser 7, 8 connected to a source of energy of sufficiently high pressure (alternating or direct current), until the potential has ris springs over.

The spark gap 7, 8 forms with the condenser 5 and self-inductance 9 and condenser 6 a closed oscillatory circuit and alternating currents of high frequency w this circuit. Currents of the same periodicity.

The improved type of motor is fed by the discharges produced by the induction in the secondary circuit.

Hitherto only Tesla's motor system (shown diagrammatically in Figures 1, 16 and 17) was known for this purpose. The above-mentioned diagram is only sho the fundamental principle. It has no practical interest for carrying out large machines by reason of the impossibility of the regulation and the low efficiency.

All of these processes will be overcome by the construction of a machine which is applicable for high frequencies. The difference between the principle of co motors as compared to those of the principle of magnetic induction only (as they have been all motors hitherto and also Tesla's motors).

It will be fed directly with a static electricity but if it is connected to a source of high frequency current it will operate.

The applicants call this new type of motors 'condenser motors' to differentiate them from the hitherto existing types.

The simplest form of construction of such condenser motors is shown in Figure 1, and this motor can be fed with high frequency alternating currents.

To a moment of positive energy is charged by means of the lead 14 to the stator surface 1 and to the brush 3x (Figure 1). The 3x brush is connected with the that both the surface stator and the rotor surface 3 is charged with positive electricity. The stator surface 1 and the rotor surface 3 and the rotor surfaces 3 an with negative electricity, such motors can be a version of the alternating current in a manner similar to the starting of the synchronous motors of known constru

Although this motor is easy to start it can only be employed for small experimental and measuring purposes because the stator and rotor surfaces are made of s heated by Foucalt (eddy) currents. In spite of its simplicity and its unsuitability for use in practice it must however be regarded as a basic type for technical calc

The condenser motor shown in Figure 2 differs from Figure 1 by the rotor surfaces consisting of six condenser surfaces connected one behind the other in s connected with three collector surfaces, so that at any one moment only two adjacent collector surfaces come under the two brushes (3 and 4). In its other acti to Figure 1. The leads 14 and 15 may be connected either to the ends of the secondary coil 10 or directly with the source of energy. The outer thicker line i surfaces 1 and 2 (that is to say the unmoving part of the motor), 11 and 12 shown by thick dotted lines means earthed additional poles of the stator, 8, 9, an parts of the rotor condenser surfaces which in turn are connected with the collector surfaces 8, 9, and 10. 5, 6, and 7 are the inner parts of the condenser surfac 3 and 4 are brushes.

Hitherto stator and rotor surfaces. These conditions become highly heated with eddy currents and hardly yield 10-15% of useful effect. It is found in certain the stator and condenser surfaces. It was not possible to be cut in the metal surface of the stator and rotor in the form of a spiral, not only was it to be improved.

Experiments have shown that this is possible to build a very useful motor for high frequency alternating currents more particularly those of an undamped natur

Shown in Figure 1, but with the model shown below in Figure 5, but with the form of construction of the condensers of the stator as well as of the rotor accor condenser motor is obtained which works well in either direction for high frequency alternating current. It was also observed that the motors in such forms of found to be sensitive to resonance effects. Such a motor can be used in the same way if the winder is in the stator and also in the rotor.

A motor construction according to the foregoing kind is already fully technically applicable. But even these motors have a series of faults, more particularl construction. For example, the attachment of the spiral condenser both in the stator and of the rotor sown in Figure 3 are in practice difficult to carry out. In shown in Figure 4. These stator and rotor surfaces may be without further difficulty, be considered as electromagnetic poles, although they are not made of electromagnets.

In the case of the coil as shown in Figure 4, the coil can be embedded in insulating material or as the motorist as it has been done in the case of ordinary sin motors. To the same time the possibility is afforded by increasing the number of changes to the individual induction co-efficients.

In Figure 5 is shown a modified construction of a capacitor surfaces 1, 2, 3, 4, of which 1 and 2 are connected though an iductance 9 coupled with the c surfaces 5 , 6, 7, 8 are provided of which 5 and 6 are connected directly 7 and 8 similarly connected.

The pair of like poles are connected by wires 14 and 15 to the source of energy. By a suitable selection of the values of the reactance and capacity in these circu

We have been able to do this, and we will be able to declare what we claim is: --- [Claims not included here]

British Patent # 157,263

Process and Apparatus for Converting Static

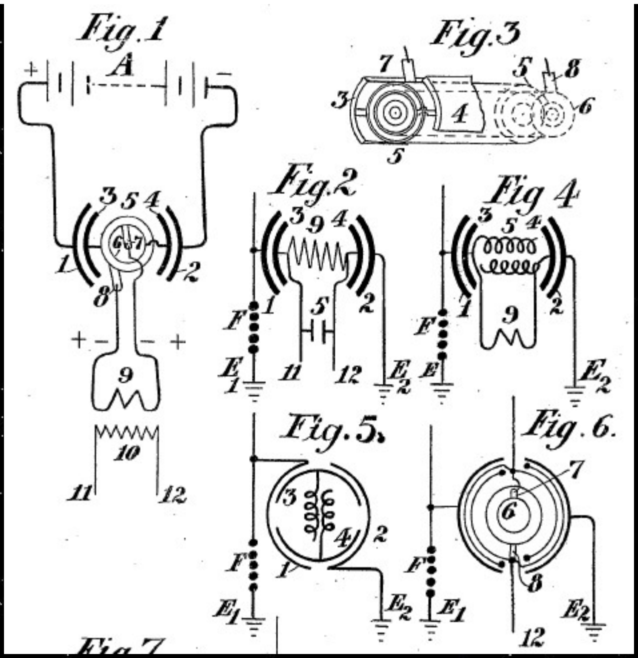
Hermann Plauson // HO Traun's Forschungs-Laboratorium GmbH

In the form of direct current in the form of a direct current in the form of a wave in the form of a direct current in the form or by means of a special kin 'condenser motors' --- ready to be used for technical purposes as mechanical energy.

For small installations, this system may be very well employed; about 100 horsepower may be stated as practical limit. In constructions of larger aggregate dif the spark gaps however increase considerably. It can be used as an alternative to a number of alternatives.

British Patent # 157,262 It was observed that the rotor, if one pole of the stator was connected to the air, collecting aerial electricity and the other pole with could a motor, but if vice versa the rotor connection with the stator be interrupted and the rotor caused to rotate by means of another motor, that when t alternating current the periodicity of which is dependent on the number of poles and the revolutions of the rotor. Such an apparatus may be considered as static into dynamic electrical energy.

The invention is more particularly with reference to the accompanying diagrams in which:



In Figure 1A is a strong accumulator battery, 1 and 2 are the outer poles of the transformer, consisting of simple metallic plates as shown in Figures 8-11, m without an electromagnet being present. These armors are similar to cylindrically curved plates 3 and 4. These are metallically connected with two collectors which two brushes 7 and 8 freely run which again are short 11- 12: If the accumulator battery is used with the free ends 11 and 12. 3 which is connected by th over the primary coil 9 with the second rotor surface 4. This is the case that you are using, if you are in the current circuit, or if you are in the same circu mechanical power, the rotor, the surface conditions are altered. After a revolution the plates are between the stator plates and therefore no condenser surface This is the case for the entire system. 9. Now if the rotor is turned further through 90 degrees by mechanical energy the rotor plate 3 plate 2 and the rotor pla stator plate 1, so that the rotor pates in a field of reverse sign. The first condition is again produced. The result of such a revolution is an alternating current which is equal to the number of revolution. In practice of course, not two poles but many poles as possible would be to increase the number of alternati alternating current thus obtained from the winding of the coil. Figure 7 shows a multipolar machine. The first condition is again produced. The result of such alternating current the periodicity of which is equal to the number of revolution. In practice of course, not two poles but many poles as possible would be to inc of alternations. The primary alternating current thus obtained from the winding of the coil. Figure 7 shows a multipolar machine. The first condition is aga result of such a revolution is an alternating current the periodicity of which is equal to the number of revolution. In practice of course, not two poles but as would have been to increase the number of alternations. The primary alternating current thus obtained from the winding of the coil. Figure 7 shows a multipo result of such a revolution is an alternating current the periodicity of which is equal to the number of revolution. In practice of course, not two poles but many would be to increase the number of alternations. The primary alternating current thus obtained from the winding of the coil. Figure 7 shows a multipolar mach such a revolution is an alternating current the periodicity of which is equal to the number of revolution. In practice of course, not two poles but many poles as p to increase the number of alternations. The primary alternating current thus obtained from the winding of the coil. Figure 7 shows a multipolar machine. The pr current thus obtained from the winding of the coil. Figure 7 shows a multipolar machine. The primary alternating current thus obtained from the winding of shows a multipolar machine.

If the stator surface 2, but the rotor wich is otherwise constructed as hereinbefore, be rotated by a separate motor a much stronger alternating current result ascribed to the pole of the stator by reason of the higher pressure of the static electricity than where accumulators are employed. By this means the transformer scope of supply to it.

Figure 2 shows a mode of connections. The stator surface 1 is connected to the aerial antennae which is connected through the safety spark gap F to earth surface 2 is directly earthed at E2. The inner revoluble rotor surfaces 3 and 4 are interconnected by means of an induction coil which is constructed directly current is assumed as in Figure 1, to be shown for the sake of clearness, and further conveyed through the 11 and 12 conductors. There is a short circuit oscill spark gaps, which circuit consists of the induction coil 9 and condenser 5 and is fed by the periodic charging current impulse. This is the possibility of ob current which is characterized by longer periods and is undamped and oscillatory. Of course a simple alternating current may be obtained by cutting the conden

Instead of the induction coil the condenser may also be b constructed in the rotor. It can be carried out in such a way that it serves directly as collector rings through the brushes. In Figure 3 such a motor is sketched in perspective, 3 and 4 are the rotor surfaces, 5 and 6 are the condenser surfaces constructed to form consisting of two co-axial cylinders fitting free on the brushes 7 on one end of the condenser cylinder 6.

Is shown in Figure 4. A further type of transformer is shown in Figure 5. The difference consists in the stator and rotor surfaces. of the circuit but almost the h condenser is better utilized. Full face of the stator surfaces.

In addition to condition is obtained in which the stator surfaces are inductively connected by the rotor surfaces. The connection is as before.

Figure 6 shows the alternation of the rotor surfaces; two cylindrical condenser plates arranged concentrically, each divided into two halves and connected so t cylinder is connected to half the outer. Transformer action.

Fig.7.

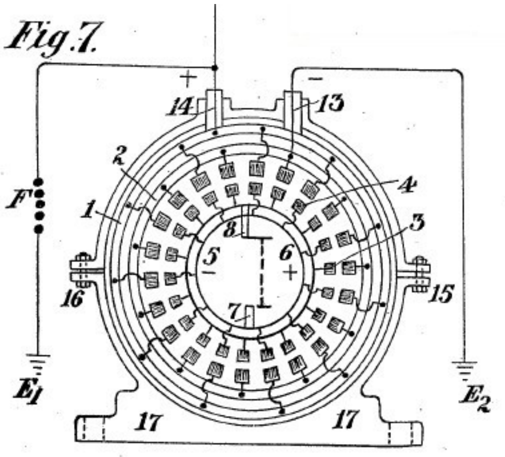


Figure 7 shows a four polar transformer. It consists of a metal casing, the lower half of which is fastened with the foundation plates. 17 to the support or foun
half, the cover, is connected by bolts 15 and 16 This upper sleeve or case is insulated from the under part. Two rings 1 and 2 are cylindrically constructed in th
1 is metallically connected with the collector and the ring 2 with the earth. On both rings and an equal number of stator surfaces are mounted side by side
from one another and thus form an electrostatic field similar to the electromagnetic in many alternating current machines. The rotor consists of the similarity o
6 on which an equal number of rotor surfaces are fixed. By the brushes 7 and 8 The charge is conveyed by the conductor 14 to and by 13 away. Alternating cu
the rotor, the periods of time are rotated by revolutions per second.

This article was previously published under Q140870 and was used as an alternative to a conversion to the friction. To the effect of the considerable energy
caused by a conductor being moved through strongly electrostatic fields since the electrostatic lines of force must be cut to the right angles and that to
apparatus should not only be regarded as a transformer, but also as an energy producer, with the difference that the excitation is here, instead of by means of ele
entire system may, to some extent, be applied with a dynamo in which the excitation takes place. It was further ascertained that this way of using the atmo
produced as a result of suction on the collector network.

The effects which in this instrument became evident are extremely interesting and open to the future. Merely that these transformers become already the extre
apparatus. If you are a future manufacturer, you will be able to produce a certain quantity of energy which may be constructed in the future. according to
system.

The results of the examinations made for this may be construed as follows.

(1) If solid electrodes (condenser surfaces, rotor and stator surfaces) are used they become hot. Ribbed form electromagnetism Figure 8, but not entirely re
allows the surface of the condenser plate to be enlarged or increased; the electrodes may be fastened in a simple manner on the under frame by perforation 1, 2,

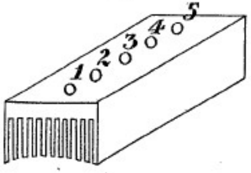

Fig. 9.

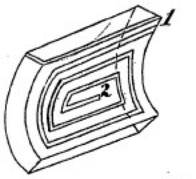

(2) If nicks or notches in spiral form as shown in Figure 9 seen from the side in Figure 10 in section are employed, not only is the transformer effect greater b
their movement than a simple commutator action would require.

Fig. 10

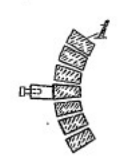

Fig. 11

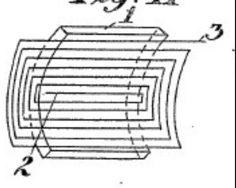

(3) The greatest effect is obtained if the rotor and stator surfaces are wound into a flat spiral form of suitably thick wire, and in that a way that the inductive ef
with the capacity suitable periodicity. In practice this is done by spiral wire (see Figure 11) so that a smooth pole is similar to that in phase motors.

Fig.12

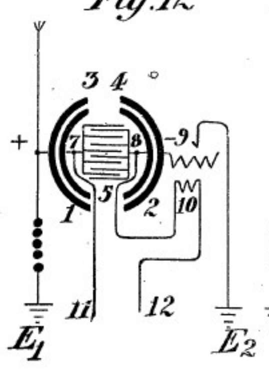

Fig. 13.

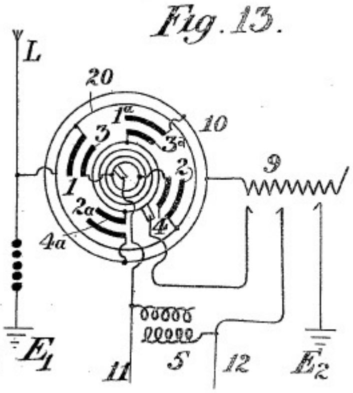
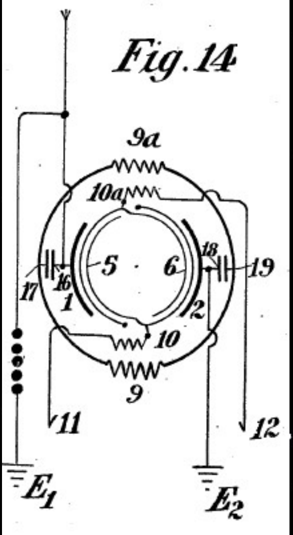
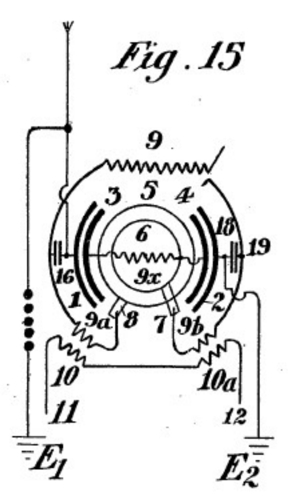


The aerial wire is shown in Figure 13. The aerial wire is shown in Figure 13. The aerial wire is connected to the ring. The inductive earth pole is also connec
ring 10 from which again two, poles 1a and 2a are branched off. Of course in the same manner any suitable number of poles may be branched of. In similar ma
two poles fastened to one another (3 and 4 and 3a and 4a) connected with separate collector rings. From these two rings the current is collected by means of
induced alternating current is however directly metallically connected with an inductive earth stator conductor over an induction coil 9. In parallel with the co
sparkless oscillatory circuit that can be applied to the exciting current in the stator. This produces however, a periodic alteration of the charge according to the
rotor currents in consequence of which the stator charge also commences with resonance oscillations and if the stator and rotor surfaces are calculated to ar
oscillations of waves of similar length the form of which is dependent on the amplitude of the main alternating current and is caused by the number of the pole
per second. Thus an alternating current of, for example, 100 periods of time is formed, the separated periods of which are formed by undamped oscillations o
of alternations. In Figures 14-16 four other diagrams of converters are shown, the object of which is not to produce the usual alternating current, but os
frequency.

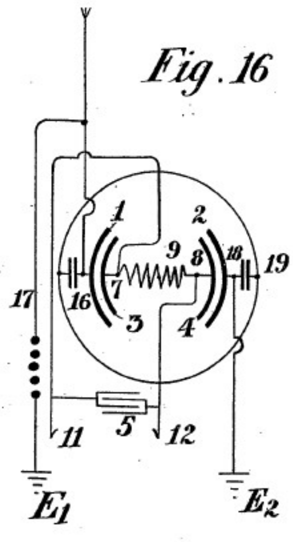
Fig.14



The main difference of these systems from the one that is already present in the stator pole 1 (Figure 14) and one pole 16 of the condenser 17 and the earth con
second stator pole 2 and the pole 18 of the condenser 19. The other poles of these condensers 17 and 19 are short circuited through a ring over two inductive p
9a with one another. The secondary coils form the rotor conductors 10 and 10a. The rotor itself is constructed in the manner shown in Figure 6. In similar man
stator surfaces may also be formed. The collector rings of the rotor with the two brushes for the collecting current are shown in order to simplify the drawings.
maximum action by the connection of the two alternating current and the alternating current produced in the rotor on the stator circuit, with a correct calculati
and the self-induction may be obtained. The kind of current production will be similar to that described for Figure 12.

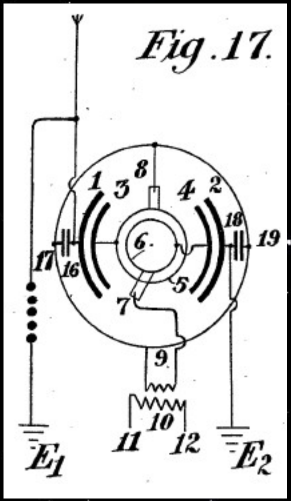


The novelty of the converter illustrated in Figure 15 consists mainly of the current in the rotor is not directly employed, but only serves the excitation of the pri 9b. The working current is produced in the secondary coils 10 and 10a and further conducted through the 11 and 12 conductors. The stator current may b regulatable inductive resistance to the same resonance as the rotor current.



In Figure 16 a very similar system is shown in Figure 14. The condenser 5 is connected in parallel with the converter; and in the rotor a short circuited os formed which gives extraordinarily good results and is simple in construction.

The inductive resistance may be considered as primary coil used outside the rotor and short circuit (see Figure 17).



The last six types serves only for producing oscillations of a high number of alternations. If it be desired to be ordinary alternating current there complicat arrangements are not required as the types illustrated in Figures 1 to 11 suffice. It is self-evident that these arrangements may be altered in various ways.
We have been able to describe this as well as the fact that we are doing it, we declare that what we claim is: --- [Claims not included here]

(57) **ABSTRACT**

Arrangement of resonators in an aperiodic configurations are described, which can be used for electromagnetic cloaking of objects. The overall assembly of resonators, as structures, do not all repeat periodically and at least some of the resonators are spaced such that their phase centers are separated by more than a wavelength. The arrangements can include resonators of several different sizes and/or geometries arranged so that each size or geometry corresponds to a moderate or high "Q" response that resonates within a specific frequency range, and that arrangement within that specific grouping of akin elements is periodic in the overall structure. The relative spacing and arrangement of groupings can be defined by self similarity and origin symmetry.

WIDEBAND ELECTROMAGNETIC CLOAKING SYSTEMS

RELATED APPLICATION

This application claims priority to U.S. Provisional Patent Application No. 61/189,966, filed 25 Aug. 2008 and entitled "Method and Apparatus for Wideband Electromagnetic Cloaking, Negative Refractive Index Lensing and Metamaterial Applications," the entire contents of which are incorporated herein by reference.

BACKGROUND

Much time and effort has been devoted to the quest for so-called invisibility machines. Beyond science fiction, however, there has been little if any real progress toward this goal.

Materials with negative permittivity and permeability leading to negative index of refraction were theorized by Russian noted physicist Victor Veselago in his seminal paper in *Soviet Physics* USPEKHI, 10, 509 (1968). Since that time, metamaterials have been developed that produce negative index of refraction, subject to various constraints. Such materials are artificially engineered micro/nanostructures that, at given frequencies, show negative permeability and permittivity. Metamaterials have been shown to produce narrow band, e.g., typically less than 5%, response such as bent-back lensing. Such metamaterials produce such a negative-index effect by utilizing a closely-spaced periodic lattice of resonators, such as split-ring resonators, that all resonate. Previous metamaterials provide a negative index of refraction when a sub-wavelength spacing is used for the resonators.

In the microwave regime, certain techniques have been developed to utilize radiation-absorbing materials or coatings to reduce the radar cross section of airborne missiles and vehicles. While such absorbing materials can provide an effective reduction in radar cross section, these results are largely limited to small ranges of electromagnetic radiation.

SUMMARY

Embodiments of the present disclosure can provide techniques, including systems and/or methods, for cloaking objects at certain wavelengths/frequencies or over certain wavelength/frequency ranges (bands). Such techniques can provide an effective electromagnetic lens and/or lensing effect for certain wavelengths/frequencies or over certain wavelength/frequency ranges (bands).

The effects produced by such techniques can include cloaking or so-called invisibility of the object(s) at the noted wavelengths or bands. Representative frequencies of operation can include, but are not limited to, those over a range of 500 MHz to 1.3 GHz, though others may of course be realized. Operation at other frequencies, including for example those of visible light, infrared, ultraviolet, and as well as microwave EM radiation, e.g., K, Ka, X-bands, etc. may be realized, e.g., by appropriate scaling of dimensions and selection of shape of the resonator elements.

Exemplary embodiments of the present disclosure can include a novel arrangement of resonators in an aperiodic configuration or lattice. The overall assembly of resonators, as structures, do not all repeat periodically and at least some of the resonators are spaced such that their phase centers are separated by more than a wavelength. The arrangements can include resonators of several different sizes and/or geometries arranged so that each size or geometry ("grouping") corresponds to a moderate or high "Q" (that is moderate or low bandwidth) response that resonates within a specific frequency range, and that arrangement within that specific grouping of akin elements is periodic in the overall structure—even though the structure as a whole is not an entirely periodic arrangement of resonators. The relative spacing and arrangement of groupings (at least one for each specific frequency range) can be defined by self similarity and origin symmetry, where the "origin" arises at the center of a structure (or part of the structure) individually designed to have the wideband metamaterial property.

For exemplary embodiments, fractal resonators can be used for the resonators in such structures because of their control of passbands, and smaller sizes compared to non-fractal based resonators. Their benefit arises from a size standpoint because they can be used to shrink the resonator (s), while control of passbands can reduce or eliminates issues of harmonic passbands that would resonate at frequencies not desired.

It should be understood that other embodiments of wideband electromagnetic resonator or cloaking systems and methods according to the present disclosure will become readily apparent to those skilled in the art from the following detailed description, wherein exemplary embodiments are shown and described by way of illustration. The systems and methods of the present disclosure are capable of other and different embodiments, and details of such are capable of modification in various other respects. Accordingly, the drawings and detailed description are to be regarded as illustrative in nature and not as restrictive.

BRIEF DESCRIPTION OF THE DRAWINGS

Aspects of the disclosure may be more fully understood from the following description when read together with the accompanying drawings, which are to be regarded as illustrative in nature, and not as limiting. The drawings are not necessarily to scale, emphasis instead being placed on the principles of the disclosure. In the drawings:

FIG. **1** depicts a diagrammatic plan view of a resonator cloaking system utilizing a number of cylindrical shells, in accordance with exemplary embodiments of the present disclosure;

FIG. **2** depicts a diagrammatic plan view of a resonator cloaking system utilizing a number of shells having an elliptical cross-section, in accordance with an alternate embodiment of the present disclosure;

FIG. **3** depicts an exemplary embodiment of a portion of shell that includes repeated conductive traces that are configured in a fractal-like shape; and

FIG. **4** depicts a perspective view (photograph) of an exemplary embodiment of the present disclosure.

While certain embodiments depicted in the drawings, one skilled in the art will appreciate that the embodiments depicted are illustrative and that variations of those shown, as well as other embodiments described herein, may be envisioned and practiced within the scope of the present disclosure.

DETAILED DESCRIPTION

The present disclosure is directed to novel arrangements of resonators useful for obscuring or hiding objects at given bands of electromagnetic radiation. Embodiments of the present disclosure can provide techniques, including systems and/or methods, for hiding or obscuring objects at certain wavelengths/frequencies or over certain wavelength/frequency ranges or bands. Such techniques can provide an

effective electromagnetic lens and/or lensing effect for certain wavelengths/frequencies or over certain wavelength/frequency ranges or bands. The effects produced by such techniques can include cloaking or so-called invisibility of the object(s) at the noted wavelengths or bands.

Representative frequencies of operation can include, but are not limited to, those over a range of about 500 MHz to about 1.3 GHz, though others may of course be realized. Operation at other frequencies, including for example those of visible light, infrared, ultraviolet, and as well as microwave EM radiation, e.g., K, Ka, X-bands, etc. may be realized, e.g., by appropriate scaling of dimensions and selection of shape of the resonator elements.

Embodiments of the present disclosure include arrangement of resonators or resonant structures in aperiodic configurations or lattices. The overall assembly of resonator structures can include nested or concentric shells, that each include repeated patterns of resonant structures. The resonant structures can be configured as a close-packed arrangement of electrically conductive material. The resonant structures can be located on the surface of a circuit board.

The overall assemblies, as structures, do not all repeat periodically and at least some of the resonators are spaced such that their phase centers are separated by more than a wavelength. The arrangements can include resonators of several different sizes and/or geometries arranged so that each size or geometry ("grouping") corresponds to a moderate or high quality-factor "Q" response (that is, one allowing for a moderate or low bandwidth) that resonates within a specific frequency range, and that arrangement within that specific grouping of like elements is periodic in the overall structure—even though the structure as a whole is not an entirely periodic arrangement of resonators. The relative spacing and arrangement of groupings (at least one for each specific frequency range) can be defined by self similarity and origin symmetry, where the "origin" arises at the center of a structure (or part of the structure) individually designed to have the wideband metamaterial property.

For exemplary embodiments, fractal resonators can be used for the resonators because of their control of passbands, and smaller sizes. A main benefit of such resonators arises from a size standpoint because they can be used to shrink the resonator(s), while control of passbands can reduce/mitigate or eliminate issues of harmonic passbands that would resonate at frequencies not desired.

Exemplary embodiments of a resonator system for use at microwave (or nearby) frequencies can be built from belts of circuit boards festooned with resonators. These belts can function to slip the microwaves around an object located within the belts, so the object is effectively invisible and "see thru" at the microwave frequencies. Belts, or shells, having similar closed-packed arrangements for operation at a first passband can be positioned within a wavelength of one another, e.g., $\frac{1}{10}\lambda$, $\frac{1}{8}\lambda$, $\frac{1}{4}\lambda$, $\frac{1}{2}\lambda$, etc.

An observer can observe an original image or signal, without it being blocked by the cloaked object. Using no power, the fractal cloak can replicates the original signal (that is, the signal before blocking) with great fidelity. Exemplary embodiments can function over a bandwidth from about 500 MHz to approximately 1500 MHz (1.5 GHz), providing 3:1 bandwidth; operation within or near such can frequencies can provide other bandwidths as well, such as 1:1 up to 2:1 and up to about 3:1.

FIG. **1** depicts a diagrammatic plan view of a cloaking system **100** and RF testing set up in accordance with exemplary embodiments of the present disclosure. As shown in FIG. **1**, a number of concentric shells (or bands) **102** are placed on a platform (parallel to the plane of the drawing). The shells include a flexible substrate (e.g., polyimide with or without composite reinforcement) with conductive traces (e.g., copper, silver, etc.) in fractal shapes or outlines. The shells **102** surround an object to be cloaked (shown as **104** in FIG. **1**). A transmitting antenna **1** and a receiving antenna **2** are configured at different sides of the system **100**, for verifying efficacy of the cloaking system **100** and recording results. The shells **102** can be held in place by radial supports **106** (while only four are shown, **12** were used in the exemplary embodiment indicated).

The shells indicated in FIG. **1** are of two types, one set (A**1**-A**4**) configured for optimal operation over a first wavelength/frequency range, and another set (B**1**-B**3**) configured for optimal operation over a second wavelength/frequency range. (The numbering of the shells is of course arbitrary and can be reordered, e.g., reversed.)

For an exemplary embodiment of system **100**, the outer set of shells (A**1**-A**4**, with A**1** being the innermost and A**4** the outmost) had a height of about 3 to 4 inches (e.g., 3.5 inches) and the inner set of shells had a height of about 1 inch less (e.g., about 2.5 to 3 inches). The spacing between the shells with a larger fractal shape (A**1**-A**4**) was about 2.4 cm while the spacing between shells of smaller fractal generator shapes (B**1**-B**3**) was about 2.15 cm (along a radial direction). In a preferred embodiment, shell A**4** was placed between shell B**2** and B**3** as shown. The resonators formed on each shell by the fractal shapes can be configured so as to be closely coupled (e.g., by capacitive coupling) and can serve to propagate a plasmonic wave.

It will be appreciated that while, two types of shells and a given number of shells per set are indicated in FIG. **1**, the number of shell types and number of shells for each set can be selected as desired, and may be optimized for different applications, e.g., wavelength/frequency bands.

FIG. **2** depicts a diagrammatic plan view of a cloaking system (or electrical resonator system) according to an alternate embodiment in which the individual shells have an elliptical cross section. As shown in FIG. **2**, a system **200** for cloaking can include a number of concentric shells (or bands) **202**. These shells can be held in place with respect to one another by suitable fixing means, e.g., they can be placed on a platform (parallel to the plane of the drawing) and/or held with a frame. The shells **202** can include a flexible substrate (e.g., polyimide with or without composite reinforcement) with a close-packed arrangement of electrically conductive material formed on the first surface. As stated previously for FIG. **1**, the closed-packed arrangement can include a number of self-similar electrical resonator shapes. The resonator shapes can be made from conductive traces (e.g., copper, silver, gold, silver-based ink, etc.) having a desired shape, e.g., fractal shape, split-ring shape, and the like. The shells **202** can surround an object to be cloaked, as indicated in FIG. **2**.

As indicated in FIG. **2** (by dashed lines **1** and **2** and arrows), the various shells themselves do not have to form closed surfaces. Rather, one or more shells can form open surfaces. This can allow for preferential cloaking of the object in one direction or over a given angle (solid angle). Moreover, while dashed lines **1** and **2** are shown intersecting shells B**1**-B**3** and A**1**-A**3** of system **200**, one or more shells of each group of shells (B**1**-B**3** and A**1**-A**3**) can be closed while others are open.

With further regard to FIGS. **1**-**2**, it should be appreciated that the cross-sections shown for each shell can represent closed geometric shapes, e.g., spherical and ellipsoidal shells.

As indicated previously, each shell of a cloaking system can include multiple resonators. The resonators can be repeated patterns of conductive traces. These conductive traces can be closed geometric shapes, e.g., rings, loops, closed fractals, etc. The resonator(s) can being self similar to at least second iteration. The resonators can include split-ring shapes, for some embodiments. The resonant structures are not required to be closed shapes, however, and open shapes can be used for such.

In exemplary embodiments, the closed loops can be configured as a fractals or fractal-based shapes, e.g., as depicted by **302** in FIG. **3** for an exemplary embodiment of a shell **300**, or **402** in FIG. **4**. The dimensions and type of fractal shape can be the same for each shell type but can vary between shell types. This variation (e.g., scaling of the same fractal shape) can afford increased bandwidth for the cloaking characteristics of the system (e.g., system **100** of FIG. **1**) This can lead to periodicity of the fractal shapes of common shell types but aperiodicity between the fractal shapes of different shell types.

Examples of suitable fractal shapes (for use for shells and/or a scatting object) can include, but are not limited to, fractal shapes described in one or more of the following patents, owned by the assignee of the present disclosure, the entire contents of all of which are incorporated herein by reference: U.S. Pat. Nos. 6,452,553; 6,104,349; 6,140,975; 7,145,513; 7,256,751; 6,127,977; 6,476,766; 7,019,695; 7,215,290; 6,445,352; 7,126,537; 7,190,318; 6,985,122; 7,345,642; and, U.S. Pat. No. 7,456,799.

Other suitable fractal shape for the resonant structures can include any of the following: a Koch fractal, a Minkowski fractal, a Cantor fractal, a torn square fractal, a Mandelbrot, a Caley tree fractal, a monkey's swing fractal, a Sierpinski gasket, and a Julia fractal, a contour set fractal, a Sierpinski triangle fractal, a Menger sponge fractal, a dragon curve fractal, a space-filling curve fractal, a Koch curve fractal, an Iypanov fractal, and a Kleinian group fractal.

FIG. **3** depicts an exemplary embodiment of a shell **300** (only a portion is shown) that includes repeated conductive traces that are configured in a fractal shape **302** (the individual closed traces). For the exemplary embodiment shown, each resonator shape **302** is about 1 cm on a side. Such resonator could, e.g., be used for the fractal shapes of shells B**1**-B**3** of FIG. **1**, in which case similar fractal shapes of larger size (e.g., about 1.5 cm on a side) could be used for shells A**1**-A**4**. The conductive trace is preferably made of copper. While exemplary fractal shapes are shown in FIG. **3**, the present disclosure is not limited to such and any other suitable fractal shapes (including generator motifs) may be used in accordance with the present disclosure.

It will be appreciated that the resonant structures of the shells may be formed or made by any suitable techniques and with any suitable materials. For example, semiconductors with desired doping levels and dopants may be used as conductive materials. Suitable metals or metal containing compounds may be used. Suitable techniques may be used to place conductors on/in a shell, including, but no limited to, printing techniques, photolithography techniques, etching techniques, and the like.

It will also be appreciated that the shells may be made of any suitable material(s). Printed circuit board materials may be used. Flexible circuit board materials are preferred. Other material may, however, be used for the shells and the shells themselves can be made of non-continuous elements, e.g., a frame or framework. For example, various plastics may be used.

FIG. **4** depicts a perspective view (photograph) of an exemplary embodiment of a cloak system **400** according to the present disclosure. As shown, the system includes a number of resonator shells **402** each having a close-packed arrangement of electrically conductive material (self-similar resonators **404**) formed on one surface. Two different shell configurations are shown, four larger shells and two smaller shells. The smaller shells included close-packed arrangements of resonator structures in which each resonator shape (as shown by **302** in FIG. **3**) was about 1 cm on a side. Similar fractal shapes of larger size (e.g., about 1.5 cm on a side) were used for the larger shells.

In FIG. **4**, a transmitting (source) antenna and a receiving antenna are shown as triangular shapes on the left and right, respectively (though functionally of each could of course be interchanged for the other). Twelve radially arrayed spacers are shown in FIG. **4**. The system **400** is shown supported on a Nalgene tank and Delrin platform and Delrin supports (radial supports) RF absorbers were placed in the immediate vicinity of the set up; further RF tripods (e.g., available from ETS) were used; all such materials were substantially transparent at the RF frequencies investigated/used. The cloak system **400** consists of six belts of fractal metamaterial (i.e., fractal-resonant structures shown in FIG. **3**) on flexible Taconic EF35 (low loss) circuit board. The belts are shown surround a scattering ring (object). The arrangement is supported by RF transparent plastics in a comb support. The entire system **400** was shown to be easily built up and broken down within a minute or two. The scale in FIG. **4** is about 0.7 meters across. The height of each shell can of course be selected as desired depending on the situation/application.

While embodiments are shown and described herein as having shells in the shape of concentric rings (circular cylinders), shells can take other shapes in other embodiments. For example, one or more shells could have a generally spherical shape (with minor deviations for structural support). In an exemplary embodiment, the shells could form a nested arrangement of such spherical shapes, around an object to be shielded (at the targeted/selected frequencies/wavelengths). Shell cross-sections of angular shapes, e.g., triangular, hexagonal, while not preferred, may be used.

One skilled in the art will appreciate that embodiments and/or portions of embodiments of the present disclosure can be implemented in/with computer-readable storage media (e.g., hardware, software, firmware, or any combinations of such), and can be distributed and/or practiced over one or more networks. Steps or operations (or portions of such) as described herein, including processing functions to derive, learn, or calculate formula and/or mathematical models utilized and/or produced by the embodiments of the present disclosure, can be processed by one or more suitable processors, e.g., central processing units ("CPUs") implementing suitable code/instructions in any suitable language (machine dependent on machine independent).

While certain embodiments and/or aspects have been described herein, it will be understood by one skilled in the art that the methods, systems, and apparatus of the present disclosure may be embodied in other specific forms without departing from the spirit thereof.

For example, while certain wavelengths/frequencies of operation have been described, these are merely representative and other wavelength/frequencies may be utilized or achieved within the scope of the present disclosure.

Furthermore, while certain preferred fractal generator shapes have been described others may be used within the scope of the present disclosure. Accordingly, the embodi-

ments described herein are to be considered in all respects as illustrative of the present disclosure and not restrictive.

What is claimed is:

1. An electrical resonator system, comprising:

a plurality of concentric electrical resonator shells, each shell including a substrate having first and second surfaces and a close-packed arrangement of electrically conductive material formed on the first surface, wherein the closed-packed arrangement comprises a plurality of self-similar electrical resonator shapes and is configured to operate at a desired passband of electromagnetic radiation;

wherein the close-packed arrangements of at least two of the electrical resonator shells are different in size and/or shape; and

wherein a resonator in the close-packed arrangement comprises a second order or higher fractal.

2. The system of claim **1**, wherein said passband is about 2:1.

3. The system of claim **2**, wherein said passband is about 3:1.

4. The system of claim **1**, wherein the electrical system is configured and arranged so that radiation incident on the system from a given direction has an intensity on a point-by-point basis such at each respective antipodal point, relative to an object placed at the center of the system, the radiation has the same or similar intensity.

5. The system of claim **1**, wherein the system is configured and arranged so that radiation incident on the system from a direction in cylindrical coordinates has the same or similar intensity at the antipodal point after having traversed the system.

6. The system of claim **1**, wherein the plurality of shells comprises a first pair of shells having similar closed-packed arrangements for operation at a first passband, wherein the two shells are positioned within ⅛λ of one another.

7. The system of claim **6**, wherein the plurality of shells comprises a second pair of shells having similar closed-packed arrangements for operation at a second frequency band, wherein the two shells are positioned within ⅛λ of one another.

8. The system of claim **1**, wherein the plurality of shells are hemispherical.

9. The system of claim **1**, wherein the plurality of shells are cylindrical.

10. The system of claim **1**, wherein the plurality of shells are spherical.

11. The system of claim **1**, wherein said fractal is selected from the group consisting of a Koch fractal, a Minkowski fractal, a Cantor fractal, a torn square fractal, a Mandelbrot, a Caley tree fractal, a monkey's swing fractal, a Sierpinski gasket, and a Julia fractal.

12. The system of claim **1**, wherein the fractal is selected from the group consisting of a contour set fractal, a Sierpinski triangle fractal, a Menger sponge fractal, a dragon curve fractal, a space-filling curve fractal, a Koch curve fractal, a Lypanov fractal, and a Kleinian group fractal.

13. The system of claim **1**, wherein the plurality of concentric electrical resonator shells are configured and arranged for operation at K band, Ka band, or X-band.

14. The system of claim **1**, wherein the system is operational over a bandwidth from about 500 MHz to about 1500 MHz.

[57] **ABSTRACT**

A system is disclosed for converting high frequency zero point electromagnetic radiation energy to electrical energy. The system includes a pair of dielectric structures which are positioned proximal to each other and which receive incident zero point electromagnetic radiation. The volumetric sizes of the structures are selected so that they resonate at a frequency of the incident radiation. The volumetric sizes of the structures are also slightly different so that the secondary radiation emitted therefrom at resonance interfere with each other producing a beat frequency radiation which is at a much lower frequency than that of the incident radiation and which is amenable to conversion to electrical energy. An antenna receives the beat frequency radiation. The beat frequency radiation from the antenna is transmitted to a converter via a conductor or waveguide and converted to electrical energy having a desired voltage and waveform.

SYSTEM FOR CONVERTING ELECTROMAGNETIC RADIATION ENERGY TO ELECTRICAL ENERGY

BACKGROUND OF THE INVENTION

The invention relates generally to conversion of electromagnetic radiation energy to electrical energy, and, more particularly, to conversion of high frequency bandwidths of the spectrum of a type of radiation known as zero point electromagnetic radiation to electrical energy.

The existence of zero point electromagnetic radiation was discovered in 1958 by the Dutch physicist M. J. Sparnaay. Mr. Sparnaay continued the experiments carried out by Hendrik B. G. Casimir in 1948 which showed the existence of a force between two uncharged parallel plates which arose from electromagnetic radiation surrounding the plates in a vacuum. Mr. Sparnaay discovered that the forces acting on the plates arose from not only thermal radiation but also from another type of radiation now known as classical electromagnetic zero point radiation. Mr. Sparnaay determined that not only did the zero point electromagnetic radiation exist in a vacuum but also that it persisted even at a temperature of absolute zero. Because it exists in a vacuum, zero point radiation is homogeneous and isotropic as well as ubiquitous. In addition, since zero point radiation is also invariant with respect to Lorentz transformation, the zero point radiation spectrum has the characteristic that the intensity of the radiation at any frequency is proportional to the cube of that frequency. Consequently, the intensity of the radiation increases without limit as the frequency increases resulting in an infinite energy density for the radiation spectrum. With the introduction of the zero point radiation into the classical electron theory, a vacuum at a temperature of absolute zero is no longer considered empty of all electromagnetic fields. Instead, the vacuum is now considered as filled with randomly fluctuating fields having the zero point radiation spectrum. The special characteristics of the zero point radiation which are that it has a virtually infinite energy density and that it is ubiquitous (even present in outer space) make it very desirable as an energy source. However, because high energy densities exist at very high radiation frequencies and because conventional methods are only able to convert or extract energy effectively or efficiently only at lower frequencies at which zero point radiation has relatively low energy densities, effectively tapping this energy source has been believed to be unavailable using conventional techniques for converting electromagnetic energy to electrical or other forms of easily useable energy. Consequently, zero point electromagnetic radiation energy which may potentially be used to power interplanetary craft as well as provide for society's other needs has remained unharnessed.

There are many types of prior art systems which use a plurality of antennas to receive electromagnetic radiation and provide an electrical output therefrom. An example of such a prior art system is disclosed in U.S. Pat. No. 3,882,503 to Gamara. The Gamara system has two antenna structures which work in tandem and which oscillate by means of a motor operatively attached thereto in order to modulate the radiation reflected from the antenna surfaces. The reflecting surfaces of the antennas are also separated by a distance equal to a quarter wavelength of the incident radiation. However, the Gamara system does not convert the incident radiation to electrical current for the purpose of converting the incident electromagnetic radiation to another form of readily useable energy. In addition, the relatively large size of the Gamara system components make it unable to resonate at and modulate very high frequency radiation.

What is therefore needed is a system which is capable of converting high frequency electromagnetic radiation energy into another form of energy which can be more readily used to provide power for transportation, heating, cooling as well as various other needs of society. What is also needed is such a system which may be used to provide energy from any location on earth or in space.

SUMMARY OF THE INVENTION

It is a principle object of the present invention to provide a system for converting electromagnetic radiation energy to electrical energy.

It is another object of the present invention to provide a system for converting electromagnetic radiation energy having a high frequency to electrical energy.

It is another object of the present invention to provide a system for converting zero point electromagnetic radiation energy to electrical energy.

It is another object of the present invention to provide a system for converting electromagnetic radiation energy to electrical energy which may used to provide such energy from any desired location on earth or in space.

It is another object of the present invention to provide a system for converting electromagnetic radiation energy to electrical energy having a desired waveform and voltage.

It is an object of the present invention to provide a miniaturized system for converting electromagnetic radiation energy to electrical energy in order to enhance effective utilization of high energy densities of the electromagnetic radiation.

It is an object of the present invention to provide a system for converting electromagnetic radiation energy to electrical energy which is simple in construction for cost effectiveness and reliability of operation.

Essentially, the system of the present invention utilizes a pair of structures for receiving incident electromagnetic radiation which may be propagating through a vacuum or any other medium in which the receiving structures may be suitably located. The system of the present invention is specifically designed to convert the energy of zero point electromagnetic radiation; however, it may also be used to convert the energy of other types of electromagnetic radiation. The receiving structures are preferably composed of dielectric material in order to diffract and scatter the incident electromagnetic radiation. In addition, the receiving structures are of a volumetric size selected to enable the structures to resonate at a high frequency of the incident electromagnetic radiation based on the parameters of frequency of the incident radiation and propagation characteristics of the medium and of the receiving structures. Since zero point radiation has the characteristic that its energy density increases as its frequency increases, greater amounts of electromagnetic energy are available at higher frequencies. Consequently, the size of the structures are preferably miniaturized in order to produce greater amounts of energy from a system located within a space or area of a given size. In this regard, the smaller the size of the receiving structures, the greater the amount of energy that can be produced by the system of the present invention.

At resonance, electromagnetically induced material deformations of the receiving structures produce secondary fields of electromagnetic energy therefrom which may have eva-

nescent energy densities several times that of the incident radiation. The structures are of different sizes so that the secondary fields arising therefrom are of different frequencies. The difference in volumetric size is very small so that interference between the two emitted radiation fields, and the receiving structures at the two different frequencies produces a beat frequency radiation which has a much lower frequency than the incident radiation. The beat frequency radiation preferably is at a frequency which is sufficiently low that it may be relatively easily converted to useable electrical energy. In contrast, the incident zero point radiation has its desirable high energy densities at frequencies which are so high that conventional systems for converting the radiation to electrical energy either cannot effectively or efficiently so convert the radiation energy or simply cannot be used to convert the radiation energy for other reasons.

The system of the present invention also includes an antenna which receives the beat frequency radiation. The antenna may be a conventional metallic antenna such as a loop or dipole type of antenna or a rf cavity structure which partially encloses the receiving structures. The antenna feeds the radiation energy to an electrical conductor (in the case of a conventional dipole or comparable type of antenna) or to a waveguide (in the case of a rf cavity structure). The conductor or waveguide feeds the electrical current (in the case of the electrical conductor) or the electromagnetic radiation (in the case of the waveguide) to a converter which converts the received energy to useful electrical energy. The converter preferably includes a tuning circuit or comparable device so that it can effectively receive the beat frequency radiation. The converter may include a transformer to convert the energy to electrical current having a desired voltage. In addition, the converter may also include a rectifier to convert the energy to electrical current having a desired waveform.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** is a plan view of the receiving structures and antenna of a first embodiment of the system of the present invention with a schematic view of the conductor and converter thereof and also showing the incident primary and emitted secondary electromagnetic radiation.

FIG. **2** is a front view of the receiving structures, antenna and waveguide of a second embodiment of the system of the present invention with a schematic view of the converter thereof and also showing the incident primary and emitted secondary electromagnetic radiation.

FIG. **3** is a perspective view of the receiving structures, antenna and waveguide of the second embodiment shown in FIG. **2** with a schematic view of the converter thereof and also showing the incident primary and emitted secondary electromagnetic radiation.

FIG. **4** is a front view of the substrate and a plurality of pairs of the receiving structures and a plurality of antennas of a third embodiment of the system of the present invention with a schematic view of the conductor and converter thereof and also showing the incident primary and emitted secondary electromagnetic radiation.

FIG. **5** is a top view of some of the components of the third embodiment of the system of the present invention showing two of the plurality of pairs of receiving structures and two of the plurality of antennas mounted on the substrate.

FIG. **6** is a diagram of a receiving structure of the system of the present invention showing an incident electromagnetic plane wave impinging on the receiving structure and illustrating the directions of the electric and magnetic field vectors thereof.

FIG. **7** is a diagram of a spherical coordinate system as used in the formulas utilized in the system of the present invention.

FIG. **8** is a graph showing an imaginary ρ parameter plotted against a real ρ parameter illustrating the values thereof at resonance as well as values thereof at other than resonance.

FIG. **9** is a graph showing a portion of the graphical representation shown in FIG. **8** illustrating the real and imaginary ρ values at or near a single resonance.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

Referring to the drawings, a first embodiment of the present invention is generally designated by the numeral **10**. The system **10** includes a first and second means for receiving **12** and **14** incident electromagnetic radiation **16**. The means for receiving **12** and **14** are preferably a pair of spherical structures **12** and **14** which are preferably composed of a dielectric material. Alternatively, the spheres **12** and **14** may be cubical structures or any other suitable shape. The spheres **12** and **14** may be mounted on a suitable foundation by any suitable mounting means (not shown), or spheres **12** and **14** may be suspended from a suitable foundation by any suitable suspension means (not shown). The spheres **12** and **14** are preferably composed of a dielectric material. The dielectric spheres **12** and **14** scatter and concentrate electromagnetic waves. At very sharpely defined frequencies, the spheres **12** and **14** will have resonances wherein the internal energy densities can be five orders of mangitude larger than the energy density of the incident electromagnetic field driving the spheres **12** and **14**. At resonance, the electromagnetic stresses, equivalent to pressures proportional to the energy density, can cause material deformation of the spheres **12** and **14** which produce a secondary electromagnetic field. The spheres **12** and **14** are preferably positioned proximal to each other, as shown in FIG. **1**. Although the proximity of the spheres to each other will adversely affect the resonances, the very high "Q"s of the isolated-sphere resonances results in such adverse affect being relatively small. However, the proximity of the spheres **12** and **14** allows the spheres to interact electromechanically which increases the magnitude of the secondary radiation emitted therefrom.

The electromagnetic radiation incident upon the spheres **12** and **14** which drives the spheres to resonance is preferably zero point radiation **16**. However, other types of electromagnetic radiation may also be used to drive the spheres **12** and **14**, if desired.

The effect of a dielectric sphere such as **12** or **14** on an incident electromagnetic radiation such as a plane wave thereof is shown in FIG. **6**. The plane wave propagates in the z axis direction and is diffracted by the sphere **12** resulting in scattering thereof. This scattering is commonly known as Mie scattering. The incident radiation wave has an electric vector component which is linearly polarized in the x axis direction and a magnetic vector component which is linearly polarized in the y axis direction.

An electromagnetic wave incident upon a structure produces a forced oscillation of free and bound charges in synch with the primary electromagnetic field of the incident electromagnetic wave. The movements of the charges produce a

secondary electromagnetic field both inside and outside the structure. The secondary electromagnetic radiation comprising this secondary electromagnetic field is shown in FIG. **1** and designated by the numerals **18** and **20**. An antenna which is shown simply as a loop antenna but may also be a dipole or any other suitable type of antenna is also shown in FIG. **1** and designated by the numeral **22**. The nonlinear mutual interactions of the spheres produces interference between the secondary electromagnetic radiation **18** and **20** produces a beat frequency radiation **24** which is preferably at a much lower frequency than the primary radiation **16**. It is this beat frequency radiation **24** which is desired for conversion into electrical energy because it preferably is within the frequency range of rf radiation which may be converted into electrical energy by generally conventional systems. Thus, the radiation **24** received by the antenna **22** is fed via an electrical conductor **26** to a means for converting the beat frequency radiation **24** to electrical energy. This means for converting is designated by the numeral **28** and preferably includes a tuning capacitor **30** and a transformer **32** and a rectifier (preferably a diode) **34**. Instead of including the capacitor **30**, transformer **32** and rectifier **34**, the converter **28** may alternatively include an rf receiver of any suitable type.

The resultant field at any point is the vector sum of the primary and secondary fields. For the equations that follow, the structure receiving the incident plane wave is a sphere of radius a having a propagation constant k_1 positioned in an infinite, homogeneous medium having a propagation constant k_2. The incident plane wave propagates in the z axis direction and is as shown in FIG. **6**. The spherical coordinate system used for the vector spherical wave functions is shown in FIG. **7**. Expansion of the incident field provides:

$$E_i = E_o e^{-i\omega t} \sum_{n=1}^{\infty} i^n \frac{2n+1}{n(n+1)} \left(m^{(1)}_{01n} - i n^{(1)}_{eln}\right)$$

$$H_i = -\frac{k_2}{\omega\mu_2} E_o e^{-i\omega t} \sum_{n=1}^{\infty} i^n \frac{2n+1}{n(n+1)} \left(m^{(1)}_{eln} + i n^{(1)}_{01n}\right)$$

where E is the electric field and H is the magnetic field; and

$$m^{(1)}_{\substack{01n\\e1n}} = \pm \frac{1}{\sin\theta} j_n(k_2R) P_n^{1}(\cos\theta) \substack{\cos\\\sin} \phi i_2 - j_n(k_2R) \frac{\partial p_n^{1}}{\partial\theta} \substack{\sin\\\cos} \phi i_3$$

$$n^{(1)}_{\substack{0ln\\e1n}} = \frac{n(n+1)}{k_2R} j_n(k_2R) P_n^{1}(\cos\theta) \substack{\sin\\\cos} \phi i_1 + \frac{1}{k_2R} [k_2R j_n(k_2R)]' \times$$

$$\frac{\partial P_n^{1}}{\partial\theta} \substack{\sin\\\cos} \phi i_2 \pm \frac{1}{k_2R\sin\theta} [k_2R j_n(k_2R)]' P_n^{1}(\cos\theta) \substack{\cos\\\sin} \phi i_3.$$

The electric and magnetic fields of the incident wave transmitted into the sphere i.e., R<a, can be similarly expanded:

$$E_t = E_0 e^{-i\omega t} \sum_{n=1}^{\infty} i^n \frac{2n+1}{n(n+1)} \left(a_n^{t} m^{(1)}_{01n} - i b_n^{t} n^{(1)}_{e1n} \right)$$

$$H_t = \frac{k_2}{\phi\mu_1} E_0 e^{-i\omega t} \sum_{n=1}^{\infty} i^m \frac{2n+1}{n(n+1)} \left(b_n^{t} m^{(1)}_{e1n} - i a_n^{t} n^{(1)}_{01n} \right)$$

If $j_n(k_2R)$ is replaced by $h_n^{(1)}(k_2R)$ in the previous equations, the functions $m^{(1)}$ and $n^{(1)}$ become $m^{(3)}$ and $n^{(3)}$. The outgoing fields i.e., R>a, are represented by:

$$E_R = E_0 e^{-i\omega t} \sum_{n=1}^{\infty} i^n \frac{2n+1}{n(n+1)} \left(a_n^{r} m^{(3)}_{01n} - i b_n^{r} n^{(3)}_{e1n} \right)$$

$$H_r = \frac{k_2}{\phi\mu_1} E_0 e^{-i\omega t} \sum_{n=1}^{\infty} i^m \frac{2n+1}{n(n+1)} \left(b_n^{r} m^{(3)}_{e1n} - i a_n^{r} n^{(3)}_{01n} \right)$$

where H_r represents the resultant wave in the medium surrounding the sphere. At resonance, the values of ρ at resonance require that the a_n^t and b_n^t coefficients be infinite. In order to determine these values of a_n^t and b_n^t, the boundary conditions at the sphere radius are needed. Since there must be continuity of the E and H values at the surface, the following equations are used:

$$i_1 \times (E_i + E_r) = i_1 \times E_t \text{ and}$$

$$i_1 \times (H_i + H_r) = i_1 \times H_t$$

which lead to two pairs of inhomogeneous equations:

$$a_n^t j_n(N\rho) - a_n^r h_n^{(1)}(\rho) = j_n(\rho)$$

$$\mu_2 a_n^t [N\rho j_n(N\rho)]' - \mu_1 a_n^r [\rho h_n^{(1)}(\rho)]' = \mu_1 [\rho j_n(\rho)]' \text{ and}$$

$$\mu_2 N b_n^t j_n(N\rho) - \mu_1 b_n^r h_n^{(1)}(\rho) = \mu_1 j_n(\rho)$$

$$b_n^t [N\rho j_n(N\rho)]' - N b_n^r [\rho h_n^{(1)}(\rho)]' = N[\rho j_n(\rho)]'$$

where $k_1=Nk_2$, $\rho=k_2a$, $k_1a=N\rho$. Spherical Bessel functions of the first kind are denoted by j_n, while those of the third kind are denoted by $h_n^{(1)}$. The resulting equations are:

$$a_n^t = \frac{\mu_1 j_n(\rho)[\rho h_n^{(1)}(\rho)]' - \mu_1 h_n^{(1)}\rho)[\rho j_n(\rho)]'}{\mu_1 j_n(N\rho)[\rho h_n^{(1)}(\rho)]' - \mu_2 h_n^{(1)}(\rho)[N\rho j_n(N\rho)]'}$$

and

$$b_n^t = \frac{\mu_1 N j_n(\rho)[\rho h_n^{(1)}(\rho)]' - \mu_1 N h_n^{(1)}\rho)[\rho j_n(\rho)]'}{\mu_2 N^2 j_n(N\rho)[\rho h_n^{(1)}(\rho)]' - \mu_1 h_n^{(1)}(\rho)[N\rho j_n(N\rho)]'}$$

At a resonance, the denominator of either a_n^t or b_n^t will be zero. Thus, ρ values are found using the above equations that correspond to a resonant combination of angular frequency (ω) and radius (a) for a given sphere material and given surrounding medium. In determining such values of ρ, the following equations are also specifically used:

$$\rho = ak_2 = a\omega\sqrt{\epsilon_2\mu_2} \text{ and}$$

$$\rho_1 = (k_1/k_2)\rho$$

where ρ_1 corresponds to the sphere material. An iterative method is preferably used to find the desired values of ρ at resonance. In calculating ρ utilizing the above equations for purposes of example, it was assumed that $\mu_1=\mu_2=\mu_0=4\pi\times 10^{-7}$ and $\epsilon_2=\epsilon_0=8.85419\times10^{-12}$.

One major root of ρ which was found has a value of:

Real (ρ)=+66.39752607619131

Imaginary (ρ)=−0.6347867071968998.

These particular values are not shown in FIG. **8**. However, other values of ρ found using the equations set forth herein are shown in FIG. **8**. The peaks in FIG. **8** are the resonances. One of these resonances shown in FIG. **8** is shown in detail in FIG. **9**. These resonance values are shown for purposes of example. Other resonances also exist which have not been determined; thus, not all possible resonance values are shown in FIGS. **8** and **9**.

Calculation of these values also allows the determination of a possible am combination which would have these root values. For ρ, ϵ (epsilon)=ϵ_0 and $\mu=\mu_0$, and

$$\rho = a\omega\sqrt{\epsilon_0\mu_0} = a\omega/c.$$

Expressed in SI units, the speed of light $c=2.99792458\times10^{14}$ m/s. If an a value of 10^{-6} m is assumed for the examples shown herein, then:

$$\omega=\rho c/a\approx1.9919\times10^{16}-i1.9044\times10^{14}\text{ radians/s.}$$

This is an example of the angular frequency required within the impingent EM radiation in order to create a resonant situation. Examples of other resonances were indicated, and these are shown in FIG. **8**. No complex-frequency plane waves exist. Therefore, the calculations were made by considering only the real portion of the above root and setting the imaginary portion equal to zero. However, upon doing this, the iterative calculation procedure becomes insensitive to any root in the vicinity of the root's real portion. In the iterative calculation procedure, initially a range of ρ values is input into the equations. These ρ values are in the neighborhood of the prospective root. A range of ρ values is subsequently studied to find any imaginary ρ i.e., fρ (a function of ρ), peaks in that range. Next, once a peak has been chosen, the function order n giving the dominant fρ is determined. This also gives a clue as to whether the peak is due to a magnetic resonance (a_n approaches infinity) or an electrical resonance (b_n approaches infinity). A large number of Newton-Raphson iterations is preferably performed in order to converge upon a root ρ value.

FIGS. **2** and **3** show a second embodiment of the present invention generally designated by the numeral **110**. Embodiment **110** is essentially the same as embodiment **10** except that the antenna is a rf cavity structure **122** which feeds the received beat frequency radiation **124** to a waveguide **126**. Embodiment **110** also preferably includes two spheres **112** and **114** which receive the primary incident electromagnetic radiation **116** and emit the secondary electromagnetic radiation **118** and **120**. As with the spheres **18** and **20** of embodiment **10**, spheres **118** and **120** are preferably composed of a dielectric material. Embodiment **110** also includes converter **128**, capacitor **130**, transformer **132** and rectifier **134** which are essentially identical to the correspondingly numbered elements of embodiment **10**. Therefore, a description of these components of embodiment **110** will not be repeated in order to promote brevity. In addition, the same equations and method of calculation set forth above with regard to embodiment **10** also apply to embodiment. Therefore, their description will not be repeated in order to promote brevity.

FIGS. **4** and **5** show a third embodiment of the present invention generally designated by numeral **210**. Embodiment **210** is essentially identical to the first embodiment **10** except that the embodiment **210** includes a plurality of pairs **215** of receiving means (spheres) **212** and **214** mounted on a substrate **236**. The spheres **212** and **214** are thus in the form of an array **238**. The pairs **215** of the array **238** are preferably positioned proximal to each other in order to maximize the amount of energy extracted from a particular area or space of a given size. Since, as set forth hereinabove, the energy density of the zero point radiation increases as the frequency of the radiation increases, it is desirable that the spheres resonate at as high a bandwidth of frequencies as possible. Because the spheres **212** and **214** must be small in direct proportion to the wavelength of the high frequencies of the incident electromagnetic radiation **216** at which resonance is desirably obtained, the spheres **212** and **214** are preferably microscopic in size. Current lithographic techniques are capable of manufacturing such microscopically small spheres mounted on a suitable substrate thereby providing a suitably miniaturized system **210**. A miniaturized system enhances the energy output capability of the system by enabling it to resonate at higher frequencies at which there are correspondingly higher energy densities. Consequently, utilization of array **238** in the system **210** enhances the maximum amount of electrical energy provided by the system **210**.

Lithographic techniques may be more amenable to manufacturing microscopically small receiving structures **212** and **214** which may be disc shaped, semispherical or have another shape other than as shown in FIGS. **4** and **5**. Consequently, the receiving means **212** and **214** may accordingly have such alternative shapes rather than the spherical shape shown in FIGS. **4** and **5**. In addition, a large number of small spheres may be manufactured by bulk chemical reactions. Packing a volume with such spheres in close proximity could enhance the output of energy.

Embodiment **210** also includes a plurality of antennas **222** positioned preferably between the spheres **212** and **214** which receive the beat frequency radiation **224** produced by the interference between the secondary radiation **218** and **220**. The antennas **222** are shown as loop antennas **222** but may be any other suitable type of antennas as well.

Embodiment **210** has a plurality of electrical conductors **226** which preferably include traces mounted on the substrate **236** which occupies a finite volume. The electrical conductors **226** feed the electrical output from the antennas **222** to a suitable converter **228** which preferably includes tuning capacitor **230**, transformer **232** and rectifier **234**, as with embodiments **10** and **110**. Except as set forth above, the components of embodiment **210** are identical to embodiment **10** so the detailed description of these components will not be repeated in order to promote brevity. In addition, the same equations and method of calculation set forth above for embodiment **10** also apply to embodiment **210**. Therefore, the description of these equations and method of calculation will not be repeated in order to promote brevity.

Accordingly, there has been provided, in accordance with the invention, a system which converts high frequency zero point electromagnetic radiation into electrical energy effectively and efficiently and thus fully satisfies the objectives set forth above. It is to be understood that all terms used herein are descriptive rather than limiting. Although the invention has been specifically described with regard to the specific embodiments set forth herein, many alternative embodiments, modifications and variations will be apparent to those skilled in the art in light of the disclosure set forth herein. Accordingly, it is intended to include all such alternatives, embodiments, modifications and variations that fall within the spirit and scope of the invention as set forth in the claims hereinbelow.

What is claimed is:

1. A system for converting incident electromagnetic radiation energy to electrical energy, comprising:

a first means for receiving incident primary electromagnetic radiation, said means for receiving producing emitted secondary electromagnetic radiation at a first frequency, said first means for receiving having a first volumetric size selected to resonate at a frequency within the frequency spectrum of the incident primary electromagnetic radiation in order to produce the secondary electromagnetic radiation at the first frequency at an enhanced energy density;

a second means for receiving the incident primary electromagnetic radiation, said means for receiving producing emitted secondary electromagnetic radiation at a second frequency, the secondary radiation at the first frequency and the secondary radiation at the second frequency interfering to produce secondary radiation at a lower frequency than that of the incident primary radiation, said second means for receiving having a second volumetric size selected to resonate at a frequency within the frequency spectrum of the incident primary electromagnetic radiation in order to produce the emitted secondary electromagnetic radiation at the second frequency at an enhanced energy density;

an antenna for receiving the emitted secondary electromagnetic radiation at the lower frequency, said antenna providing an electrical output responsive to the secondary electromagnetic radiation received;

a converter electrically connected to said antenna for receiving electrical current output from said antenna and converting the electrical current output to electrical current having a desired voltage and waveform.

2. The system of claim **1** wherein:

said first means for receiving is composed of a dielectric material; and

said second means for receiving is composed of a dielectric material.

3. The system of claim **1** wherein:

said first means for receiving is spherical; and

said second means for receiving is spherical.

4. A system for for converting incident zero point electromagnetic radiation energy to electrical energy, comprising:

a first means for receiving incident primary zero point electromagnetic radiation, said means for receiving producing emitted secondary electromagnetic radiation at a first frequency;

a second means for receiving the incident primary zero point electromagnetic radiation, said means for receiving producing emitted secondary electromagnetic radiation at a second frequency, the secondary radiation at the first frequency and the secondary radiation at the second frequency interfering to produce secondary radiation at a beat frequency which is lower than that of the incident primary radiation;

an antenna for receiving the emitted secondary electromagnetic radiation at the lower frequency, said antenna providing an electrical output responsive to the secondary electromagnetic radiation received;

means for transmitting the emitted secondary electromagnetic radiation at the beat frequency from said antenna, said means for transmitting connected to said antenna;

a converter connected to said means for transmitting for receiving the emitted secondary electromagnetic radiation at the beat frequency from said antenna and converting the same to electrical current having a desired voltage and waveform.

5. The system of claim **4** wherein:

said first means for receiving has a first volumetric spherical size selected to resonate in response to the incident primary electromagnetic radiation in order to produce the secondary electromagnetic radiation at the first frequency at an enhanced energy density; and

said second means for receiving has a second volumetric spherical size selected to resonate in response to the incident primary electromagnetic radiation in order to produce the emitted secondary electromagnetic radiation at the second frequency at an enhanced energy density, said first and second volumetric sizes selected based on parameters of propagation constant of said first and second means for receiving, propagation constant of medium in which said first and second means for receiving are located and frequency of the incident primary electromagnetic radiation.

6. The system of claim **5** wherein the first and second volumetric sizes are selected by utilizing the formulas:

$$a_n{}^{t}=\frac{\mu_1 j_n(\rho)[\rho h_n^{(1)}(\rho)]'-\mu_1 h_n^{(1)}\rho)[\rho j_n(\rho)]'}{\mu_1 j_n(N\rho)[\rho h_n^{(1)}(\rho)]'-\mu_2 h_n^{(1)}(\rho)[N\rho j_n(N\rho)]'}$$

$$b_n{}^{t}=\frac{\mu_1 N j_n(\rho)[\rho h_n^{(1)}(\rho)]'-\mu_1 N h_n^{(1)}\rho)[\rho j_n(\rho)]'}{\mu_2 N^2 j_n(N\rho)[\rho h_n^{(1)}(\rho)]'-\mu_1 h_n^{(1)}(\rho)[N\rho j_n(N\rho)]'}$$

$$\rho=a\omega\sqrt{\epsilon_2\mu_2}$$

wherein at a resonance, the denominator of either equation for $a_n{}^{t}$ or $b_n{}^{t}$ will be approximately zero and wherein k_1=propagation constant of the means for receiving, k_2=propagation constant of medium through which the incident electromagnetic radiation propagates, a is the radius of either means for receiving, $N=k_1/k_2$, $\rho=k_2a$, $k_1a=N\rho$, $a_n{}^{t}$=magnitude of oscillations of the electric field of the nth order, $b_n{}^{t}$=magnitude of oscillations of the magnetic field of the nth order, ω=angular frequency of the incident electromagnetic radiation, ϵ is the permittivity of the material or medium and μ is the permeability of the material or medium.

7. The system of claim **6** wherein the radius of the first means for receiving is different from the radius of the second means for receiving, difference between the radius of said first means for receiving and the radius of said second means for receiving selected so that the beat frequency resulting from the difference is a frequency which facilitates conversion of the beat frequency electromagnetic radiation to electrical energy.

8. The system of claim **4** wherein:

said first means for receiving is composed of a dielectric material; and

said second means for receiving is composed of a dielectric material.

9. The system of claim **4** wherein:

said first means for receiving is spherical; and

said second means for receiving is spherical.

10. The system of claim **4** wherein said antenna is positioned generally between said first and second means for receiving.

11. The system of claim **4** wherein said antenna is a loop antenna.

12. The system of claim **4** wherein said antenna is a generally concave shell partially enclosing said first and second means for receiving.

13. The system of claim **4** wherein said means for transmitting is a waveguide.

14. A system for for converting incident zero point electromagnetic radiation energy to electrical energy, comprising:

a substrate;

a plurality of pairs of first means for receiving incident primary zero point electromagnetic radiation and second means for receiving incident primary zero point electromagnetic radiation, said plurality of pairs of means for receiving mounted on said substrate, said first means for receiving producing emitted secondary

electromagnetic radiation at a first frequency, said second means for receiving the incident primary zero point electromagnetic radiation producing emitted secondary electromagnetic radiation at a second frequency, the secondary radiation at the first frequency and the secondary radiation at the second frequency interfering to produce secondary radiation at a beat frequency which is lower than that of the incident primary radiation, said first means for receiving having a first volumetric size selected to resonate in response to the incident primary electromagnetic radiation in order to produce the secondary electromagnetic radiation at the first frequency at an enhanced energy density, and said second means for receiving having a second volumetric size selected to resonate in response to the incident primary electromagnetic radiation in order to produce the emitted secondary electromagnetic radiation at the second frequency at an enhanced energy density, said first and second volumetric sizes selected based on parameters of propagation constant of said first and second means for receiving, propagation constant of medium in which said first and second means for receiving are located and frequency of the incident primary electromagnetic radiation, said first and second volumetric sizes being different from each other;

a plurality of antennas for receiving the emitted secondary electromagnetic radiation at the lower frequency, said antenna providing an output responsive to the secondary electromagnetic radiation received, said plurality of antennas mounted on said substrate, each of said plurality of antennas receiving the emitted secondary electromagnetic radiation of one of said pairs of first and second means for receiving;

means for transmitting the emitted secondary electromagnetic radiation at the beat frequency from said antenna, said means for transmitting connected to said plurality of antennas;

a converter connected to said means for transmitting for receiving the emitted secondary electromagnetic radiation at the beat frequency from said antenna and converting the same to electrical current having a desired voltage and waveform.

In electronics, a diode is a two-terminal electronic component that conducts primarily in one direction; it has low resistance to the flow of current in one direction, and high resistance in the other. A semiconductor diode, the most common type today, is a crystalline piece of semiconductor material with a p–n junction connected to two electrical terminals. A vacuum tube diode has two electrodes, a plate and a heated cathode. Semiconductor diodes were the first semiconductor electronic devices. The discovery of crystals' rectifying abilities was made by German physicist Ferdinand Braun in 1874. The first semiconductor diodes, called cat's whisker diodes, developed around 1906, were made of mineral crystals such as galena. Today, most diodes are made of silicon, but other semiconductors such as selenium or germanium are sometimes used.

This diode is able to detect RF signals and converts it to DC electricity to power a Led the amazing thing about this is that its completely passive and doesn't require any batteries... Gold Plated Slug 1N23B is Vintage U.S. ARMY Military for General Purpose UHF-MW Silicon Mixer. Primarily used in the Allies’ radar systems during World War II.

GENERATORS, HIGH ALTITUDE DISCHARGES, TLE’s

PHYSICAL PROCESSES

TLE’s (Sprites, Blue Jets, Elves, Gigantic jets) are electrical discharges in the stratosphere and mesosphere above active thunderstorm clouds

Sprites

Large Electric Field between cloud and ionosphere following a +CG

Break-down threshold reached at ~ 70 km

Elves

Initiated from the EMP following a CG

Ionization and luminous halo produced in the mesosphere at ~ 90 km

Blue Jets and Gigantic Jets

Streamer initiated at cloud top (~ 15-18 km) by localized intensification of the electric field

Propagate up to ~40 km for BJ, ~ 70 km or GJ

ACCELERATION PROCESSES, TGF

PHYSICAL PROCESSES

Acceleration of Electrons up to ~ 100 MeV

- **Relativistic Runaway Electron Avalanche from cosmic ray generated electrons initially proposed. But**
  (i) cosmic ray showers not a sufficient electron source
  (ii) RREA cannot account for the intensity of TGF fluxes.

-**Two mechanisms recently proposed (Dwyer2007, 2008):**
  - **Relativistic Feedback mechanism from backward propagating positrons and scattered X,γ rays**
- **Runaway Electron production in large E-fields reproduces the duration and intensity of TGF**

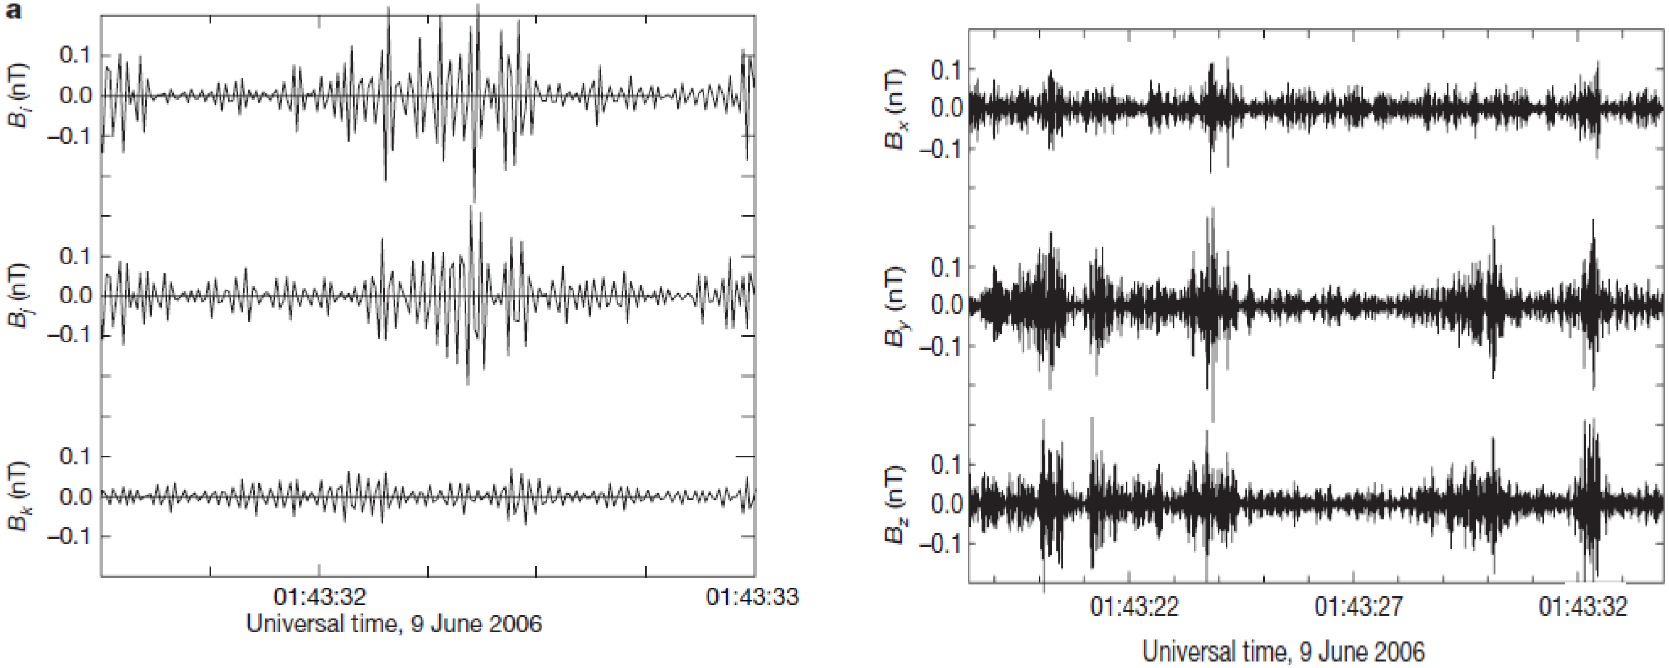
PLANETARY ATMOSPHERIC ELECTRICITY

CONDITIONS FOR A GLOBAL ELECTRICAL CIRCUIT ON OTHER PLANETS

	Ion mobility in lower atmosphere	Upper Conductive Boundary	Lower Conductive Boundary	Clouds	Electrification Mechanisms
Venus	yes	Ionosphere	Yes σ_g small	yes	Charge separation Lightning
Mars	yes	Ionosphere	σ_g? Water reservoirs?	Faint, high altitude	Dust impact
Jupiter	Probably not in deep atmosphere	Ionosphere	? Deep layers?	yes	Charge separation lightning
Saturn	Probably not in deep atmosphere	Ionosphere	? Deep layers?	yes	Charge separation Lightning
Titan	Yes, weak at low altitude	Ionosphere	Buried ocean	yes	? Lightning not observed

VENUS



Whistler mode ELF signals from the Venus Express magnetometer
Indicating the existence of lightning

Russel et al., ASR 2008

MARS

Conductivity

- profile similar to Earth
- σ at surface ~ 10^3 σ on Earth

Electrification Mechanism

- Dust Impact
- Charge depends on size, material
- Breakdown at ~ 10 kV/m

Generators

- Dust storms
- Dust Devils

Observations

-SR of extremely high amplitude (?)

EM emissions from lightning

SATURN and JUPITER

Comparison between Saturn, Jupiter and Earth lightning

Lightning sources :

- Saturn: Giant convective storm systems 3000 km in diameter, equator or 35°S
- Jupiter: numerous storms in ~ 5° latitude bands at ~ 50° N and S
- Updrafting water clouds at levels of ~ 10 bar (Saturn), ~ 5 bar (Jupiter)

Characteristics

- Frequency spectrum: up to 20 MHz / a few kHz / a few MHz
- Spectral power at MHz frequencies 100 W/Hz / ~10 / 0.01

Physical process

- Saturn: Elves more likely than Sprites
- Jupiter: lightning a few ms long

Desch et al., 2002; Fisher et al., 2008

TITAN

36 Hz peak in ELF AC electric field spectrum
interpreted as the second harmonic of Schumann resonnance
of the planet-ionosphere wave-guide due to a buried ocean at ~ 60-80 km depth

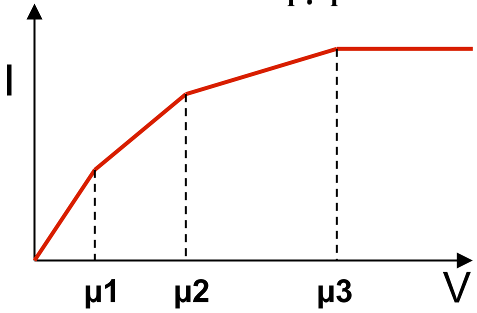
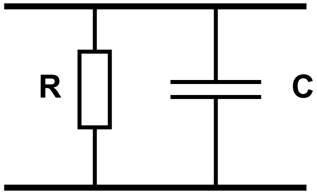
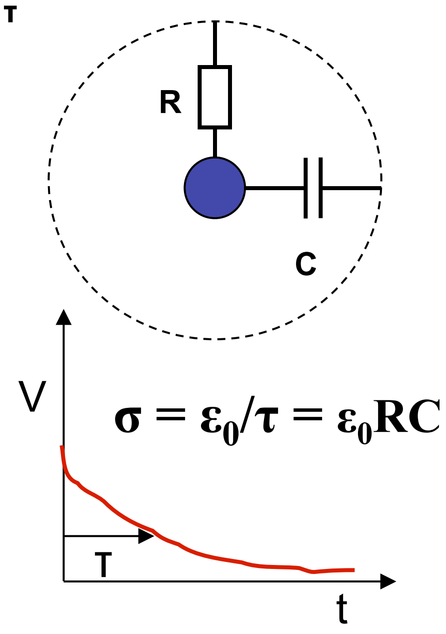
i+ μ>μc
i+ μ=μc

$\sigma^+ = \Sigma\ e.n_i.\mu_i$



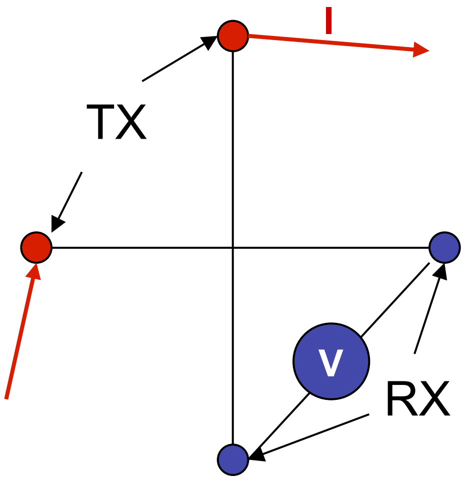
Relaxation method

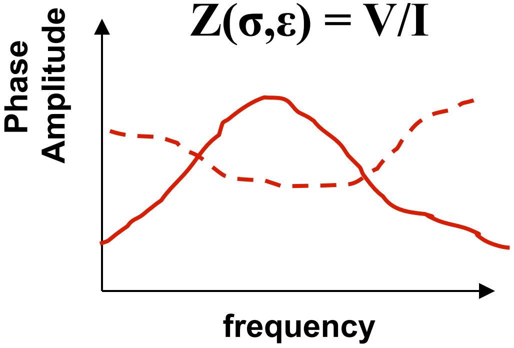




$\sigma = \varepsilon_0/\tau = \varepsilon_0 RC$

Mutual Impedance





$Z(\sigma,\varepsilon) = V/I$

ATMOSPHERE ELECTRIC CONDUCTIVITY (2)

Gerdien condenser

- gives access to the ion mobility spectrum
- relaxation method can be included
- requires accurately controlled air flow
- complexity (fan, electronics…)

Relaxation method (with electrostatic probes)

- simple, can be easily implemented on double probe
- accurate technique for large enough σ and stable electric field
- analysis difficult with a variable background electric field
- requires specific modeling in case of space charge

Mutual impedance

- accurate in atmospheres with both ions and electrons
- able to provide soil measurements if landed on planetary surface
- complexity (booms, electronics…)

HF : cylindrical long antenna

ELECTRIC FIELD MEASUREMENTS

INDUCTIVE COUPLING, THE « FIELD MACHINES »

- high impedance, can operate in very low σ (Earth's surface)
- can measure large DC electric fields
- Some directional capability, 2D measurement with 1 sensor
- innovative designs in progress, miniaturized devices, vibrating system, ASIC

- low sensitivity
- electro-mechanical device (harsh environments, dust, EMI…), signal processing
- low temporal resolution and low frequency capability (no waves)

RESISTIVE COUPLING, THE DOUBLE PROBE INSTRUMENT

- simple device and electronics
- high sensitivity (in AC better than $1\mu V/mHz^{1/2}$)
- high temporal resolution (lightning), high frequency capability (MHz)
- direct measurement, no signal processing
- high amplitude DC and AC electric field measurements in dedicated modes

- booms (deployment, mass,…)
- limited to $\sigma \geq 10^{-13}$ S/m (on Earth above ~ 8 kilometers)

THE HASI/PWA EXPERIMENT ON HUYGENS

PWA aimed at contributing to answering the following questions:

- What are the ion and electron conductivity profiles?
- What is the role of aerosols in atmospheric chemistry?
- Is there lightning on Titan?
- Do standing waves form in the surface-ionosphere cavity?
- What are the dielectric properties of the surface?
- Does a global electric circuit exist on Titan?

[57] **ABSTRACT**

A method and apparatus for altering at least one selected region which normally exists above the earth's surface. The region is excited by electron cyclotron resonance heating to thereby increase its charged particle density. In one embodiment, circularly polarized electromagnetic radiation is transmitted upward in a direction substantially parallel to and along a field line which extends through the region of plasma to be altered. The radiation is transmitted at a frequency which excites electron cyclotron resonance to heat and accelerate the charged particles. This increase in energy can cause ionization of neutral particles which are then absorbed as part of the region thereby increasing the charged particle density of the region.

FIG. 5

METHOD AND APPARATUS FOR ALTERING A REGION IN THE EARTH'S ATMOSPHERE, IONOSPHERE, AND/OR MAGNETOSPHERE

DESCRIPTION

1. Technical Field

This invention relates to a method and apparatus for altering at least one selected region normally existing above the earth's surface and more particularly relates to a method and apparatus for altering said at least one region by initially transmitting electromagnetic radiation from the earth's surface essentially parallel to and along naturally-occurring, divergent magnetic field lines which extend from the earth's surface through the region or regions to be altered.

2. Background Art

In the late 1950's, it was discovered that naturally-occuring belts exist at high altitudes above the earth's surface, and it is now established that these belts result from charged electrons and ions becoming trapped along the magnetic lines of force (field lines) of the earth's essentially dipole magnetic field. The trapped electrons and ions are confined along the field lines between two magnetic mirrors which exist at spaced apart points along those field lines. The trapped electrons and ions move in helical paths around their particular field lines and "bounce" back and forth between the magnetic mirrors. These trapped electrons and ions can oscillate along the field lines for long periods of time.

In the past several years, substantial effort has been made to understand and explain the phenomena involved in belts of trapped electrons and ions, and to explore possible ways to control and use these phenomena for beneficial purposes. For example, in the late 1950's and early 1960's both the United States and U.S.S.R. detonated a series of nuclear devices of various yields to generate large numbers of charged particles at various altitudes, e.g., 200 kilometers (km) or greater. This was done in order to establish and study artifical belts of trapped electrons and ions. These experiments established that at least some of the extraneous electrons and ions from the detonated devices did become trapped along field lines in the earth's magnetosphere to form artificial belts which were stable for prolonged periods of time. For a discussion of these experiments see "The Radiation Belt and Magnetosphere", W. N. Hess, Blaisdell Publishing Co., 1968, pps. 155 et sec.

Other proposals which have been advanced for altering existing belts of trapped electrons and ions and/or establishing similar artificial belts include injecting charged particles from a satellite carrying a payload of radioactive beta-decay material or alpha emitters; and injecting charged particles from a satellite-borne electron accelerator. Still another approach is described in U.S. Pat. No. 4,042,196 wherein a low energy ionized gas, e.g., hydrogen, is released from a synchronous orbiting satellite near the apex of a radiation belt which is naturally-occurring in the earth's magnetosphere to produce a substantial increase in energetic particle precipitation and, under certain conditions, produce a limit in the number of particles that can be stably trapped. This precipitation effect arises from an enhancement of the whistler-mode and ion-cyclotron mode interactions that result from the ionized gas or "cold plasma" injection.

It has also been proposed to release large clouds of barium in the magnetosphere so that photoionization will increase the cold plasma density, thereby producing electron precipitation through enhanced whistler-mode interactions.

However, in all of the above-mentioned approaches, the mechanisms involved in triggering the change in the trapped particle phenomena must be actually positioned within the affected zone, e.g., the magnetosphere, before they can be actuated to effect the desired change.

The earth's ionosphere is not considered to be a "trapped" belt since there are few trapped particles therein. The term "trapped" herein refers to situations where the force of gravity on the trapped particles is balanced by magnetic forces rather than hydrostatic or collisional forces. The charged electrons and ions in the ionosphere also follow helical paths around magnetic field lines within the ionosphere but are not trapped between mirrors, as in the case of the trapped belts in the magnetosphere, since the gravitational force on the particles is balanced by collisional or hydrostatic forces.

In recent years, a number of experiments have actually been carried out to modify the ionosphere in some controlled manner to investigate the possibility of a beneficial result. For detailed discussions of these operations see the following papers: (1) Ionospheric Modification Theory; G. Meltz and F. W. Perkins; (2) The Platteville High Power Facility; Carrol et al.; (3) Arecibo Heating Experiments; W. E. Gordon and H. C. Carlson, Jr.; and (4) Ionospheric Heating by Powerful Radio Waves; Meltz et al., all published in Radio Science, Vol. 9, No. 11, November, 1974, at pages 885–888; 889–894; 1041–1047; and 1049–1063, respectively, all of which are incorporated herein by reference. In such experiments, certain regions of the ionosphere are heated to change the electron density and temperature within these regions. This is accomplished by transmitting from earth-based antennae high frequency electromagnetic radiation at a substantial angle to, not parallel to, the ionosphere's magnetic field to heat the ionospheric particles primarily by ohmic heating. The electron temperature of the ionosphere has been raised by hundreds of degrees in these experiments, and electrons with several electron volts of energy have been produced in numbers sufficient to enhance airglow. Electron concentrations have been reduced by a few percent, due to expansion of the plasma as a result of increased temperature.

In the Elmo Bumpy Torus (EBT), a controlled fusion device at the Oak Ridge National Laboratory, all heating is provided by microwaves at the electron cyclotron resonance interaction. A ring of hot electrons is formed at the earth's surface in the magnetic mirror by a combination of electron cyclotron resonance and stochastic heating. In the EBT, the ring electrons are produced with an average "temperature" of 250 kilo electron volts or kev (2.5×10^9K) and a plasma beta between 0.1 and 0.4; see, "A Theoretical Study of Electron—Cyclotron Absorption in Elmo Bumpy Torus", Batchelor and Goldfinger, Nuclear Fusion, Vol. 20, No. 4 (1980) pps. 403–418.

Electron cyclotron resonance heating has been used in experiments on the earth's surface to produce and accelerate plasmas in a diverging magnetic field. Kosmahl et al. showed that power was transferred from the electromagnetic waves and that a fully ionized plasma

was accelerated with a divergence angle of roughly 13 degrees. Optimum neutral gas density was 1.7×10^{14}per cubic centimeter; see, "Plasma Acceleration with Microwaves Near Cyclotron Resonance", Kosmahl et al., Journal of Applied Physics, Vol. 38, No. 12, Nov., 1967, pps. 4576–4582.

DISCLOSURE OF THE INVENTION

The present invention provides a method and apparatus for altering at least one selected region which normally exists above the earth's surface. The region is excited by electron cyclotron resonance heating of electrons which are already present and/or artifically created in the region to thereby increase the charged particle energy and ultimately the density of the region.

In one embodiment this is done by transmitting circularly polarized electromagnetic radiation from the earth's surface at or near the location where a naturally-occurring dipole magnetic field (force) line intersects the earth's surface. Right hand circular polarization is used in the northern hemisphere and left hand circular polarization is used in the southern hemisphere. The radiation is deliberately transmitted at the outset in a direction substantially parallel to and along a field line which extends upwardly through the region to be altered. The radiation is transmitted at a frequency which is based on the gyrofrequency of the charged particles and which, when applied to the at least one region, excites electron cyclotron resonance within the region or regions to heat and accelerate the charged particles in their respective helical paths around and along the field line. Sufficient energy is employed to cause ionization of neutral particles (molecules of oxygen, nitrogen and the like, particulates, etc.) which then become a part of the region thereby increasing the charged particle density of the region. This effect can further be enhanced by providing artificial particles, e.g., electrons, ions, etc., directly into the region to be affected from a rocket, satellite, or the like to supplement the particles in the naturally-occurring plasma. These artificial particles are also ionized by the transmitted electromagnetic radiation thereby increasing charged particle density of the resulting plasma in the region.

In another embodiment of the invention, electron cyclotron resonance heating is carried out in the selected region or regions at sufficient power levels to allow a plasma present in the region to generate a mirror force which forces the charged electrons of the altered plasma upward along the force line to an altitude which is higher than the original altitude. In this case the relevant mirror points are at the base of the altered region or regions. The charged electrons drag ions with them as well as other particles that may be present. Sufficient power, e.g., 10^{15}joules, can be applied so that the altered plasma can be trapped on the field line between mirror points and will oscillate in space for prolonged periods of time. By this embodiment, a plume of altered plasma can be established at selected locations for communication modification or other purposes.

In another embodiment, this invention is used to alter at least one selected region of plasma in the ionosphere to establish a defined layer of plasma having an increased charged particle density. Once this layer is established, and while maintaining the transmission of the main beam of circularly polarized electromagnetic radiation, the main beam is modulated and/or at least one second different, modulated electromagnetic radiation beam is transmitted from at least one separate source at a different frequency which will be absorbed in the plasma layer. The amplitude of the frequency of the main beam and/or the second beam or beams is modulated in resonance with at least one known oscillation mode in the selected region or regions to excite the known oscillation mode to propagate a known frequency wave or waves throughout the ionosphere.

BRIEF DESCRIPTION OF THE DRAWINGS

The actual construction, operation, and apparent advantages of this invention will be better understood by referring to the drawings in which like numerals identify like parts and in which:

FIG. **1** is a simplified schematical view of the earth (not to scale) with a magnetic field (force) line along which the present invention is carried out;

FIG. **2** is one embodiment within the present invention in which a selected region of plasma is raised to a higher altitude;

FIG. **3** is a simplified, idealized representation of a physical phenomenon involved in the present invention; and

FIG. **4** is a schematic view of another embodiment within the present invention.

FIG. **5** is a schematic view of an apparatus embodiment within this invention.

BEST MODES FOR CARRYING OUT THE INVENTION

The earth's magnetic field is somewhat analogous to a dipole bar magnet. As such, the earth's magnetic field contains numerous divergent field or force lines, each line intersecting the earth's surface at points on opposite sides of the Equator. The field lines which intersect the earth's surface near the poles have apexes which lie at the furthest points in the earth's magnetosphere while those closest to the Equator have apexes which reach only the lower portion of the magnetosphere.

At various altitudes above the earth's surface, e.g., in both the ionosphere and the magnetosphere, plasma is naturally present along these field lines. This plasma consists of equal numbers of positively and negatively charged particles (i.e., electrons and ions) which are guided by the field line. It is well established that a charged particle in a magnetic field gyrates about field lines, the center of gyration at any instance being called the "guiding center" of the particle. As the gyrating particle moves along a field line in a uniform field, it will follow a helical path about its guiding center, hence linear motion, and will remain on the field line. Electrons and ions both follow helical paths around a field line but rotate in opposite directions. The frequencies at which the electrons and ions rotate about the field line are called gyromagnetic frequencies or cyclotron frequencies because they are identical with the expression for the angular frequencies of gyration of particles in a cyclotron. The cyclotron frequency of ions in a given magnetic field is less than that of electrons, in inverse proportion to their masses.

If the particles which form the plasma along the earth's field lines continued to move with a constant pitch angle, often designated "alpha", they would soon impact on the earth's surface. Pitch angle alpha is defined as the angle between the direction of the earth's magnetic field and the velocity (V) of the particle. However, in converging force fields, the pitch angle does change in such a way as to allow the particle to

turn around and avoid impact. Consider a particle moving along a field line down toward the earth. It moves into a region of increasing magnetic field strength and therefore sine alpha increases. But sine alpha can only increase to 1.0, at which point, the particle turns around and starts moving up along the field line, and alpha decreases. The point at which the particle turns around is called the mirror point, and there alpha equals ninety degrees. This process is repeated at the other end of the field line where the same magnetic field strength value B, namely Bm, exists. The particle again turns around and this is called the "conjugate point" of the original mirror point. The particle is therefore trapped and bounces between the two magnetic mirrors. The particle can continue oscillating in space in this manner for long periods of time. The actual place where a particle will mirror can be calculated from the following:

$$\sin^2 \text{alpha}_o = B_o/B_m \qquad (1)$$

wherein:

alpha_o = equatorial pitch angle of particle

B_o = equatorial field strength on a particular field line

B_m = field strength at the mirror point

Recent discoveries have established that there are substantial regions of naturally trapped particles in space which are commonly called "trapped radiation belts". These belts occur at altitudes greater than about 500 km and accordingly lie in the magnetosphere and mostly above the ionosphere.

The ionosphere, while it may overlap some of the trapped-particle belts, is a region in which hydrostatic forces govern its particle distribution in the gravitational field. Particle motion within the ionosphere is governed by both hydrodynamic and electrodynamic forces. While there are few trapped particles in the ionosphere, nevertheless, plasma is present along field lines in the ionosphere. The charged particles which form this plasma move between collisions with other particles along similar helical paths around the field lines and although a particular particle may diffuse downward into the earth's lower atmosphere or lose energy and diverge from its original field line due to collisions with other particles, these charged particles are normally replaced by other available charged particles or by particles that are ionized by collision with said particle. The electron density (N_e) of the plasma will vary with the actual conditions and locations involved. Also, neutral particles, ions, and electrons are present in proximity to the field lines.

The production of enhanced ionization will also alter the distribution of atomic and molecular constituents of the atmosphere, most notably through increased atomic nitrogen concentration. The upper atmosphere is normally rich in atomic oxygen (the dominant atmospheric constituent above 200 km altitude), but atomic nitrogen is normally relatively rare. This can be expected to manifest itself in increased airglow, among other effects.

As known in plasma physics, the characteristics of a plasma can be altered by adding energy to the charged particles or by ionizing or exciting additional particles to increase the density of the plasma. One way to do this is by heating the plasma which can be accomplished in different ways, e.g., ohmic, magnetic compression, shock waves, magnetic pumping, electron cyclotron resonance, and the like.

Since electron cyclotron resonance heating is involved in the present invention, a brief discussion of

same is in order. Increasing the energy of electrons in a plasma by invoking electron cyclotron resonance heating, is based on a principle similar to that utilized to accelerate charged particles in a cyclotron. If a plasma is confined by a static axial magnetic field of strength B, the charged particles will gyrate about the lines of force with a frequency given, in hertz, as $f_g = 1.54 \times 10^3 B/A$, where: B = magnetic field strength in gauss, and A = mass number of the ion.

Suppose a time-varying field of this frequency is superimposed on the static field B confining the plasma, by passage of a radiofrequency current through a coil which is concentric with that producing the axial field, then in each half-cycle of their rotation about the field lines, the charged particles acquire energy from the oscillating electric field associated with the radio frequency. For example, if B is 10,000 gauss, the frequency of the field which is in resonance with protons in a plasma is 15.4 megahertz.

As applied to electrons, electron cyclotron resonance heating requires an oscillating field having a definite frequency determined by the strength of the confining field. The radio-frequency radiation produces time-varying fields (electric and magnetic), and the electric field accelerates the charged particle. The energized electrons share their energy with ions and neutrals by undergoing collisions with these particles, thereby effectively raising the temperature of the electrons, ions, and neutrals. The apportionment of energy among these species is determined by collision frequencies. For a more detailed understanding of the physics involved, see "Controlled Thermonuclear Reactions", Glasstone and Lovberg, D. Van Nostrand Company, Inc., Princeton, N.J., 1960 and "The Radiation Belt and Magnetosphere", Hess, Blaisdell Publishing Company, 1968, both of which are incorporated herein by reference.

Referring now to the drawings, the present invention provides a method and apparatus for altering at least one region of plasma which lies along a field line, particularly when it passes through the ionosphere and/or magnetosphere. FIG. **1** is a simplified illustration of the earth **10** and one of its dipole magnetic force or field lines **11**. As will be understood, line **11** may be any one of the numerous naturally existing field lines and the actual geographical locations **13** and **14** of line **11** will be chosen based on a particular operation to be carried out. The actual locations at which field lines intersect the earth's surface is documented and is readily ascertainable by those skilled in the art.

Line **11** passes through region R which lies at an altitude above the earth's surface. A wide range of altitudes are useful given the power that can be employed by the practice of this invention. The electron cyclotron resonance heating effect can be made to act on electrons anywhere above the surface of the earth. These electrons may be already present in the atmosphere, ionosphere, and/or magnetosphere of the earth, or can be artificially generated by a variety of means such as x-ray beams, charged particle beams, lasers, the plasma sheath surrounding an object such as a missile or meteor, and the like. Further, artificial particles, e.g., electrons, ions, etc., can be injected directly into region R from an earth-launched rocket or orbiting satellite carrying, for example, a payload of radioactive beta-decay material; alpha emitters; an electron accelerator; and/or ionized gases such as hydrogen; see U.S. Pat. No. 4,042,196. The altitude can be greater than about 50 km if desired,

e.g., can be from about 50 km to about 800 km, and, accordingly may lie in either the ionosphere or the magnetosphere or both. As explained above, plasma will be present along line **11** within region R and is represented by the helical line **12**. Plasma **12** is comprised of charged particles (i.e., electrons and ions) which rotate about opposing helical paths along line **11**.

Antenna **15** is positioned as close as is practical to the location **14** where line **11** intersects the earth's surface. Antenna **15** may be of any known construction for high directionality, for example, a phased array, beam spread angle (θ) type. See "The MST Radar at Poker Flat, Alaska", Radio Science, Vol. 15, No. 2, Mar.-Apr. 1980, pps. 213–223, which is incorporated herein by reference. Antenna **15** is coupled to transmitter **16** which generates a beam of high frequency electromagnetic radiation at a wide range of discrete frequencies, e.g., from about 20 to about 1800 kilohertz (kHz).

Transmitter **16** is powered by power generator means **17** which is preferably comprised of one or more large, commercial electrical generators. Some embodiments of the present invention require large amounts of power, e.g., up to 10^9 to 10^{11} watts, in continuous wave or pulsed power. Generation of the needed power is within the state of the art. Although the electrical generators necessary for the practice of the invention can be powered in any known manner, for example, by nuclear reactors, hydroelectric facilities, hydrocarbon fuels, and the like, this invention, because of its very large power requirement in certain applications, is particularly adapted for use with certain types of fuel sources which naturally occur at strategic geographical locations around the earth. For example, large reserves of hydrocarbons (oil and natural gas) exist in Alaska and Canada. In northern Alaska, particularly the North Slope region, large reserves are currently readily available. Alaska and northern Canada also are ideally located geographically as to magnetic latitudes. Alaska provides easy access to magnetic field lines that are especially suited to the practice of this invention, since many field lines which extend to desirable altitudes for this invention intersect the earth in Alaska. Thus, in Alaska, there is a unique combination of large, accessible fuel sources at desirable field line intersections. Further, a particularly desirable fuel source for the generation of very large amounts of electricity is present in Alaska in abundance, this source being natural gas. The presence of very large amounts of clean-burning natural gas in Alaskan latitudes, particularly on the North Slope, and the availability of magnetohydrodynamic (MHD), gas turbine, fuel cell, electrogasdynamic (EGD) electric generators which operate very efficiently with natural gas provide an ideal power source for the unprecedented power requirements of certain of the applications of this invention. For a more detailed discussion of the various means for generating electricity from hydrocarbon fuels, see "Electrical Aspects of Combustion", Lawton and Weinberg, Clarendon Press, 1969. For example, it is possible to generate the electricity directly at the high frequency needed to drive the antenna system. To do this, typically the velocity of flow of the combustion gases (v), past magnetic field perturbation of dimension d (in the case of MHD), follow the rule:

$$v=df$$

where f is the frequency at which electricity is generated. Thus, if $v=1.78\times10^6$ cm/sec and d=1 cm then electricity would be generated at a frequency of 1.78 mHz.

Put another way, in Alaska, the right type of fuel (natural gas) is naturally present in large amounts and at just the right magnetic latitudes for the most efficient practice of this invention, a truly unique combination of circumstances. Desirable magnetic latitudes for the practice of this invention interest the earth's surface both northerly and southerly of the equator, particularly desirable latitudes being those, both northerly and southerly, which correspond in magnitude with the magnetic latitudes that encompass Alaska.

Referring now to FIG. 2 a first ambodiment is illustrated where a selected region R_1 of plasma **12** is altered by electron cyclotron resonance heating to accelerate the electrons of plasma **12**, which are following helical paths along field line **11**.

To accomplish this result, electromagnetic radiation is transmitted at the outset, essentially parallel to line **11** via antenna **15** as right hand circularly polarized radiation wave **20**. Wave **20** has a frequency which will excite electron cyclotron resonance with plasma **12** at its initial or original altitude. This frequency will vary depending on the electron cyclotron resonance of region R_1 which, in turn, can be determined from available data based on the altitudes of region R_1, the particular field line **11** being used, the strength of the earth's magnetic field, etc. Frequencies of from about 20 to about 7200 kHz, preferably from about 20 to about 1800 kHz can be employed. Also, for any given application, there will be a threshhold (minimum power level) which is needed to produce the desired result. The minimum power level is a function of the level of plasma production and movement required, taking into consideration any loss processes that may be dominant in a particular plasma or propagation path.

As electron cyclotron resonance is established in plasma **12**, energy is transferred from the electromagnetic radiation **20** into plasma **12** to heat and accelerate the electrons therein and, subsequently, ions and neutral particles. As this process continues, neutral particles which are present within R_1 are ionized and absorbed into plasma **12** and this increases the electron and ion densities of plasma **12**. As the electron energy is raised to values of about 1 kilo electron volt (kev), the generated mirror force (explained below) will direct the excited plasma **12** upward along line **11** to form a plume R_2 at an altitude higher than that of R_1.

Plasma acceleration results from the force on an electron produced by a nonuniform static magnetic field $(\bar{B})$. The force, called the mirror force, is given by

$$F=-\mu\nabla B \qquad (2)$$

where μ is the electron magnetic moment and $\nabla \bar{B}$ is the gradient of the magnetic field, μ being further defined as:

$$W_\perp/B=mV_\perp^2/2B$$

where $W_\perp$ is the kinetic energy in the direction perpendicular to that of the magnetic field lines and B is the magnetic field strength at the line of force on which the guiding center of the particle is located. The force as represented by equation (2) is the force which is responsible for a particle obeying equation (1).

Since the magnetic field is divergent in region R_1, it can be shown that the plasma will move upwardly from the heating region as shown in FIG. **1** and further it can be shown that

$$\tfrac{1}{2}M_eV_{e\perp}{}^2(x) \approx \tfrac{1}{2}M_eV_{e\perp}{}^2(Y) + \tfrac{1}{2}M_iV_{i\,||}{}^2(Y) \qquad (3)$$

where the left hand side is the initial electron transverse kinetic energy; the first term on the right is the transverse electron kinetic energy at some point (Y) in the expanded field region, while the final term is the ion kinetic energy parallel to B at point (Y). This last term is what constitutes the desired ion flow. It is produced by an electrostatic field set up by electrons which are accelerated according to Equation (2) in the divergent field region and pulls ions along with them. Equation (3) ignores electron kinetic energy parallel to B because $V_{e\,||} \approx V_{i\,||}$, so the bulk of parallel kinetic energy resides in the ions because of their greater masses. For example, if an electromagnetic energy flux of from about 1 to about 10 watts per square centimeter is applied to region R, whose altitude is 115 km, a plasma having a density (N_e) of 10^{12} per cubic centimeter will be generated and moved upward to region R_2 which has an altitude of about 1000 km. The movement of electrons in the plasma is due to the mirror force while the ions are moved by ambipolar diffusion (which results from the electrostatic field). This effectively "lifts" a layer of plasma **12** from the ionosphere and/or magnetosphere to a higher elevation R_2. The total energy required to create a plasma with a base area of 3 square kilometers and a height of 1000 km is about 3×10^{13} joules.

FIG. **3** is an idealized representation of movement of plasma **12** upon excitation by electron cyclotron resonance within the earth's divergent force field. Electrons (e) are accelerated to velocities required to generate the necessary mirror force to cause their upward movement. At the same time neutral particles (n) which are present along line **11** in region $R_1$are ionized and become part of plasma **12**. As electrons (e) move upward along line **11**, they drag ions (i) and neutrals (n) with them but at an angle θ of about 13 degrees to field line **11**. Also, any particulates that may be present in region R_1, will be swept upwardly with the plasma. As the charged particles of plasma **12** move upward, other particles such as neutrals within or below R_1, move in to replace the upwardly moving particles. These neutrals, under some conditions, can drag with them charged particles.

For example, as a plasma moves upward, other particles at the same altitude as the plasma move horizontally into the region to replace the rising plasma and to form new plasma. The kinetic energy developed by said other particles as they move horizontally is, for example, on the same order of magnitude as the total zonal kinetic energy of stratospheric winds known to exist.

Referring again to FIG. **2**, plasma **12** in region R_1 is moved upward along field line **11**. The plasma **12** will then form a plume (cross-hatched area in FIG. **2**) which will be relatively stable for prolonged periods of time. The exact period of time will vary widely and be determined by gravitational forces and a combination of radiative and diffusive loss terms. In the previous detailed example, the calculations were based on forming a plume by producing 0+energies of 2 ev/particle. About 10 ev per particle would be required to expand plasma **12** to apex point C (FIG. **1**). There at least some of the particles of plasma **12** will be trapped and will oscillate between mirror points along field line **11**. This oscillation will then allow additional heating of the trapped plasma **12** by stochastic heating which is associated with trapped and oscillating particles. See "A New Mechanism for Accelerating Electrons in the Outer Ionosphere" by R. A. Helliwell and T. F. Bell, Journal of Geophysical Research, Vol. 65, No. 6, June, 1960. This is preferably carried out at an altitude of at least 500 km.

The plasma of the typical example might be employed to modify or disrupt microwave transmissions of satellites. If less than total black-out of transmission is desired (e.g., scrambling by phase shifting digital signals), the density of the plasma (N_e) need only be at least about 10^6 per cubic centimeter for a plasma orginating at an altitude of from about 250 to about 400 km and accordingly less energy (i.e., electromagnetic radiation), e.g., 10^8 joules need be provided. Likewise, if the density $N_e$is on the order of 10^8, a properly positioned plume will provide a reflecting surface for VHF waves and can be used to enhance, interfere with, or otherwise modify communication transmissions. It can be seen from the foregoing that by appropriate application of various aspects of this invention at strategic locations and with adequate power sources, a means and method is provided to cause interference with or even total disruption of communications over a very large portion of the earth. This invention could be employed to disrupt not only land based communications, both civilian and military, but also airborne communications and sea communications (both surface and subsurface). This would have significant military implications, particularly as a barrier to or confusing factor for hostile missiles or airplanes. The belt or belts of enhanced ionization produced by the method and apparatus of this invention, particularly if set up over Northern Alaska and Canada, could be employed as an early warning device, as well as a communications disruption medium. Further, the simple ability to produce such a situation in a practical time period can by itself be a deterring force to hostile action. The ideal combination of suitable field lines intersecting the earth's surface at the point where substantial fuel sources are available for generation of very large quantitities of electromagnetic power, such as the North Slope of Alaska, provides the wherewithal to accomplish the foregoing in a practical time period, e.g., strategic requirements could necessitate achieving the desired altered regions in time periods of two minutes or less and this is achievable with this invention, especially when the combination of natural gas and magnetohydrodynamic, gas turbine, fuel cell and/or EGD electric generators are employed at the point where the useful field lines intersect the earth's surface. One feature of this invention which satisfies a basic requirement of a weapon system, i.e., continuous checking of operability, is that small amounts of power can be generated for operability checking purposes. Further, in the exploitation of this invention, since the main electromagnetic beam which generates the enhanced ionized belt of this invention can be modulated itself and/or one or more additional electromagnetic radiation waves can be impinged on the ionized region formed by this invention as will be described in greater detail herein after with respect to FIG. **4**, a substantial amount of randomly modulated signals of very large power magnitude can be generated in a highly nonlinear mode. This can cause confusion of or interference with or even complete disruption of guidance systems employed by

even the most sophisticated of airplanes and missiles. The ability to employ and transmit over very wide areas of the earth a plurality of electromagnetic waves of varying frequencies and to change same at will in a random manner, provides a unique ability to interfere with all modes of communications, land, sea, and/or air, at the same time. Because of the unique juxtaposition of usable fuel source at the point where desirable field lines intersect the earth's surface, such wide ranging and complete communication interference can be achieved in a resonably short period of time. Because of the mirroring phenomenon discussed hereinabove, it can also be prolonged for substantial time periods so that it would not be a mere transient effect that could simply be waited out by an opposing force. Thus, this invention provides the ability to put unprecedented amounts of power in the earth's atmosphere at strategic locations and to maintain the power injection level, particularly if random pulsing is employed, in a manner far more precise and better controlled than heretofore accomplished by the prior art, particularly by the detonation of nuclear devices of various yeilds at various altitudes. Where the prior art approaches yielded merely transitory effects, the unique combination of fuel and desirable field lines at the point where the fuel occurs allows the establishment of, compared to prior art approaches, precisely controlled and long-lasting effects which cannot, practically speaking, simply be waited out. Further, by knowing the frequencies of the various electromagnetic beams employed in the practice of this invention, it is possible not only to interfere with third party communications but to take advantage of one or more such beams to carry out a communications network even though the rest of the world's communications are disrupted. Put another way, what is used to disrupt another's communications can be employed by one knowledgeable of this invention as a communications network at the same time. In addition, once one's own communication network is established, the far-reaching extent of the effects of this invention could be employed to pick up communication signals of other for intelligence purposes. Thus, it can be seen that the disrupting effects achievable by this invention can be employed to benefit by the party who is practicing this invention since knowledge of the various electromagnetic waves being employed and how they will vary in frequency and magnitude can be used to an advantage for positive communication and eavesdropping purposes at the same time. However, this invention is not limited to locations where the fuel source naturally exists or where desirable field lines naturally intersect the earth's surface. For example, fuel, particularly hydrocarbon fuel, can be transported by pipeline and the like to the location where the invention is to be practiced.

FIG. 4 illustrates another embodiment wherein a selected region of plasma R_3which lies within the earth's ionosphere is altered to increase the density thereof whereby a relatively stable layer **30** of relatively dense plasma is maintained within region R_3. Electromagnetic radiation is transmitted at the outset essentially parallel to field line **11** via antenna **15** as a right hand circularly polarized wave and at a frequency (e.g., 1.78 megahertz when the magnetic field at the desired altitude is 0.66 gauss) capable of exciting electron cyclotron resonance in plasma **12** at the particular altitude of plasma **12**. This causes heating of the particles (electrons, ions, neutrals, and particulates) and ionization of the uncharged particles adjacent line **11**, all of which are absorbed into plasma **12** to increase the density thereof. The power transmitted, e.g., 2×10^6 watts for up to 2 minutes heating time, is less than that required to generate the mirror force F required to move plasma **12** upward as in the previous embodiment.

While continuing to transmit electromagnetic radiation **20** from antenna **15**, a second electromagnetic radiation beam **31**, which is at a defined frequency different from the radiation from antenna **15**, is transmitted from one or more second sources via antenna **32** into layer **30** and is absorbed into a portion of layer **30** (cross-hatched area in FIG. 4). The electromagnetic radiation wave from antenna **32** is amplitude modulated to match a known mode of oscillation f_3 in layer **30**. This creates a resonance in layer **30** which excites a new plasma wave **33** which also has a frequency of f_3 and which then propogates through the ionosphere. Wave **33** can be used to improve or disrupt communications or both depending on what is desired in a particular application. Of course, more than one new wave **33** can be generated and the various new waves can be modulated at will and in a highly nonlinear fashion.

FIG. **5** shows apparatus useful in this invention, particularly when those applications of this invention are employed which require extremely large amounts of power. In FIG. **5** there is shown the earth's surface **40** with a well **41** extending downwardly thereinto until it penetrates hydrocarbon producing reservoir **42**. Hydrocarbon reservoir **42** produces natural gas alone or in combination with crude oil. Hydrocarbons are produced from reservoir **42** through well **41** and wellhead **43** to a treating system **44** by way of pipe **45**. In treater **44**, desirable liquids such as crude oil and gas condensates are separated and recovered by way of pipe **46** while undesirable gases and liquids such as water, H_2S, and the like are separated by way of pipe **47**. Desirable gases such as carbon dioxide are separated by way of pipe **48**, and the remaining natural gas stream is removed from treater **44** by way of pipe **49** for storage in conventional tankage means (not shown) for future use and/or use in an electrical generator such as a magnetohydrodynamic, gas turbine, fuel cell or EGD generator **50**. Any desired number and combination of different types of electric generators can be employed in the practice of this invention. The natural gas is burned in generator **50** to produce substantial quantities of electricity which is then stored and/or passed by way of wire **51** to a transmitter **52** which generates the electromagnetic radiation to be used in the method of this invention. The electromagnetic radiation is then passed by way of wire **53** to antenna **54** which is located at or near the end of field line **11**. Antenna **54** sends circularly polarized radiation wave **20** upwards along field line **11** to carry out the various methods of this invention as described hereinabove.

Of course, the fuel source need not be used in its naturally-occurring state but could first be converted to another second energy source form such as hydrogen, hydrazine and the like, and electricity then generated from said second energy source form.

It can be seen from the foregoing that when desirable field line **11** intersects earth's surface **40** at or near a large naturally-occurring hydrocarbon source **42**, exceedingly large amounts of power can be very efficiently produced and transmitted in the direction of field lines. This is particularly so when the fuel source is natural gas and magnetohydrodynamic generators are employed. Further, this can all be accomplished in a

relatively small physical area when there is the unique coincidence of fuel source **42** and desirable field line **11**. Of course, only one set of equipment is shown in FIG. **5** for sake of simplicity. For a large hydrocarbon reservoir **42**, a plurality of wells **41** can be employed to feed one or more storage means and/or treaters and as large a number of generators **55** as needed to power one or more transmitters **52** and one or more antennas **54**. Since all of the apparatus **44** through **54** can be employed and used essentially at the sight where naturally-occurring fuel source **42** is located, all the necessary electromagnetic radiation **20** is generated essentially at the same location as fuel source **42**. This provides for a maximum amount of usable electromagnetic radiation **20** since there are no significant storage or transportation losses to be incurred. In other words, the apparatus is brought to the sight of the fuel source where desirable field line **11** intersects the earth's surface **40** on or near the geographical location of fuel source **42**, fuel source **42** being at a desirable magnetic latitude for the practice of this invention, for example, Alaska.

The generation of electricity by motion of a conducting fluid through a magnetic field, i.e., magnetohydrodynamics (MHD), provides a method of electric power generation without moving mechanical parts and when the conducting fluid is a plasma formed by combustion of a fuel such as natural gas, an idealized combination of apparatus is realized since the very clean-burning natural gas forms the conducting plasma in an efficient manner and the thus formed plasma, when passed through a magnetic field, generates electricity in a very efficient manner. Thus, the use of fuel source **42** to generate a plasma by combustion thereof for the generation of electricity essentially at the site of occurrence of the fuel source is unique and ideal when high power levels are required and desirable field lines **11** intersect the earth's surface **40** at or near the site of fuel source **42**. A particular advantage for MHD generators is that they can be made to generate large amounts of power with a small volume, light weight device. For example, a 1000 megawatt MHD generator can be construed using superconducting magnets to weigh roughly 42,000 pounds and can be readily air lifted.

This invention has a phenomenal variety of possible ramifications and potential future developments. As alluded to earlier, missile or aircraft destruction, deflection, or confusion could result, particularly when relativistic particles are employed. Also, large regions of the atmosphere could be lifted to an unexpectedly high altitude so that missiles encounter unexpected and unplanned drag forces with resultant destruction or deflection of same. Weather modification is possible by, for example, altering upper atmosphere wind patterns or altering solar absorption patterns by constructing one or more plumes of atmospheric particles which will act as a lens or focusing device. Also as alluded to earlier, molecular modifications of the atmosphere can take place so that positive environmental effects can be achieved. Besides actually changing the molecular composition of an atmospheric region, a particular molecule or molecules can be chosen for increased presence. For example, ozone, nitrogen, etc. concentrations in the atmosphere could be artificially increased. Similarly, environmental enhancement could be achieved by causing the breakup of various chemical entities such as carbon dioxide, carbon monoxide, nitrous oxides, and the like. Transportation of entities can also be realized when advantage is taken of the drag effects caused by regions of the atmosphere moving up along diverging field lines. Small micron sized particles can be then transported, and, under certain circumstances and with the availability of sufficient energy, larger particles or objects could be similarly affected. Particles with desired characteristics such as tackiness, reflectivity, absorptivity, etc., can be transported for specific purposes or effects. For example, a plume of tacky particles could be established to increase the drag on a missile or satellite passing therethrough. Even plumes of plasma having substantially less charged particle density than described above will produce drag effects on missiles which will affect a lightweight (dummy) missile in a manner substantially different than a heavy (live) missile and this affect can be used to distinguish between the two types of missiles. A moving plume could also serve as a means for supplying a space station or for focusing vast amount of sunlight on selected portions of the earth. Surveys of global scope could also be realized because the earth's natural magnetic field could be significantly altered in a controlled manner by plasma beta effects resulting in, for example, improved magnetotelluric surveys. Electromagnetic pulse defenses are also possible. The earth's magnetic field could be decreased or disrupted at appropriate altitudes to modify or eliminate the magnetic field in high Compton electron generation (e.g., from high altitude nuclear bursts) regions. High intensity, well controlled electrical fields can be provided in selected locations for various purposes. For example, the plasma sheath surrounding a missile or satellite could be used as a trigger for activating such a high intensity field to destroy the missile or satellite. Further, irregularities can be created in the ionosphere which will interfere with the normal operation of various types of radar, e.g., synthetic aperture radar. The present invention can also be used to create artificial belts of trapped particles which in turn can be studied to determine the stability of such parties. Still further, plumes in accordance with the present invention can be formed to simulate and/or perform the same functions as performed by the detonation of a "heave" type nuclear device without actually having to detonate such a device. Thus it can be seen that the ramifications are numerous, far-reaching, and exceedingly varied in usefulness.

I claim:

1. A method for altering at least one region normally existing above the earth's surface with electromagnetic radiation using naturally-occurring and diverging magnetic field lines of the earth comprising transmitting first electromagnetic radiation at a frequency between 20 and 7200 kHz from the earth's surface, said transmitting being conducted essentially at the outset of transmission substantially parallel to and along at least one of said field lines, adjusting the frequency of said first radiation to a value which will excite electron cyclotron resonance at an initial elevation at least 50 km above the earth's surface, whereby in the region in which said electron cyclotron resonance takes place heating, further ionization, and movement of both charged and neutral particles is effected, said cyclotron resonance excitation of said region is continued until the electron concentration of said region reaches a value of at least 10^6 per cubic centimeter and has an ion energy of at least 2 ev.

2. The method of claim **1** including the step of providing artificial particles in said at least one region which are excited by said electron cyclotron resonance.

3. The method of claim **2** wherein said artificial particles are provided by injecting same into said at least one region from an orbiting satellite.

4. The method of claim **1** wherein said threshold excitation of electron cyclotron resonance is about 1 watt per cubic centimeter and is sufficient to cause movement of a plasma region along said diverging magnetic field lines to an altitude higher than the altitude at which said excitation was initiated.

5. The method of claim **4** wherein said rising plasma region pulls with it a substantial portion of neutral particles of the atmosphere which exist in or near said plasma region.

6. The method of claim **1** wherein there is provided at least one separate source of second electromagnetic radiation, said second radiation having at least one frequency different from said first radiation, impinging said at least one second radiation on said region while said region is undergoing electron cyclotron resonance excitation caused by said first radiation.

7. The method of claim **6** wherein said second radiation has a frequency which is absorbed by said region.

8. The method of claim **6** wherein said region is plasma in the ionosphere and said second radiation excites plasma waves within said ionosphere.

9. The method of claim **8** wherein said electron concentration reaches a value of at least 10^{12} per cubic centimeter.

10. The method of claim **8** wherein said excitation of electron cyclotron resonance is initially carried out within the ionosphere and is continued for a time sufficient to allow said region to rise above said ionosphere.

11. The method of claim **1** wherein said excitation of electron cyclotron resonance is carried out above about 500 kilometers and for a time of from 0.1 to 1200 seconds such that multiple heating of said plasma region is achieved by means of stochastic heating in the magnetosphere.

12. The method of claim **1** wherein said first electromagnetic radiation is right hand circularly polarized in the northern hemisphere and left hand circularly polarized in the southern hemisphere.

13. The method of claim **1** wherein said electromagnetic radiation is generated at the site of a naturally-occurring hydrocarbon fuel source, said fuel source being located in at least one of northerly or southerly magnetic latitudes.

14. The method of claim **13** wherein said fuel source is natural gas and electricity for generating said electromagnetic radiation is obtained by burning said natural gas in at least one of magnetohydrodynamic, gas turbine, fuel cell, and EGD electric generators located at the site where said natural gas naturally occurs in the earth.

15. The method of claim **14** wherein said site of natural gas is within the magnetic latitudes that encompass Alaska.

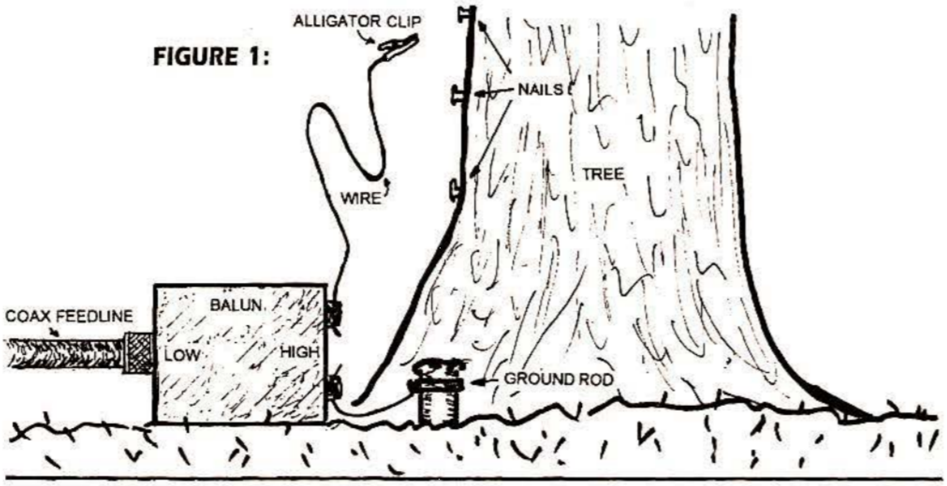
Prehistoric Radio!

If you've been following the "Below 500 kHz" column, you know that natural phenomena right here on earth have been producing, transmitting, and receiving radio signals since time began. Lightning bolts, and some other mighty reactions in nature, produce great amounts of electromagnetic radiation in the light, heat, and the radio portions of the electromagnetic-wave spectrum. Lightning discharges from tropical storms in particular are continually producing wide-band radio waves that propagate worldwide. You receive these signals as bothersome static noise on the LF, MF, and on HF bands.

FIGURE 1:



Connecting a feedline to a tree antenna. Nail small, thort, thin nails into the tree about every two or three feet, up to 10 or 15 feet high. Connect the clip to the various nails until best results are achieved. The balun is a 4:1 ratio or higher, high side to the tree.

Weak-signal operators who do moon-bounce work are only too well acquainted with the radio signals which our own sun transmits. These noisy signals can totally mask over moon-bounce signals when the sun and moon are both in the same direction from moon-bouncer's antenna. Radio waves known as "cosmic noise" are continually bombarding our antennas with radio signals generated by natural reactions occurring in galactic space. As a matter of fact, the discovery that the source of this particular radio noise lay outside our solar system marked the beginning of radio astronomy. In radio astronomy, naturally occurring radio signals from space are studied in an attempt to learn more about the cosmos.

OK, so there were radio signals before we were around to know about it, but what about the reception of those waves? Who received those signals? No person received them, but they were received by every naturally-occurring conductor to which they propagated. And, once trees evolved, they provided natural, grounded-vertical Marconi antennas to receive these waves.

Well, but where was the receiver for those antennas? The resistance of the tree's "body" was the "receiver." This resistance dissipated much of the received energy as heat rather than as sound, like the loudspeaker does in our HF receivers.

Of course, natural transmission and reception still goes on today. Have you asked the trees near your home if they have received any RF signals lately? I have. And the trees which I asked told me that they receive lots of signals—and I haven't gone off my rocker! They receive lightning-generated signals just as they have since time immemorial, and they also receive the signals which man puts onto the airwaves today.

How did I ask the trees? It's simple. I just connected a feedline to a tree, and connected the line to my receiver. I received a multitude of signals across the LF, MF, and HF bands. If I had tried other bands I would have, no doubt, received signals on those bands, too. As a matter of fact, a tall, live tree makes a decent LF-MF-HF antenna.

■ Tree-Antennas Throughout Radio's History

Old time radio expert Squires reported using trees as receiving aerials for distances of 50 kilometers. His method was to hammer a nail into the tree a few yards above the ground, and connect the receiver's antenna input connectors to the nail and to a ground.

Texanna Loomis, daughter of wireless communication pioneer Mahlon Loomis, says in her *Radio Theory and Operating* that "It has been found that a tree can be used for a receiving antenna, preferably an oak, by attaching a lead-in wire to the trunk of the tree."

Another old-time radio expert named Morecroft felt that reception came from the lead-in wire, rather than the tree itself. In my own tests I can't agree with Morecroft, because my lead-in was shielded, grounded coax, the attachment connectors to the tree were short, and the antenna performed much more like a long antenna than a short stub.

In more recent times there have also been reports of tree antennas. Cohen, in the April 1996 issue of *73 Magazine*, reports using a tree antenna on VHF and UHF with "mediocre-to-good results," but no acceptable results for lower bands. Perhaps his use of trees only 20 feet tall limited their performance on lower bands.

Also in *73* (May 1990), JA6HW and JA6AUI report using a 12 foot high tree for both transmitting and receiving on the 10 meter band with good results. Their article also says that hams used live-tree antennas in the 1930's, as did the U. S. Forces in Vietnam. In *Monitoring Times*, April 1989, Dr. Kosta reports that trees "frequently work better than conventional antennas" for television reception. In the September 1990 issue of *Monitoring Times* yours truly reports good results with a tall maple tree on LF through HF.

Tapping into Natural Radio

Figure 1 shows suggestions on utilizing a tree as an antenna. For HF, I suggest using the tallest tree available. Perhaps shorter trees would be better for VHF-UHF as in the 1990 *73* article discussed above—or perhaps not. As with any outside antenna it is wise to utilize some form of lightning protection.

RADIO RIDDLES

Last month:

I said, "Let's say that we could stain some radio waves, frozen at one moment in time, with some kind of dye so that we could actually see them. Of course we can't do this, except in our imagination. But if we did, how would the waves appear to us?"

For the area occupied by the waves at any one instant in time we would be trying to visualize the variations in the signal's electrical-field strength, and the reversals in field orientation (showing when the RF current changes direction of flow twice each cycle). This wouldn't look like a wavy line, or a sine wave graph as is represented in most texts on radio.

One way to imagine seeing the frozen waves is to envision that the space which the radio waves fill will show a darker shade of gray where their field strength is more intense, and a lighter shade where their field strength is weaker. For simplicity, let's consider only direct-wave propagation with no reflections or other impediments to the wave's travel between the transmitting antenna and receiving antenna.

In the space between the two antennas we would see bands of differing shades of gray oriented at right angles to the wave's direction of travel. There would be darker bands, less dark bands just next, even less dark bands next till a relatively light shade of gray was reached. Then somewhat darker bands, then even darker bands, and on to produce a sort of zebra-skin look. The darkest bands would be a half wavelength apart as would the lightest ones.

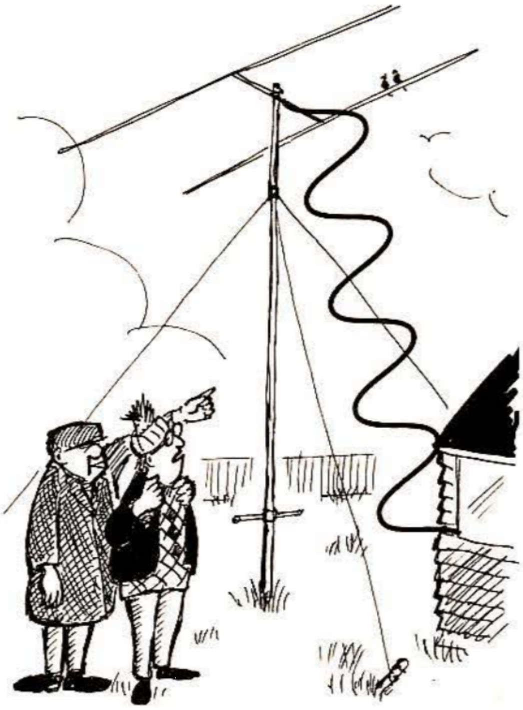
If we added a green tinge to our gray to indicate one orientation of the electrical field, and a red tinge for the field's other orientation then, starting at the middle of a darker band there would be greenish gray for a half wavelength along the direction of wave travel, a reddish gray for the next half wavelength, and so on.

Of course this picture is an over-simplification. For instance, we haven't talked about the wave's magnetic field, the polarization of the wave, or the spherical shape of the wavefront. But this simplified picture does cover the basic idea of radio waves in space.

This Month:

Let's say that, instead of freezing the waves, we had the advanced eyes and brains of some specialized android so that we could actually watch radio waves zip along on their 186,000 miles per hour flight from the transmitting antenna to our receiving antenna? How would those rascals look then?

You'll find an answer for this month's riddle, and much more, in next month's issue of *Monitoring Times*. 'Til then Peace, DX, and 73.



"You know, I thought those were classic standing radio waves until I read Clem Small's column this month. Now, I don't know what the heck they are!"

Solar TV Reception Booster

Here is a versatile rooftop TV reception booster that will add a full 18 dB of gain to the incoming TV signals at your receiver. This means no more ghosts, clearer pictures, and perhaps even reception of a distant station you could not get before. Best of all, this gadget is powered by an inexpensive solar cell that will virtually run forever without requiring replacement. Additionally, the circuit is designed with a charger circuit and reserve pack.

You can build it as is, or only include as much as you would like. For example, if you break the circuit where the X's are indicated, your booster will thrive entirely off its solar battery. If you break it at the two Y's, the solar cell charges a 4½-volt battery pack during the day so the booster will work just as well at night as in direct sunlight. If you include all the circuit (taking into account the indoor AC supply shown), you can occasionally recharge the 4½-volt pack just in case you have had a protracted period of rain or overcast weather which prevented the solar cell from sending its energy down to the reserve battery.

Construction is not complicated, but since you are dealing with both vhf and uhf signals, you will have to keep all leads extremely short and direct. In fact, you would do best to cram the parts close together so as to cut down on the length of interconnecting wires. Looking at the schematic, you will note that Q1 must be grounded; this is no problem; however, since the HEP-3 comes with four leads instead of the regular three. Turning the transistor upside down, you will notice an arrangement of leads as shown and identified in Fig. 17.

Fig. 17. Solar TV reception booster.

Take care in constructing your coils that you duplicate exactly those turns and techniques recommended in Table 17.

Once complete, you can test out your booster by hooking it to the TV set and placing a lit 60-watt lamp bulb in rather close proximity to M5. As the lamp is turned on, you should get a much-improved picture. Adjust the best reception on all channels by tuning L4 and the coupling between L1 and L2. Now mount at the TV antenna, positioning M5 for best sunlight hits.

Hint: Leave the AC plug plugged in at all times. It will not draw power until you throw switch S1 onto "charge."

Table 17. Parts List for Solar TV Reception Booster.

Item No.	Description
C1	56-pF capacitor.
C2, C3, C6	.0022-μF capacitors.
C4	1.5-pF capacitor.
C5	18-pF capacitor.
C7	150-μF, 15-w VDC electrolytic capacitor.
C8, C9	.0022-μF capacitors.
L1	7½ turns No. 24 enameled wire, evenly wound on a 3/16-inch-diameter form.
L2	3 turns No. 24 enameled wire evenly wound on a 3/16-inch-diameter form.
L3	17 turns No. 24 enameled wire evenly wound on a 3/16-inch-diameter form.
L4	11½ turns of No. 24 enameled wire evenly wound on Speer Type E ferrite form.
L5, L6	10 turns No. 24 enameled wire evenly wound on Speer Type E ferrite form.
M1	4½ VDC, with three penlites of NiCd cells.
M2, M3	Binding posts.
M4	AC wall plug with cable clamp.
M5	4½-VDC Solar pack. (International Rectifier No. SP5G26C or equiv.)
Q1	HEP-3 transistor.
R1	51K resistor.
R2	30K resistor.
R3	240-ohm resistor.
R4	110-ohm resistor.
R5	750-ohm resistor.
S1	Spst switch.
T1, T2, T3, T4	Using Ferroxcube K5050-06 ferrite cores, insert 2 turns of special 300-ohm miniature twinlead in each form hole. Pull tight, and connect leads where shown in diagram.

Free-Power AM Radio Receiver

Strange as it may seem, this transistor broadcast-band radio receiver "steals" power from one station to give to another! The principle is basic: By tuning the battery-section antenna coil (L2) to the strongest broadcast station on the band, diode X1 can rectify the rf and convert it into DC current. Naturally, the closer you are to a strong station, the more current the "radio battery" section of your radio receiver will be able to supply. Once you have found this spot, the DC current is passed on to power the transistor circuit which acts as a genuine receiver, with the full tuning it affords. See Fig. 18 and Table 18.

The basic consideration is a good antenna and ground, the latter preferably being made to a water pipe or solid external ground composed of a pipe driven at least 4 feet into moist earth. This procedure not only ensures maximum signal pickup for the radio-battery portion of the circuit, but also provides best results for the GE-2 receiver circuit.

Once completed, just tune the radio battery as explained in the first paragraph and calibrate your receiver by adjusting L1 so that the bottom of the band occurs when C1 is fully meshed. If you have a local broadcast station operating near 540 kHz, this simplifies things tremendously. Once the calibration procedure is complete, forget entirely about adjusting L1 and do all your listening by tuning C1.

Schumann Resonances[1]

Janis Galejs

Applied Research Laboratory, Sylvania Electronic Systems, a Division of Sylvania Electric Products Inc.,
40 Sylvan Road, Waltham, Mass. 02154

(Received February 3, 1965)

This paper reviews the current work in the field of Schumann resonances and discusses the topics of waveforms and frequency estimates, resonance frequencies and Q factors, source distributions and noise spectra, diurnal and seasonal changes of power spectra, and variations of resonance frequencies. Observations of the above phenomena are correlated with theoretical considerations.

1. Introduction

The resonances in the spherical shell between the earth and ionosphere that are due to azimuthal waves have been considered in two recent survey papers [Galejs, 1964a; Wait, 1964a]. This work contains experimental data as well as the required theory. The basic theory of the resonances has been reviewed by Wait [1964b]. In the present summary the emphasis will be on correlation between measurements and available theory. There will be no extensive analytical developments, but frequent references will be made to literature.

Based on theoretical considerations, Schumann [1952a, b, 1957] postulated resonances of the earth-to-ionosphere cavity. Koenig [1958, 1959, 1961] obtained the first experimental indication of Schumann resonances by observing noise waveforms in the output of a narrow band amplifier. Detailed frequency spectra of this noise were first obtained by Balser and Wagner [1960]. Other measurements have been reported by Fournier [1960]; Benoit and Houri [1961, 1962]; Lokken et al. [1961, 1962]; Polk and Fitchen [1962]; Gendrin and Stefant [1962a]; Balser and Wagner [1962a, b, 1963]; Rycroft [1963]; Chapman and Jones [1964].

The fundamental theory of Schumann resonances [Schumann 1952a, b, 1957] is discussed in a book by Wait [1962]. Raemer [1961a, b] considers the observable noise spectra as the response of the earth-to-ionosphere cavity due to lightning flashes all over the world, but the homogeneous sharply bounded ionosphere model of Raemer introduces high losses, and he does not succeed in reproducing the spectral measurements of Balser and Wagner [1960]. Galejs [1961a, b] uses an isotropic ionosphere model of exponentially increasing conductivity which is based on measured or calculated characteristics of the lower ionosphere. This model permits a close reproduction of the noise spectra measurements in the resonance region, and it also provides an agreement with measured ELF attenuation rates [Chapman and Macario, 1956; Jean et al., 1961].

Models of an anisotropic ionosphere are difficult to apply to the problem of earth-to-ionosphere cavity resonances because of the variations of the magnetic field vector along the surface of the earth. The propagation parameters can be estimated in the presence of a horizontal magnetic field component from the work of Galejs and Row [1964] and of Galejs [1964b]. The earth-to-ionosphere cavity resonances have been analyzed for a nonhomogeneous ionosphere in the presence of a radial (vertical) magnetic field by Thompson [1963] and Galejs [1965]. A thin-shell approximation of the ionosphere with a superimposed radial magnetic field has been considered by Wait [1964c]. Some other work of Wait [1963a, b], although intended for a different frequency range, can also be applied to the earth-to-ionosphere resonance problem in the presence of a radial magnetic field.

Additional references are available in the comprehensive bibliography by Brock-Nannestad [1962].

2. Waveforms and Frequency Estimates

In wide band recordings of atmospheric signals an ELF component or slow tail follows the initial VLF component of the transient [Hepburn and Pierce, 1953; Liebermann, 1956a, b; Tepley, 1959; Pierce, 1960]. An oscillatory structure of the signal becomes noticeable by passing it through a band-pass filter. An example of a noise recording in the output of a 2 to 30 c/s band-pass filter [Lokken, 1964, private communication] is shown in figure 1. The two horizontal magnetic field components have been observed simultaneously in Canada and in Antarctica. There is a correlation between the high intensity ELF noise bursts observed at the various sites. A recording of one of the waveforms is shown in figure 2. The darkened areas indicate resonance frequencies around 8, 14, and 20 c/s. Noise waveforms in the 5 to 20 c/s band have been reported by Polk and Fitchen [1962] and Polk [1962]. Figure 3 shows sample recordings of the outputs of two coils the axes of which are oriented in the north to south (N–S) and east to west (E–W) directions. Frequency of these waveforms has been estimated by counting the cycles between the second markers shown on the records. The average frequency computed in this procedure should be higher than the resonance frequencies of a spectral analysis [Galejs, 1962a, 1964a]. Noise recordings made simultaneously in Germany and in Rhode Island have been reported by Keefe, Polk, and Koenig [1964].

3. Resonance Frequencies and Q Factors

3.1. Definitions

A resonance frequency and Q factor may be determined from spectral measurements. Analytically it is also possible to compute the power spectrum of the noise waveform. However, it is more convenient to relate the resonance frequency and the Q factor to the analytically determined propagation parameters. The radial electrical field due to the vertical dipole excitation can be represented by

$$E_r = -\frac{iIds}{4\omega\epsilon h a^2}\,\frac{\nu(\nu+1)}{\sin\nu\pi}\,P_\nu(-\cos\theta) \tag{1}$$

where

$$\nu(\nu+1) = (k_0 a S)^2. \tag{2}$$

For a wave that propagates in the spherical shell between the earth and the ionosphere S is defined as the ratio of the complex wave number k to free space wave number $k_0(S = k/k_0)$. The real part of S can be seen to be inversely proportional to the phase velocity, and the imaginary part of S is proportional to the attenuation constant. This parameter S is determined from solving the appropriate boundary value problem of the earth, the air space and the chosen ionosphere model [Wait, 1962; Galejs, 1964a]. The resonance frequencies of the nth mode are determined from the minima of $\sin\nu\pi$ in (1) [Galejs, 1962a, 1964a] which gives

$$f_n \approx \frac{7.5\sqrt{n(n+1)}}{\mathrm{Re}S}. \tag{3}$$

Typical values of ReS are 1.4 to 1.2 for frequencies in the resonance region.

The cavity Q may be determined as a ratio between the stored energy and energy loss per cycle or simply by the width of the resonance curves. As shown in the appendix, in the present problem the electrically stored energy W_e differs from the magnetically stored energy W_h, and the Q definition should consider the sum of the average stored energies W_e and W_h. This expression for Q is

$$Q=\frac{(\mathrm{Re}S)^2+1}{4\mathrm{Re}S\,\mathrm{Im}S}. \tag{4}$$

When considering only the magnetically stored energy Q is given by

$$Q=\frac{1}{2\,\mathrm{Re}S\,\mathrm{Im}S}. \tag{5}$$

For a given set of propagation parameters this will give a lower Q figure than (4). This expression has been used in the past work of Galejs [1961a, 1962a, b, 1964a]. Considering only the electrically stored energy gives

$$Q=\frac{\mathrm{Re}S}{2\,\mathrm{Im}S}. \tag{6}$$

The last expression can also be derived from the concept of complex resonance frequencies [Wait, 1964a] or by considering the half-power band width of the resonance curve. All three Q definitions yield the same results as ReS approaches unity, but they will differ near the lower resonance frequency of the earth ionosphere cavity. Equation (4) will be used in the present calculation.

Experimentally determined Q values that are estimated from the half-power bandwidths of the resonance curves neglect the effects of adjacent resonances and of near-field noise that will tend to add to the background level. Hence, the half-power level is estimated too low, the apparent half-power bandwidth is larger and the estimated Q factor may be too low.

3.2. Characteristics of the Boundary

In the theoretical models that are advanced for explaining the resonance frequencies and the Q-factor measurements [Wait, 1962; Galejs, 1964a; Wait, 1964a] it is necessary to consider the boundary properties of the spherical shell.

In the frequency range of the resonances the displacement currents of ground are negligible and the ground conductivity $\sigma_g=10^{-3}$ to 1 mho/m is much higher than the effective ionospheric conductivity σ_i that is estimated to be of the order of 10^{-7} to 10^{-6} mho/m. The ground conductivity σ_g may be assumed as infinite in the first approximation and only the ionospheric properties require a detailed analysis.

The ionosphere acts as an anisotropic conductor and for a z-directed magnetic field its conductivity tensor is of the form

$$[\sigma]=\begin{bmatrix}\sigma_1 & -\sigma_2 & 0\\ \sigma_2 & \sigma_1 & 0\\ 0 & 0 & \sigma_0\end{bmatrix}. \tag{7}$$

Equations for computing the conductivity components are available in literature [Galejs, 1964a and b] and typical conductivity profiles are shown in figure 4 but some uncertainties still apply to such models [VanZandt, 1964]. The above computations consider the ion effects, but assume the operating frequency to be zero. These profiles can be further approximated by straight lines through the lower ionosphere in the semilogarithmic plots of figure 4, which corresponds to an expoential height variation of the conductivity components. In a further simplification the anisotropy may be ignored ($\sigma_1=\sigma_0$, $\sigma_2=0$). Even a simple one or two layer model can be assumed, such as shown in figure 5. These particular models have been used in past work by Raemer [1961a and b], Galejs [1962a and b], and by Chapman and Jones [1964]. In the isotropic exponential model the conductivity is given by

$$\sigma(z)=\sigma(z_0)\,\exp\,[\beta(z-z_0)] \tag{8}$$

where $z_0=60$ km and the day and night models are characterized by $\sigma(z_0)=4.63\times10^{-8}$ mho/m and $\beta=0.308$ km^{-1} and by $\sigma(z_0)=6.5\times10^{-10}$ mho/m and $\beta=0.44$ km^{-1}, respectively.

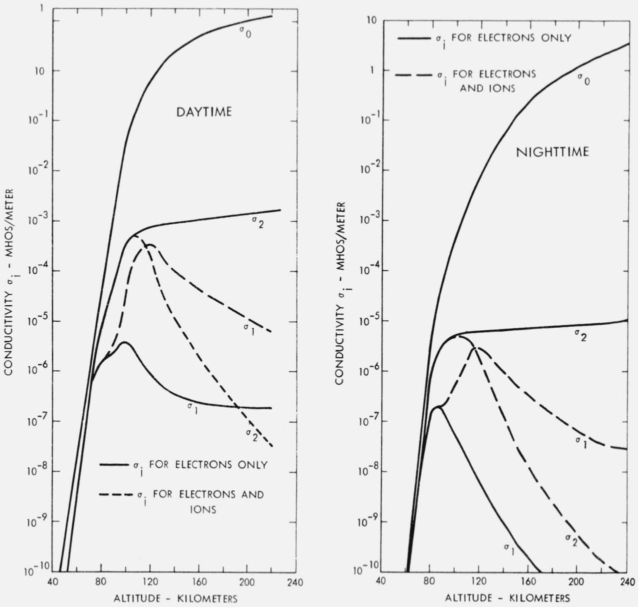

FIGURE 4. *Components of the tensor conductivity* F = 0.

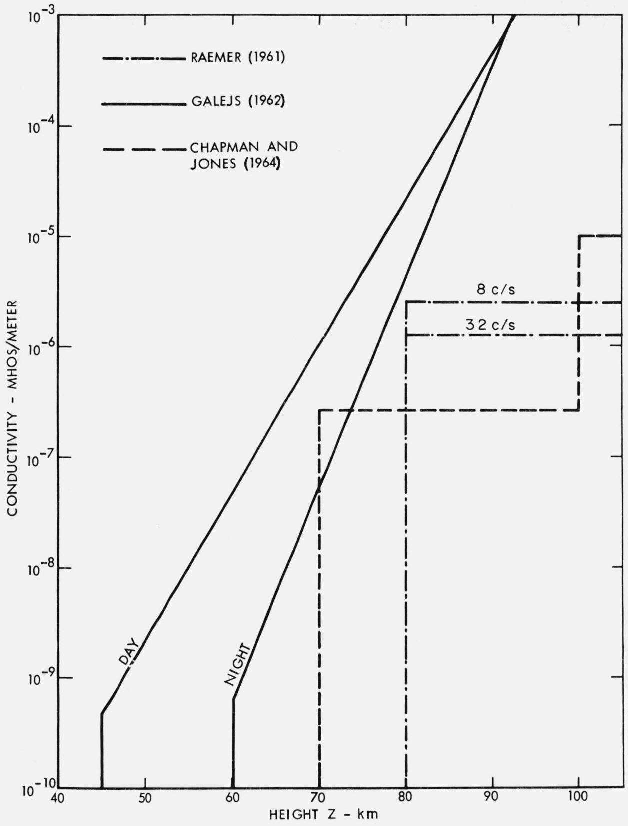

FIGURE 5. *Models of ionospheric conductivity.*

3.3. Single Layer Ionosphere

The single layer ionosphere model of Raemer [1961a and b] assumes the boundary height of the ionosphere to be constant, but the conductivity to change with frequency so as to obtain the correct resonant frequencies. However, the resulting *Q* factors are approximately two times lower than in measurements. The same difficulties are experienced with an ionosphere model of constant conductivity, but frequency dependent boundary height. Similar results are obtained by Madden [1961] with a conductivity of $\sigma = 1.8 \times 10^{-6}$ mho/m and the ionospheric boundary at $h = 80$ km. The deficiencies of a single layer ionosphere model are less pronounced if it is attempted to achieve only a partial match of the resonant frequencies, as seen from Wait [1964a]. However, the *Q* factors will be too low in particular at the higher resonance frequencies ($f \approx 30$ c/s).

Compressibility effects of the ionosphere have been considered by Seshadri [1965b] using the model of a perfectly conducting flat earth and a sharply bounded homogeneous isotropic and lossless ionosphere. The compressibility of the ionosphere does not affect the wave propagation below it for frequencies in the range of Schumann resonances and in the ELF band. However, the compressibility should be considered for waves that propagate inside the ionosphere [Seshadri, 1965a].

3.4. Two-Layer Ionosphere Models

Two-layer models give more accurate values of the resonance frequencies and of cavity *Q* or of the complex propagation parameter *S*. Two-layer and multilayer models have been discussed by Wait [1958, 1962]; Madden [1961]; Jean et al. [1961], and a particularly successful two-layer model has been constructed by Chapman and Jones [1964a, b]. This model, which is indicated in figure 5, has been applied in the frequency range of earth-to-ionosphere cavity resonances and also for frequencies up to 1 kc/s.

Such models are usually derived by trial and error procedures and they are difficult to correlate with continuous ionosphere profiles, such as shown in figure 4.

3.5. Models of Continuously Varying Ionosphere

The isotropic exponential model gives a reasonable approximation to the ionospheric conductivity versus height profile through the lower ionosphere layers, and the propagation parameters of the model can be determined from closed form expressions of the surface impedance [Galejs, 1961a, 1962a, b, 1964a]. Calculated resonance frequencies and *Q* factors that are based on (3), (4), and available values of *S* [Galejs, 1962a] are listed in tables I and II. Calculations are based on daytime or day and nighttime ionosphere models. The *Q* factors considered also the effects of cosmic ray ionization [Bourdeau et al., 1959] that give a nearly exponential conductivity versus height variation as indicated by Galejs [1962a]. Cosmic ray ionization decreases the effective *Q* figures, in particular for the lower frequencies. The calculated *Q* values are still somewhat higher than those estimated from experimental data.

3.6. Magnetic Field Effects

The magnetic field effects for a homogeneous sharply bounded ionosphere model have been discussed by Wait [1962] in a quasi-longitudinal approximation for a superimposed radial magnetic field and also for a transverse magnetic field (east-west or west-east propagation along the magnetic equator).

The propagation parameters have been determined by Galejs and Row [1964] and Galejs [1964a, 1964b] in the presence of a horizontal magnetic field. These data provide an indication of propagation characteristics of the waves near the magnetic equator, but they do not apply directly to the earth-ionosphere resonance problem, where the **H** vector is nearly horizontal only over a small surface portion of the earth.

The earth-ionosphere cavity resonance frequencies have been considered in the thesis of Thompson [1963] for a radial magnetic field. He uses a multilayer ionosphere model that approximates the continuous altitude variation of the conductivity tensor. The azimuthal field variation is expressed in terms of the Legendre polynomials $P_n(\cos\theta)$ for the nth mode. The wave equation has four different solutions for each of the ionosphere layers, but it has only two solutions for the space between the ionosphere and the perfectly conducting ground surface. The solution of the problem and the resonance condition for the mode n are obtained after multiplying a sequence of 4×4 matrices. In these computations the displacement currents of the ionosphere are neglected. The computed resonance frequencies are in agreement with measurements, but the Q values are in the range of 15 to 20, with the exception of nighttime anisotropic solutions, where $Q=7$ to 10. The lowering of the nighttime Q figures by the magnetic field has been attributed to wave penetration through the ionosphere and to energy thus escaping from the earth-ionosphere cavity.

Another solution to the problem of earth's ionosphere cavity resonance in the presence of a radial magnetic field is given by Galejs [1965]. The azimuthal field variation is expressed in terms of the Legendre functions $P_\nu(-\cos\theta)$, and the solution of the wave equation is set up so that the four solutions of the ionospheric layers where $\sigma > \omega\epsilon_0$ degenerate into two solutions for the lower ionospheric layers where $\sigma << \omega\epsilon_0$ and for free space. After computing the surface impedance at the lower boundary of the ionosphere, the propagation parameters are determined from the solutions of the modal equation for TM modes, althought the coupling between TE and TM modes is considered in the processes of computing the surface impedance. Only the vertically polarized TM modes are assumed to propagate below the ionosphere. Such assumptions have been justified for a single layer ionosphere model at higher frequencies [Wait 1962, p. 269] and for a thin ionospheric shell also for frequencies in the resonance range [Wait, 1964c].

In the numerical calculations the anisotropic ionosphere models are those of figure 4 and further calculations are made for ionosphere models which consider electrons and ions at an operating frequency of 20 c/s, as indicated in figures 3 and 4 of Galejs [1964b]. In the isotropic ionosphere models σ_0 remains unaltered, $\sigma_1 = \sigma_0$, and $\sigma_2 \rightarrow 0$. The calculated resonance frequencies f_n are listed in table III. The isotropic day or night models exhibit too high resonance frequencies, but the average for the anisotropic day or night models gives nearly correct results, although the first resonance occurs near 7.7 c/s. At night the various anisotropic models give different results, while their results are nearly the same for daytime or for the isotropic models. The calculated Q factors are listed in table IV. At daytime the Q factors are lowered slightly due to anisotropy. The losses are principally due to absorption in the lower D region where the collision frequencies are high and the magnetic field has only small effects. At nighttime the anisotropy reduces the Q values drastically, and the ions have a considerable effect. For the isotropic models the energy remains below the ionosphere, the losses in the lower ionosphere are small and the Q values are high. For the anisotropic models some energy penetrates the ionosphere and escapes from the earth to ionosphere cavity. Hence the Q figure is low.

	MEASUREMENTS		4	6

The previous calculations have assumed a constant radial magnetic field (S pole) all over the globe. A reversal of the static magnetic field (N pole) causes negligible differences in the propagation parameters or in the values of f_n and Q. Hence a model using the average of the radial magnetic field may provide a first order estimate of the anisotropy effects. The present calculations assume the radial magnetic of the polar regions to be extended over the whole surface of the globe and the anisotropy effects should be too pronounced. The analytical results are highly dependent on the detailed structure of the nighttime anisotropic ionosphere, and further studies of it may be in order.

4. Source Distributions and Noise Spectra

Most of the ELF energy is of terrestrial origin and is caused by thunderstorm activity, although there are some high latitude events of an apparent extraterrestrial origin. Such emissions of approximately 800 c/s have been detected near Kiruna, Sweden [Egeland, 1964] and of 14 to 17 c/s on Kerguelen Island in the Southern part of the Indian Ocean [Gendrin and Stephant, 1964, private communication]. The Spectran recording of the signals received at Kerguelen is shown in figure 6. The upper trace shows a normal signal with resonances near 8, 14, 20, and 25 c/s. There is an additional signal of 14 to 17 c/s on the two lower traces. When neglecting the presence of such extraneous signals the terrestrial noise spectra can be calculated after estimating the dipole moments of the sources and using propagation parameters that are appropriate to the selected ionosphere model.

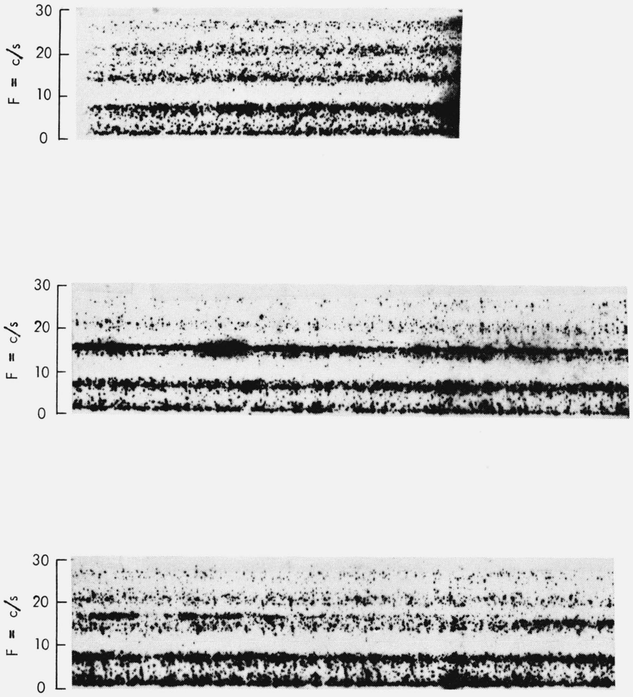

FIGURE 6. *Spectran recordings of noise waveforms at Kerguelen Island.*

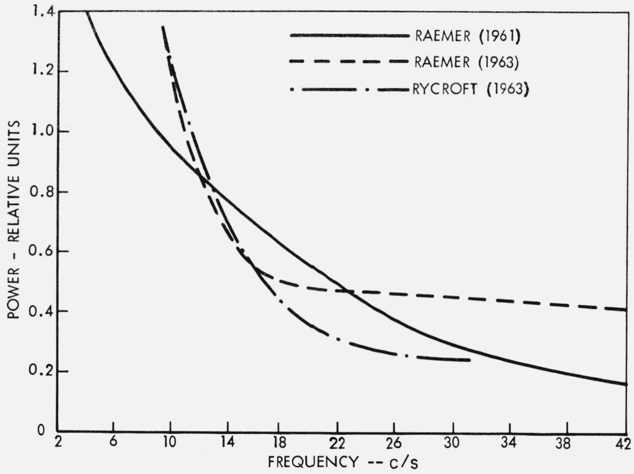

FIGURE 7. *Estimated lighting flash spectrum.*

Raemer [1961a, b] has estimated the power spectrum of the dipole moment in a median lightning flash Ids (or the first derivative of the electrostatic moment dM/dt) based on statistics of lightning strokes compiled by Williams [1959]. Later work of Raemer [1963 private communication] has lead to a revised estimate. These spectra are shown in figure 7. Pierce [1963] has computed the magnitude of the frequency spectra of the second derivative d^2M/dt^2, and Rycroft [1963] has calculated the frequency spectra of dM/dt using a similar representation of the lightning moments. The square of the frequency spectrum computed by Rycroft [1963] is also indicated in figure 7.

An equivalent power spectrum for the dipole moment of terrestrial noise sources has been deduced by Harris and Tanner [1962] from the measurements of Balser and Wagner [1960] by estimating the complex propagation constant within this frequency range in a "trial and error" approach. Harris and Tanner [1962] do not require an ionosphere model or any knowledge of lightning waveforms and their statistics for obtaining this equivalent power spectrum.

After determining the source spectra and the propagation parameters the power spectrum of the received noise may be computed from

$$G(i\omega)=\frac{g(i\omega)\,|\nu(\nu+1)|^2}{8(ak_0h)^2\,|\nu+\frac{1}{2}|\,[\cosh(2\pi\,\mathrm{Im}\,\nu)-\cos(2\pi\,\mathrm{Re}\,\nu)]}\cdot\left\{\frac{\sinh[2\,\mathrm{Im}\,\nu\,(\pi-\theta)]}{(-\mathrm{Im}\,\nu)}-\frac{\sin[(2\,\mathrm{Re}\,\nu+1)(\pi-\theta)-(\pi/2)]}{\mathrm{Re}\,\nu+\frac{1}{2}}\right\}_{\theta_1}^{\theta_2}, \quad (9)$$

where the ν is given by (2) and where the sources are assumed to be uniformly distributed in the θ interval of $\theta_1 < \theta < \theta_2$. The derivation of (9) starts from (1) and Legendre functions $P_\nu(-\cos\,\theta)$ are replaced by an asymptotic expansion. There are also equivalent spectral representations in terms of Legendre polynomials [Raemer, 1961a, b].

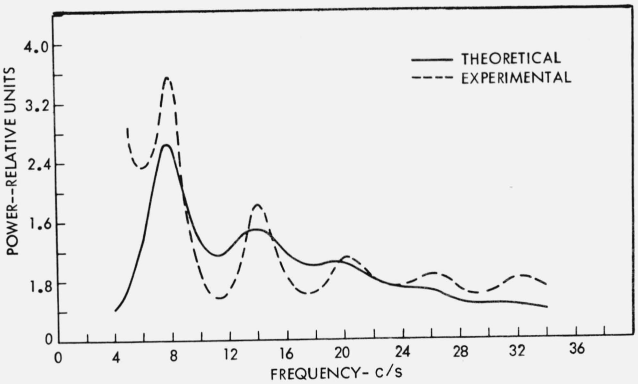

FIGURE 8. *ELF Noise spectrum—effective ionospheric height assumed constant.*

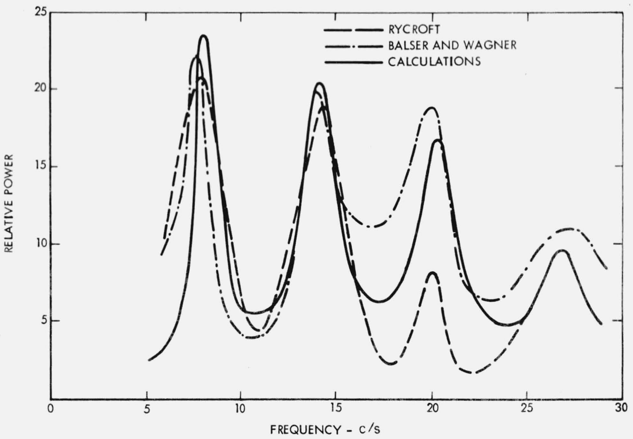

FIGURE 10. *Noise spectrum for 47° ≤ θ ≤ 128°.*

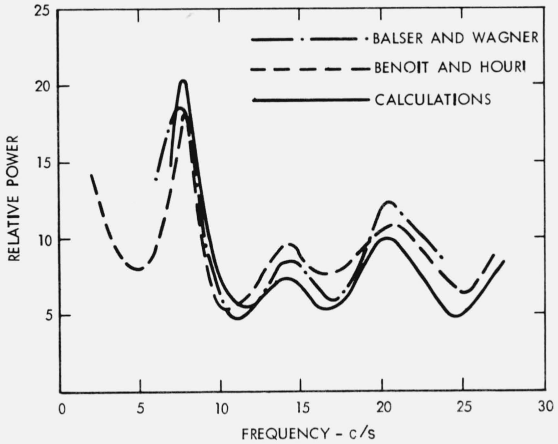

FIGURE 9. *Noise spectrum for 38° ≤ θ ≤ 72°.*

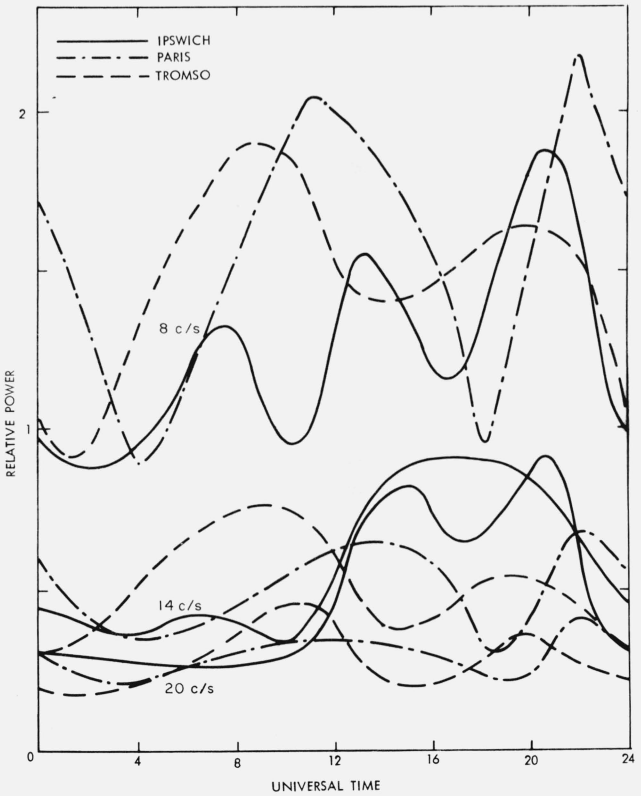

FIGURE 11. *Diurnal variation of the resonance modes at Ipswich, Mass., February 1961 (vertical electric field), Chambon-la-Foret (near Paris) July 1962 and at Tromso (Norway) April 1962 (horizontal magnetic field).*

The noise spectrum of Raemer [1961b] has been used for computing the observed noise spectra in conjunction with a sharply bounded ionosphere model. This spectrum is shown in figure 8 and is seen to exhibit excessively damped higher resonance peaks.

The exponential ionosphere model [Galejs, 1961b, 1962a, 1964a] produces a better agreement with measurements as seen in figures 9 and 10. In this work propagation is assumed to be uniform around the surface of the earth and the propagation parameters represent the average of day and night conditions. The sources are assumed to be uniformly distributed over the θ interval indicated in the figures (θ is defined with respect to the observer).

5. Diurnal and Seasonal Changes of Power Spectra

Balser and Wagner [1962a] have recorded diurnal variations of measured noise spectra. Their measurements of the diurnal variations of the power level at the first three resonance frequencies are shown in figure 11 together with similar measurements by Gendrin and Stefant [1962a]. Diurnal variations of the fields near the two lower resonance frequencies have been measured at Kingston, R.I., by Polk, Huck, and Yu [1963, private communication]. The maximum signal intensity occurs between 1500 and 1800 UT. In an amplitude versus time plot the signal peak is broader during summer than winter. Seasonal and diurnal variations of the noise power in the ELF frequency band below 35 c/s have been described by Wright [1963] without singling out the individual resonance modes. The measurements are made at Byrd Station, Antarctica (80°S, 120°W) and show peak intensities near 1000 UT during spring and summer and near 2300 UT during most of the year.

The gross features of the spectrum, such as the number of peaks and their approximate time of occurance, may be explained qualitatively by noting areas of globe with particularly high thunderstorm activity and by measuring the polar angle θ from these source regions to the observation point. The vertical electric field E_r and the horizontal magnetic field H_ϕ of the mode n exhibit the θ dependence of

$$E_r \sim P_n(\cos\theta) \tag{10}$$

$$H_\phi \sim \frac{d}{d\theta} P_n(\cos\theta), \tag{11}$$

where $P_n(\cos\theta)$ is a Legendre polynomial of the order n. A particular geographical region will contribute to the measured values of E_r or H_ϕ in the mode n if the right hand sides of (10) or (11) are sizeable for those values of θ. Such considerations have been reported by Balser and Wagner [1962a] and Gendrin and Stefant [1962a].

More detailed calculations have been carried out by Abraham [1964, private communication; Galejs 1964a] who used available estimates of geographical distributions of the noise sources and who calculated the day and night propagation effects after expressing the fields as a sum of recirculating azimuthal waves.

In the expression for the electric field component E_r of (1), the Legendre function is replaced by the leading term of its asymptotic expansion. The function $\sin \nu\pi$ is expanded into

$$(\sin \nu\pi)^{-1} = -2i \sum_{n=0}^{\infty} e^{i(2n+1)\nu\pi} \tag{12}$$

which is valid for Im $\nu > 0$. This results in [Abraham, 1964, private communication]

$$E_r = \frac{Ids}{2\omega\epsilon h a^2} \frac{\nu(\nu+1)}{\sqrt{2\pi(\nu+\frac{1}{2})\sin\theta}} e^{i\frac{3\pi}{4}}$$
$$\sum_{n=0}^{\infty} \left\{ e^{i(\nu+\frac{1}{2})(\theta+2n\pi) - i2n\frac{\pi}{2}} + e^{i(\nu+\frac{1}{2})[2\pi(n+1)-\theta] - i(2n+1)\frac{\pi}{2}} \right\}. \tag{13}$$

The first term of the summation represents a wave which has traveled the direct distance from the source to the observation point (θ) plus n full circles around the sphere ($2n\pi$), while experiencing a phase shift of ($-\pi/2$) radians at each traversal of the source point or its antipode. The other term of the summation represents a wave which has traveled toward the observation point across the antipode of the source ($2\pi-\theta$) and has made furthermore n circles around the sphere ($2n\pi$) and has also experienced a phase shift of ($-\pi/2$) radians at each traversal of the source point or its antipode. This physical interpretation of (13), which is equivalent to (1) for $\nu=$const., permits a heuristic consideration of the ν differences between the day and night hemispheres. The multiplicative ν factors in front of the n summation are assumed to be constant and equal to $\overline{\nu}$ which is intermediate between the day and night ν values. The θ factors of the exponentials are replaced by integrals in order to account for the ν variation seen by the circular wave front as it propagates in the θ-direction with respect to the source. The amplitude changes at the day and night boundary can be also considered for each traveling wave by assuming that the energy of the wave remains constant after passing the day and night boundary. This results in decreased amplitudes for the larger ionospheric height of the night hemisphere. In the numerical work the surface of the earth was subdivided into 10° cells. Each cell had a constant surface density of noise sources but a variation was allowed from cell to cell. The plots of thunderstorm days over the world were used to set relative values of lightning activity for each of the cells, by assuming that the distribution of squared dipole moment per unit area is directly proportional to the thunderstorm day plots according to the Handbook of Geophysics [1960]. The diurnal variations were accounted for by a multiplicative factor in terms of local time at the source [Williams, 1959]. The final equation used in the spectrum calculations is similar to (9), although it is algebraically more involved [Abraham, 1964, private communication].

The diurnal variations of the noise power at the first three Schumann resonances have been computed using the exponential ionosphere model of figure 5 and are shown in figure 12. The calculations have disregarded the noise sources near the antipode where the usual asymptotic approximation of the Legendre functions is inaccurate. Figure 12 shows a qualitative agreement with the measurements of Balser and Wagner [1962a], that are shown in figure 11.

An example of seasonal power variations is shown in figure 13. It indicates a decreased noise power near the higher frequencies and/or during winter months.

Based on measurements at one location of the earth it is also possible to predict the noise levels at other locations using this procedure of noise spectrum calculations. The noise that is due to a worldwide distribution of thunderstorms depends on the frequency variation and also on the absolute value of the power spectrum of the mean dipole moment of the source $g(i\omega, \theta, \phi)$. The θ and ϕ dependence may be estimated from the thunderstorm frequency maps as was indicated before, which leaves the absolute value and the frequency dependence of $g(i\omega)$ as an unknown. Assuming that $g(i\omega)$ is the same for all noise sources, it may be determined by making the calculations to agree with measurements at one particular location. This gives a uniquely determined noise distribution over the surface of the earth and the accuracy of this model can be checked by com-

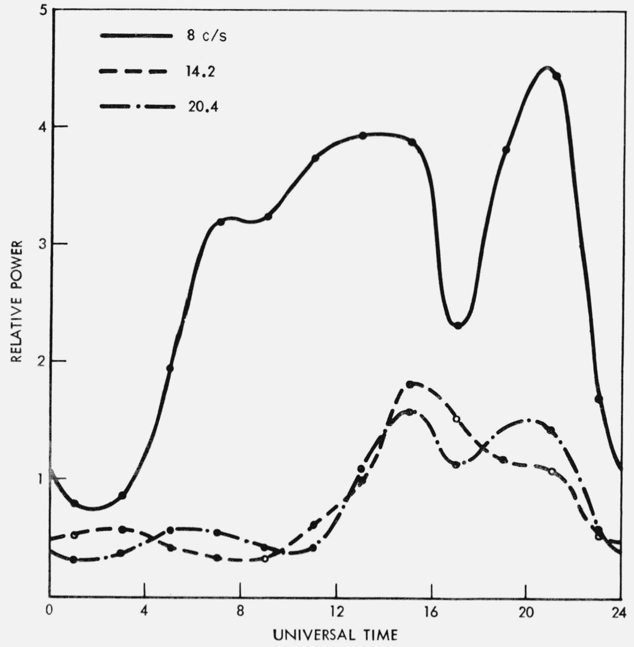

FIGURE 12. *Calculated diurnal variation of noise power at the peak of the resonance modes—wintertime—Boston, Mass.*

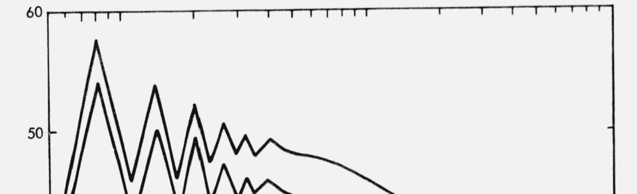

FIGURE 13. *Calculated noise spectrum for local noon in northern hemisphere.*

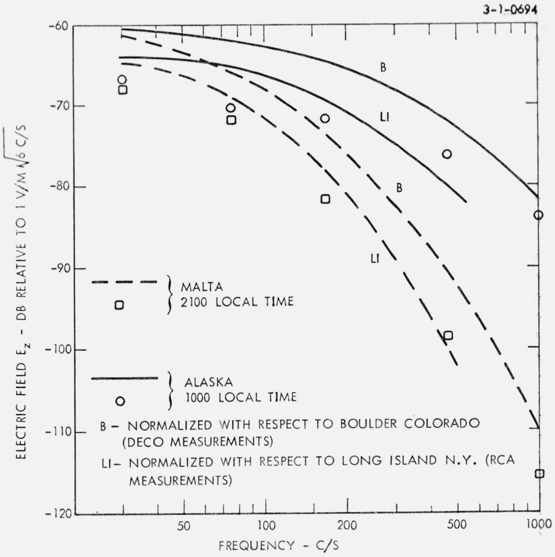

FIGURE 14. *Comparison of calculated field strength's data with July 1963 measurements by DECO and RCA.*

paring the calculations with measurements at other locations. In an example, measurements by DECO at Boulder, Colo., [Maxwell, 1963, private communication] and by RCA at Long Island, N.Y. [Powers, 1964, private communication], were used to determine $g(i\omega)$. The calculations by Abraham [1964, private communication] based on these values of $g(i\omega)$ have been compared with simultaneous measurements made in Malta and Alaska [Maxwell, 1963, private communication]. As seen from figure 14 the analytic curves agree in shape with the measurements, but the normalization with respect to Boulder gives somewhat higher predictions of the noise level. This may possibly be caused by summertime thunderstorm activity in the mountains near Boulder, Colo., that would give significant near-fields and a high estimate for the function $g(i\omega)$. The calculations are extended above the region of the earth-ionosphere cavity resonances to show that more significant noise level changes occur at higher frequencies.

In the calculations leading to figures 12 through 14 the day and night effects are considered most accurately if the day and night boundary is located symmetrically with respect to source (i.e., source at local noon or midnight). For nonsymmetrical day and night boundaries it is difficult to estimate the effects of wave front distortion. When neglecting such distortions (or assuming propagation strictly in the θ-direction), this method can account for $\nu(\theta)$ variations, which may be caused by ionosphere parameter changes or by changes of the static magnetic field along the surface of the earth. The assymptotic expansions of $P_\nu(-\cos\theta)$ used in (13) or (9) can be modified to increase their accuracy for observations near the source or its antipode [Abraham, 1965].

6. Variations of Resonance Frequencies

Diurnal frequency variations of the earth-ionosphere cavity modes have been reported by Balser and Wagner

[1962b], Gendrin and Stefant [1963], Rycroft [1963] and by Chapman and Jones [1964b]. The resonance frequencies vary by about ±0.2 to 0.3 c/s, but the changes are not simultaneous for the different modes; a low resonance frequency of one mode occurs simultaneously with a high frequency of a different mode.

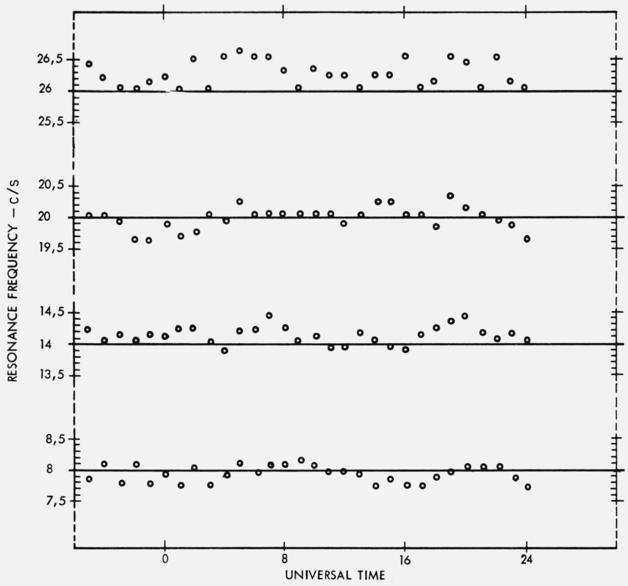

FIGURE 15. *Diurnal frequency variations measured by Gendrin and Stefant.*

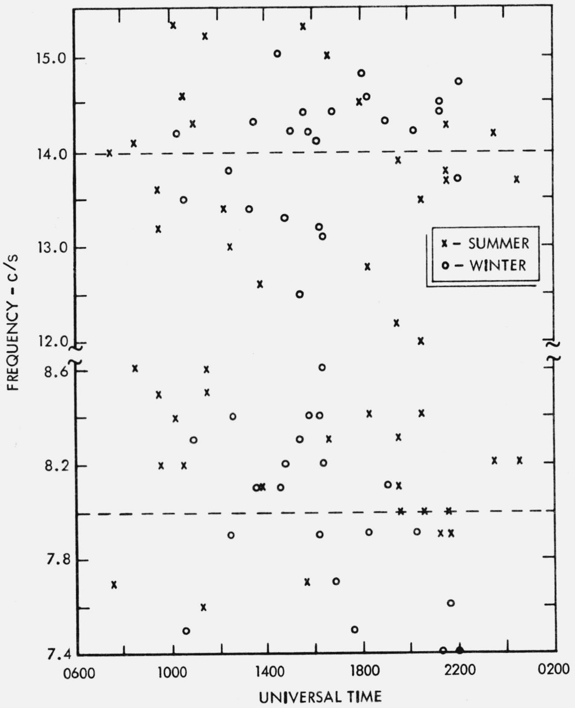

FIGURE 16. *Diurnal frequency variations measured by Rycroft.*

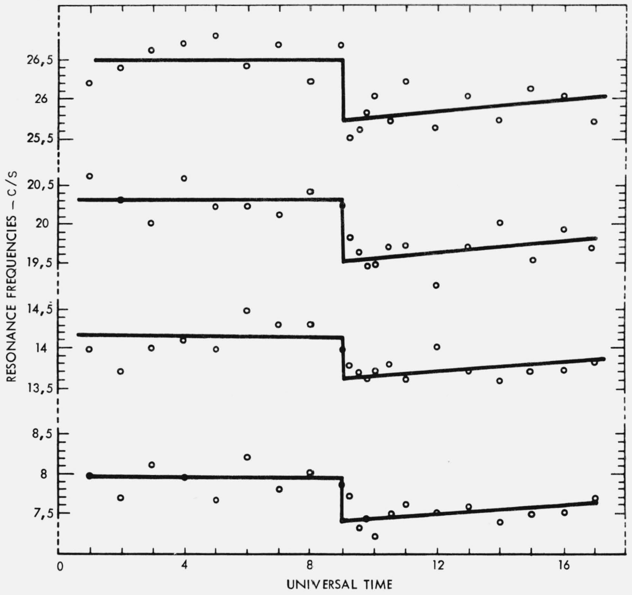

FIGURE 17. *Nuclear effects on earth-ionosphere cavity resonances.* Measurements by Gendrin and Stefant.

A high altitude nuclear explosion has been shown to affect the earth-to-ionosphere cavity resonances by simultaneously lowering all the resonance frequencies [Gendrin and Stefant, 1962a and b; Balser and Wagner, 1963]. Tepley et al., [1963] noted also an increase of signal strength for observations near the conjugate point of the explosion. The lowering of resonance frequency shown in figure 17 has been attributed to worldwide lowering of the effective ionosphere in a model of a single layer isotropic ionosphere [Gendrin and Stefant, 1962b]. The depression of the resonance frequency can be also explained by assuming an exponential daytime ionosphere to be effective around the globe [Row, 1964, private communication]. As an illustration the daytime resonance frequencies of table 1 compare with the measured resonance frequencies of figure 17. There are VLF observations [Zmuda et al, 1963] that can be explained by a lowering (or increasing electron density) of the *D*-region boundary. Brady et al., [1964] interpreted VLF diurnal phase shifts to show that some enhanced *D*-region ionization persists for several days following the event.

The lowering of the resonance frequency following a nuclear explosion has been attributed by Chapman and Jones [1964a] in their two-layer ionosphere model solely to a decreasing conductivity of the *E*-region.

After measuring a change of the resonance frequencies following a nuclear explosion, it is possible to advance simple ionosphere models for explaining a particular change. However, no attempt has been reported to predict resonance shifts for different nuclear yields and detonation altitudes. This rather complex problem requires a quantitative evaluation of the various nuclear mechanisms that may lead to ionosphere perturbations. If such information is available, the computation of the resonance shifts is relatively simple. It would be also of interest to investigate the effects of sudden ionosphere disturbances (SID) and to discriminate between SID's and nuclear effects.

The resonant frequency changes can be considered more accurately with nonuniform models of the propagation geometry. A perturbation method [Wait, 1964b] or numerical techniques [Madden and Thompson, 1964] have been used for solving such problems.

Madden and Thompson [1964] compute the local surface impedance and propagation constant for a uniform cylindrical shell between the anisotropic ionosphere and the earth using matrix multiplication techniques. There is a smooth variation of the parameters between polar and equatorial regions and also between day and night hemispheres. These local surface impedances and propagation constants are assumed to characterize a spherical transmission line of nonuniform parameters. The resonance frequencies and Q factors are computed numerically using a lumped parameter approximation of the two-dimensional transmission line. This model has been applied to explain the diurnal frequency variations and also the frequency changes due to a nuclear explosion.

7. Areas of Future Work

There are numerous observations of earth-ionosphere cavity resonances and existing ionosphere and source models account for most observed characteristics like the resonance frequency, Q factors, shape of the noise spectra, and diurnal variations of the received power.

Future work appears to be required in a systematic study of diurnal and seasonal amplitude and frequency variations of resonances. These changes should also be correlated with ionospheric disturbances. The parameters of the nighttime ionosphere require also a future clarification. The variations of the ionosphere parameters and the variations of the magnetic field vector along the surface of the earth should be incorporated in future calculations [Wait, 1964b; Madden and Thompson, 1964]. Much work remains to be done for assessing nuclear effects on the earth ionosphere resonance and for discriminating between lower level nuclear and sudden ionospheric disturbances.

The work of Sylvania reported in this paper has been supported principally by the Office of Naval Research under Contract Nonr 3185(00).

8. Appendix. Q Factors

The basic definition of the Q factor of a cavity with lossy walls is

$$\frac{1}{Q_i}=\frac{\int\int \mathbf{E}\times\mathbf{H}^*\cdot\mathbf{ds}}{\frac{\omega\epsilon_0}{2}\int\int\int \mathbf{E}\cdot\mathbf{E}^*dv+\frac{\omega\mu_0}{2}\int\int\int \mathbf{H}\cdot\mathbf{H}^*dv} \tag{14}$$

where the surface integral is extended over the cavity walls and the volume integral covers the inside of the cavity. The ground surface is assumed to be a perfect conductor and E_θ is related to H_ϕ at the ionospheric boundary by the surface impedance Z_s as $E_\theta=Z_sH_\phi$. However E_θ is assumed to be small relative to E_r for vertically polarized waves. Equation (14) is rewritten as

$$\frac{1}{Q_i}=\frac{2\int\int \mathrm{Re}Z_s|H_\phi|^2(a+h)^2\sin\theta d\theta d\phi}{\omega\int\int\int[\epsilon_0|E_r|^2+\mu_0|H_\phi|^2]r^2dr\sin\theta d\theta d\phi} \tag{15}$$

$$\approx\frac{2\mathrm{Re}Z_s}{\omega h}\frac{\int|H_\phi|^2\sin\theta d\theta}{\int[\epsilon_0|E_r|^2+\mu_0|H_\phi|^2]\sin\theta d\theta} \tag{16}$$

where a is the radius of earth, h is the ionospheric height and where the cavity is assumed to be uniform. For excitation by a radial electric dipole of moment Idr the field component E_r and H_ϕ follow from (21), (61), and (62) of Galejs [1964a] as

$$E_r=\frac{iIdr}{4\pi h\omega\epsilon a^2}\frac{n(n+1)(2n+1)}{D_n}P_n(\cos\theta) \tag{17}$$

$$H_\phi=-\frac{Idr}{4\pi ha}\frac{(2n+1)}{D_n}\frac{\partial}{\partial\theta}P_n(\cos\theta) \tag{18}$$

with $D_n=n(n+1)-\nu(\nu+1)$. Substituting (17) and (18) in (16) and evaluating the integrals gives

$$\frac{1}{Q_i}=\frac{2\mathrm{Re}Z_s}{\omega\mu_o h\left[\frac{n(n+1)}{(k_0a)^2}+1\right]} \tag{19}$$

where $k_0=\omega\sqrt{\mu_0\epsilon_0}$. From the approximate modal equation

$$S=\sqrt{1+\frac{iZ_s}{\omega\mu_0h}} \tag{20}$$

it follows that

$$2\ \mathrm{Re}S\ \mathrm{Im}S=\frac{\mathrm{Re}Z_s}{\omega\mu_0h}\cdot \tag{21}$$

Applying (21) and the resonance condition

$$n(n+1)\approx(k_0a\ \mathrm{Re}S)^2 \tag{22}$$

(19) simplifies to

$$\frac{1}{Q_i}=\frac{4\ \mathrm{Re}S\ \mathrm{Im}S}{(\mathrm{Re}S)^2+1} \tag{23}$$

which was listed as (4). When considering the differences of E_r, H_ϕ, Z_s, and h between the day and night hemispheres it follows that

$$\frac{1}{Q_i}\approx\frac{2[\mathrm{Re}S\ \mathrm{Im}S|_{\mathrm{day}}+\mathrm{Re}S\ \mathrm{Im}S|_{\mathrm{night}}]}{(\mathrm{Re}S|_{\mathrm{avg}})^2+1}\,. \tag{24}$$

The form (5) or (6) is obtained by neglecting the E integral or H integral, and by doubling the value of the H integral or E integral in (14).

(57) **ABSTRACT**

A system for the recovery and use of the electrostatic charge present in the atmosphere during storms generated by lightning, transforming natural energy into electrical energy useful for consumption, and providing the necessary protection for lives and property against electro-atmospheric phenomena, has an ecological lightning conductor, an electrical conductor connected by one end to the low-frequency electrode of the lightning conductor, and an enhanced intelligent earth wire, whereto the conductor is joined by its other end. The conductor includes a series of probes and magnetic field detectors which will send information to the microprocessor and from there to the mainframe computer. The control device allows regulation of the earth resistance, thereby generating more or less charge, diverting the energy to the accumulators or to earth through dissipator electrodes.

SYSTEM FOR RECOVERING AND USING THE ELECTROSTATIC CHARGE GENERATED BY LIGHTNING

CROSS-REFERENCE TO RELATED APPLICATION

[0001] The invention described and claimed hereinbelow is also described in Spanish Patent Application ES 2009 01924 filed on Sep. 29, 2009. This Spanish Patent Application, whose subject matter is incorporated here by reference, provides the basis for a claim of priority of invention under 35 U.S.C. 119(a)-(d)

BACKGROUND OF THE INVENTION

[0002] The present invention relates to a system which allows the recovery and use of the electrostatic charge present in the atmosphere during storms which generates lightning, thereby achieving the transformation of natural energy into electrical energy useful for domestic and industrial consumption, while providing essential and adequate protection to persons, animals and property against the aforementioned atmospheric electrical phenomena.

[0003] Different technical and scientific arguments relative to the effective application of the system that is the object of this invention will be explained in detail in this description, in addition to describing the elements that compose the aforementioned system.

[0004] During an atmospheric storm formation process, variable electrical fields appear which are responsible for the generation and appearance of lightning, which are discharges between the ground and the atmosphere. As a result of the generation of electrical charges within the cloud, the atmosphere increases its electrical potential, inducing a variable ground voltage.

[0005] It has been scientifically proven that if this ground voltage is controlled, the current flowing through the ground can also be controlled, thereby adequately leveraging the full potential of this energy.

[0006] This will primarily avoid the electrical saturation of that area, which could call, excite or create a lightning bolt therein and, secondly, this energy may be accumulated in the most adequate manner.

[0007] This process for recovering energy from the atmosphere is carried out before and during the first phase of the generation of lightning charges. The effect of attenuating the electrical field of the atmosphere causes the disappearance of the lightning discharge to ground, on not having sufficient potential for formation thereof, thereby allowing prevention and protecting persons, animals and property.

[0008] Widely known are the experiments and achievements of Benjamin Franklin in the 18th century, inventor of the passive lightning conductor equipped with a priming device or those developed subsequently using the "multipoint" system, the action of which is based on ionisation and excitation, constant or by impulses, of the electro-atmospheric field in order to capture the lightning discharge.

[0009] Mention must be made of radioactive lightning conductors, currently in disuse for evident safety reasons due to radiation hazard; likewise, other devices based on the filtration of high frequencies and harmonic components are also known to exist, equipped with two or more external electrical connections and having different components such as coils, resistors and condensers, duly connected and having the necessary siliceous sand for absorbing the thermal inertia produced when the system functions as a whole.

[0010] Reference is made herein to patent of invention P 200202884/2, by the same inventors, which relates to a deionising lightning conductor of electrostatic charge, based on three insulators equipped with a variable noble gas dielectric in its interior.

[0011] According to the data provided by the world meteorological detection system, more than four thousand storms form in the Earth's atmosphere every day, which generate around eight million lightning bolts.

[0012] The phenomenon called "lightning" is the electrical reaction caused by the saturation of electrostatic charges generated by the progressive accumulation of an electric field between the ground and the cloud, during the activation of a typical storm.

[0013] This phenomenon is randomly present as of an electro-atmospheric potential of 10/45 kV. It is generated between two points of attraction of different polarity and same potential for the purpose of compensating the saturation of the electrostatic charge. Lightning charge density is proportional to the saturation of the electrostatic charge of the area: the higher the charge density, the higher the risk of generating a tracker or "leader" and, subsequently, a lightning discharge.

[0014] Lightning charge intensity is variable, depending on the critical moment when the resistance in the air between the two transfer points break down; it will also be influenced by serially exposed materials such as soils, rocks, wood, iron or other metals, lightning conductors, earth wires, etc. A lightning bolt can transport an average charge of 20 GW of power per second, equivalent to one hundred million ordinary incandescent light bulbs.

[0015] This electrical phenomenon is represented in the form of an electronic shadow, which determines the elements that will be affected by charge exchange.

[0016] Studies carried out on the electro-atmospheric field at ground level reveal that charge distribution during the generation of the high-voltage field is not static but rather dynamic, on being randomly formed and generating the moving tracker or leader and different geographical points at the same time. The intensity and location of this electronic shadow can change radically and affect the low or lateral areas of high structures or buildings.

[0017] The behavioural study of a conventional pointed lightning conductor has demonstrated that they generate, to a greater or lesser extent, electromagnetic effects in the installations themselves, as well as in neighbouring installations, upon capturing the lightning bolt. In the case of ionising lightning conductors, accidents frequently occur for this reason.

[0018] Recently, enhancements made in electrostatic charge deionising lightning conductors through the application and incorporation of new technologies, such as a special cable adaptable to different forms of energy transport, eliminates causes of accidents and improves the reliability of the facilities, in addition to acting within an ecological electrical environment free of electromagnetic interferences.

SUMMARY OF THE PRESENT INVENTION

[0019] Accordingly, it is an object of the present invention to provide a new system which allows recovering and using the electrostatic charge generated by lightening and provides for highly advantageous results.

[0020] In keeping with these objects this system allows to cover all levels of electrical risk, diversity in the type and polarity of lightning bolts for any type of structure. It is an individual and collective protection system which bases its operating principle on the orderly transformation of ions flowing in a current, and is useful for working at low voltages and previously be derived to an accumulation area.

[0021] The system is composed of an external electrode acting as an ecological lightning conductor, an electric conductor, designed and calculated for a wide range of frequencies, and having anti-corrosive protection and an intelligent earth wire, complemented by energy accumulators and dissipator electrodes, capable of deriving all current leakage to earth, all of said components being controlled by a microprocessor which manages the energy as it appears, controlling its intensity, as well as the charge of the aforementioned accumulators for subsequent consumption.

[0022] The system also incorporates an alarm-based alert device, both private and public, for occupational risk prevention management against lightning risk.

[0023] At meteorological level, the system allows data to be obtained relative to the behaviour of the electric field, temperatures, atmospheric pressure, humidity and quantity of discharges.

[0024] The invention being described incorporates magnetic field detectors and detectors for controlling earth leakage current intensity, for subsequent analysis thereof and the consequent alarms. These detectors send the information to the microprocessor, upon recording the abrupt magnetic field variations.

[0025] The deionisation system of the lightning conductor itself facilitates the appearance of small currents in the earth wire, where charges are intelligently accumulated for subsequent use thereof. Depending on the intensity of the natural earth electric field, the ecological lightning conductor system generates the appearance of an earth leakage current which passes through the electrical conductor from the lightning conductor, strictly speaking, to the earth wire. The automatic control system regulates earth resistance in order to generate more or less charge and divert energy to the accumulators or to the enhanced intelligent earth wire.

[0026] The intelligent earth wire incorporates an electronic system which automatically regulates its own electrical resistance with reference to the physical earth. This control system allows controlled energy transfer, maintaining a resistance of less than 5 ohms in the earth installation during the four seasons of the year and varying, as required, the electrical conductivity of the physical earth and its humidity in order to facilitate or stop leakage currents.

[0027] The intelligent earth wire consists of special electrodes, according to the type of soil and/or terrain, aimed at facilitating current leakage and avoiding corrosion of the metals. These electrodes are installed conveniently protected against the aggressiveness of any chemical or electrochemical reaction.

[0028] The novel features which are considered as characteristic for the present invention are set forth in particular in the appended claims. The invention itself, however, both as to its construction and its method of operation, together with additional objects and advantages thereof, will be best understood from the following description of specific embodiments when read in connection with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

[0029] FIG. **1** is a longitudinal diagram of the system in accordance with the present invention, illustrating the layout of the different components thereof;

[0030] FIG. **2** shows an outer view of the ecological lightning conductor of the inventive system; and

[0031] FIG. **3** is a complementary view of the preceding figure, showing a fully sectional view of the lightning conductor of the inventive system.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0032] A system for recovering and using the electrostatic charge generated by the lightning of the present invention includes an ecological lightning conductor **1**, disposed on a mast **2**, which is installed at the highest point of the existing structure by means of adequate bearings or on a newly built tower, an electrical conductor **3** and an intelligent earth wire **4**.

[0033] The electrical conductor **3** is connected by one end to the mast or low electrical resistance electrode **5** of the lightning conductor **1**, and connected to the intelligent earth wire **4** by the other end, said conductor incorporating a series of probes **6** and magnetic field detectors **7** that will send information to the microprocessor **8**.

[0034] These data, recorded by the microprocessor **8**, are sent to a mainframe computer **9** where they are processed, being immediately displayed on a screen or sent to an "Internet"-type data transport network.

[0035] The intelligent earth wire **4** is equipped with a control device **10** which will analyse, in real time, the earth current leakages, sending the data to the aforementioned mainframe computer **9**. Depending on the intensity of the leakage, the system will manage the information, generating alarms or modifying the processes for sending current to the energy accumulators **11**, disposed next to the intelligent earth wire **4**. This earth wire **4** also has dissipator electrodes **12** at ground level.

[0036] The ecological lightning conductor **1** has a toroidal-shaped body **13**, closed by its upper part by an upper frame **14** and completed by a lower frame **15** whereto, in the central appendix **16** of its lower part, is fixed to the mast or low electrical resistance electrode **5**.

[0037] The dielectric product, which is essential for the object to act as a lightning conductor in itself, is disposed in the interior of the toroidal body **13** of the ecological lightning conductor. The dielectric product can be of noble gas.

[0038] The previously described characteristics of the ecological lightning conductor confer the quality of deionising lightning conductor to this system component, which allows the appearance, as mentioned earlier, of small currents in the intelligent earth wire **4**, where the charges are accumulated for their subsequent consumption in the energy accumulators **11**.

[0039] During a storm process, a high-voltage field is generated at ground level which is proportional to the charge of the cloud and the distance that separates it from the ground.

[0040] As of a certain magnitude of the natural electric field on the physical earth, the equipotential installation of earth wires of the system facilitates transfer of the charges through the electrical conductor **3**, charges which, regardless of their polarity, are concentrated on the mast or lower electrode **5** of the lightning conductor **1**, disposed at the highest point of the installation that configures the system, which is connected to the earth wire by means of the electrical conductor **3**. The current that circulates through the lightning conductor-conductor-earth wire system is proportional to the charge within the cloud.

[0041] The low resistance of this mast or lower electrode **5** of the lightning conductor **1**, facilitates the capture of opposing charges in the electrode or upper body **13**. During this energy transfer process, a small current flow takes place between the cathode and anode in the interior of the lightning conductor, in the direction of the current flow.

[0042] The resulting effect causes the appearance of a weak leakage current that derives to the electrical earth wiring of the installation, which is controlled by a microprocessor **8** which, in turn, causes current shunting to an accumulation system **11** or to dissipator electrodes **12** at ground level.

[0043] The evolution of the electro-atmospheric phenomenon is recorded in a database by means of electric probes **6** installed in the electrical conductor **3**, disposed between the lightning conductor **1** and intelligent earth wire **4**, and magnetic field detectors **7**. The data are stored, in real time, in a microprocessor **8** thanks to the transfer of data from the probes **6** to the mainframe computer **9**, via radio or conductor. These data may be viewed on a PC screen and statistics calculated, both real time and historical, for the purpose of carrying out electromagnetic and electrical prevention studies.

[0044] The novel technology of the system that is the object of the invention, and which is being described, allows optimisation of industrial process management and enhancement of personal electrical safety.

[0045] Depending on the intensity of the current that flows through the conductor **3** towards the earth wire **4**, high electric field alarms may be generated, consequently alerting of the risk of electrical storm in the area, with lightning activity.

[0046] Having sufficiently described the characteristics of the system that is the object of the present invention, we must point out that any variation in dimensions, shapes, types of materials and layout of the different components shall not alter the essentiality of the invention and may be necessary according to the protection requirements of the desired area, based on factors such as the geographical area, environmental context and dimensions.

[0047] It will be understood that each of the elements described above, or two or more together, may also find a useful application in other types of constructions differing from the types described above.

[0048] While the invention has been illustrated and described as embodied in a system for recovering and using the electrostática charge generated by ligntening, it is not intended to be limited to the details shown, since various modifications and structural changes may be made without departing in any way from the spirit of the present invention.

[0049] Without further analysis, the foregoing will so fully reveal the gist of the present invention that others can, by applying current knowledge, readily adapt it for various applications without omitting features that, from the standpoint of prior art, fairly constitute essential characteristics of the generic or specific aspects of this invention.

What is claimed as new and desired to be protected by Letters Patent is set forth in the appended claims.

1. A system for recovering and using an electrostatic charge generated by lightning and being present in an atmosphere during storms for transforming a natural energy into electrical energy and providing a necessary protection to persons, animals and property, the system comprising components including an element selected from the group consisting of an external electrode and an ecological lightning conductor, a mast fixing said electrode, an intelligent earth wire, an electrical conductor joining said element to said intelligent earth wire, energy accumulators, dissipation electrodes, electric probes, magnetic field detectors, and a microprocessor controlling all the components of the system and transferring data to a mainframe computer.

2. A system for recovering and using the electrostatic charge as defined in claim **1**, wherein said ecological lightning conductor has a toroidal-shaped body housing containing a dielectric product, an upper frame closing said body, a lower frame completing said body, and a lower central appendix in which a member selected from a group consisting of said mast and a low electrical resistance electrode is fixed.

3. A system for recovering and using the electrostatic charge as defined in claim **2**, wherein said toroidal-shaped boyd of said ecological lightening conductor contains a noble gas.

4. A system for recovering and using the electrostatic charge as defined in claim **1**, wherein said electrical conductor has one end connected to a member selected from the group consisting of a mast and an electrode and is designed for a wide range of frequencies and has adequate anti-corrosion protection, said electrical conductor also having another end joined to said intelligent earth wire, said electrical conductor incorporating said electric probes and said magnetic field detectors.

5. A system for recovering and using the electrostatic charge as defined in claim **1**, wherein said intelligent earth wire is provided with disipator electrodes at a ground level according to a type of a component selected from the group consisting of soil, terrain and both.

6. A system for recovering and using the electrostatic charge as defined in claim **1**, further comprising a control device analyzing earth current leakages in real time and sending data to the mainframe computer, generating according to a leakage intensity, alarms or modifying a process for sending current to said accumulators.

LIGHTNING PROTECTION SYSTEM AND METHOD

Application filed July 26, 1927. Serial No. 208,536.

This invention relates to lightning protection systems and, also, to lightning protection methods.

In general, an object of the invention is to protect particular areas or structures against being struck by lightning.

More particularly, an object of the invention is to provide a system and method whereby the point or points for receiving the lightning strokes are predetermined.

Another object is to make provision for taking care of the consequential secondary discharges.

Heretofore, it has been a practice for protecting certain areas and structures from lightning strokes, to provide towers, masts and network, singly or enclosing said areas or structures, thus providing a multiplicity of points in the expectation that one or more of said points would receive the lightning stroke in event of the stroke occurring in the vicinity of the area or structure thus protected, thus diverting the lightning stroke from said area or structure. Protection against lightning might possibly be afforded in this manner if it were practicable to erect towers in sufficient number and of sufficient height or to provide metallic enclosures of a type that would insure immunity for the enclosed area or structure against lightning strokes. This, however, is not, generally, feasible economically. Accordingly, another object of the present invention is to afford adequate protection in an economical and practicable manner.

In order to more clearly understand the invention, let it be assumed that there is a cloud sufficiently charged with electricity at a considerable height above the earth, imposing by its influence, an equal charge of electricity of opposite sign on the earth. The result will be a potential difference between the cloud and the earth, the presence of which is manifested in the form of an electrostatic atmospheric potential gradient. As a further result, there will be tendency toward equalization of this potential gradient through the medium of whatever conduction may exist across or through the dielectric or dielectrics separating the charged bodies which, in this instance, are the cloud and the earth.

As the cloud approaches the earth, or as the charge on the cloud increases, the potential gradient becomes steeper and the air intervening between the cloud and the earth becomes subjected to a greater electrostatic stress. The greater this stress the greater will be the tendency of the dielectric to break down and become to a greater or less degree conductive of electric current. In this case, conductivity is primarily due to ionization, probably the ionization of collision, when electrons are pulled from the atoms of the dielectric by the more or less intense strain exerted by the potential gradient. The theoretical explanation of what occurs implies a breaking up of the atoms of the dielectric into electrons and protons which, under the influence of the potential gradient, are drawn, respectively, toward the positively charged body and the negatively charged body.

Other factors being equal, the conduction across a stratum of air will be in direct ratio to the degree of ionization which, in turn, is largely dependent on the potential gradient. Therefore, when two electrically charged bodies of opposite sign exist and there is a tendency toward equalization of potential between them, under such conditions a reduction in the potential difference may take the form of a visible phenomena, when the so-termed ionization potential of the dielectric has been reached. This will be visibly indicated by the formation of corona and under slightly higher potentials, by the formation of streamers, these manifestations generally preceding a more or less complete breakdown of the dielectric, particularly under conditions of increasing or extremely high potential gradient. Under these conditions it is probable that the ionization of collision is supplemented by ionization due to increase in temperature, since the increased molecular activity causes more electrons to give up their energy in the form of heat which results from collision. The effects are undoubtedly cumulative when the potential gradient is sufficiently high.

The rate at which equalization of potential occurs between an electrically charged cloud and the earth depends on the steepness of the potential gradient and the character of the dielectric and, under a sufficiently steep potential gradient, every projecting point on the surface of the earth, such as blades of grass and leaves on the trees, in the vicinity, will have an electric discharge ranging from an infinitesimal amount to an amount that results in visible corona and streamers. If the cloud attains sufficient electric charge and has sufficient capacity, to make it a potential source of lightning strokes, some path of ionization or breakdown of the dielectric may occur between the cloud and the earth and along this highly conducting path, the current flow which constitutes a lightning stroke will take place. The earth end of this path of ionization will be at some point which, under the existing potential gradient, has a greater discharge, or ionizing influence, than any other nearby point. This is because the power of ionization is the result of the introduction into the space under stress of a number of free electrons (created through ionization) with a consequent tendency to render that particular portion of the space relatively conducting by moving under the influence of the potential gradient and tending to leave a more or less ionized path, and, therefore, one that is more or less conducting of electric current. It follows from this that the ground point first furnishing ionization or electrons in sufficient degree, will be the point from which the path of ionization will start and, if the path of ionization be then completed to the charged cloud, said point will be the one where lightning will strike the earth, all other conditions being the same.

In nature, there are so many variables which influence the behavior and occurrence of lightning strokes that it is manifestly impossible to predetermine and locate every danger point with a view toward avoiding the hazard at said point and in the area adjacent to said point. It is an object of the present invention to artificially create, at will, and at any desired point, an ionized area corresponding to the ionized area at the earth end or point of the lightning stroke so that, by locating this point removed from a particular structure or area, the same will be protected or rendered immune against lightning discharges, any discharge in that particular area being taken by the specially prepared point.

The potential of metallic objects or bodies on the earth is that of the earth and, under the influence of electrical disturbances, a considerable electric charge may be carried to a point considerably above the surface of the earth. As long as the potential gradient remains unchanged, this elevated charge will be in equilibrium and, accordingly, no hazard is present from such conditions; but, in the event of a sudden change in the potential gradient following a lightning discharge, there is a tremendous surge of current from the metallic objects or bodies to the earth. This surge is composed of the elevated charges, the potential of which, when the gradient is reduced, is above that of the earth. If an unbroken path, such as is formed by a metallic conductor of ample capacity, exists from the elevated charges to the earth, the charges, suddenly released, are carried harmlessly to the earth along said path and the electrical equilibrium is again restored. However, any break in the conducting path or lack of capacity of the metallic conductor to properly take care of the current flow will result in a bridging of the gap, resulting from the break in the conductor, by the electric current and the consequent formation of an arc across said gap, thus producing a serious fire hazard.

These electric charges, which take up their position under the stress of a potential gradient are known as bound charges and, when released, following lightning strokes, constitute secondary electric surges which are particularly hazardous in the presence of inflammable liquids and gases. The roof of a reservoir or tank used for the storage of petroleum is a typical example of hazard due to secondary electric discharges or surges. Accordingly, it is an object of this invention to provide a path of electric current conductive material of a capacity to handle the maximum surges to the earth and to make this path a part of the structure to be protected.

In the system I at present propose to employ, there is an electric device for producing corona, brush, streamer, or other high frequency discharges from the top of suitable towers, masts or other elevated structures grounded to the earth, to provide a path along which lightning discharges will flow, and included in the system is a grounded metallic network or grid having a capacity sufficient to relieve the area or structure being protected from any bound electrical charge released by a sudden decrease in the atmospheric potential gradient, such as may follow a stroke of lightning in the vicinity of said area or structure. This grounded metallic network is in all instances placed directly on the surface of and in contact with any roof, tank roof, reservoir roof or other structure which may under a high gradient be the seat of bound charges which upon release may form a secondary surge to ground.

The accompanying drawings illustrate a system constructed in accordance with the provisions of this invention and capable of operating to perform the method in accordance with the invention, the drawings being more or less diagrammatic.

Figure 1 is a view of a lightning protection system embodying the invention.

Figure 2 is an enlarged view, mainly in

section, from the line indicated by 2—2, Figure 1.

Figure 3 is an enlarged plan view of the left portion of Figure 1 showing the reservoir and the elements adjacent thereto.

Figure 4 is a plan showing in detail the base of one of the masts, together with the guy wires and grounding wires.

Figure 5 is a plan view of one of the masts, together with its guy wires and the anchors for said wires, the mast being shown in section.

Figure 6 is an enlarged view of the ionizing apparatus, the housing being shown in section.

Figure 7 is a wiring diagram of the wiring of the ionizing apparatus.

Figure 8 is a diagram of electrical connections.

Referring to the drawings, the area or structure to be protected against lightning strokes may be, for example, a tank farm of the character used for the storage of petroleum and its products. In Figure 3, two tanks or reservoirs of such tank farm are indicated at 11 and on each of them is a metallic network or grid 12 for conducting to ground the bound charges that may exist on the reservoir roof. As indicated in Figure 2 the grids 12 may be metallically bonded to the reservoir roofs 13 as indicated at 14 so that, under the influence of an unbalanced potential, any secondary electrical discharges will be carried to the earth, without arcing, by grounds 15 from the grids. Said grounds may be pipes. The grids are connected to the pipes by wires 16.

Now referring, more particularly, to Figure 8, there is provided a manually controlled switch 17 connecting with a source of commercial or other electric current, preferably at a location that is remote from the area and structure that are to be protected. The manually operated switch 17 is connected by wires 18, 19 to remote control switches 20. 21 indicates a line protector for grounding transients and lightning surges that may occur in the wires 18, 19. The remote control switches 20 are connected by wires 22, 23 to a high frequency, high voltage generator or resonance coil 24 which, when in operation, produces the electrical discharge for ionization. The generator 24 is grounded at 25 to the earth so that lightning discharges will be conducted to the earth.

In Figure 8 but one resonance coil or generator 24 is indicated, but, preferably, the upper end of each mast 40 will be provided with such coil or generator and this comprises a portion of the ionization apparatus which is illustrated, more or less diagrammatically in toto in Figure 6. Referring more particularly to said Figure 6 there is provided a base 26 mounted in a housing 27. The base 26 is of suitable electrical insulating material such as hard rubber, bakelite or the like. Mounted on the base 26 is a support 28 for primary winding 29. Also mounted on the base 26 is a cylinder 30 of suitable insulating material, such as hard rubber, bakelite or the like, and on said cylinder is a secondary winding 31. Connected to one end of the secondary winding 31 and projecting through the top of the housing 27 into the atmosphere is a vertical metal rod 32. The rod 32 is surmounted by a metal ball 33. The other end of the secondary winding 31 is connected to a point on the primary winding 29 and the secondary winding 31 is connected by a wire 34 to the ground 25 hereinbefore mentioned. Mounted in the housing 27 is a line-voltage transformer 35. The secondary winding 36 of the transmitter 35 connects with a spark gap 37 and also connects with the ground 25 and with a variable condenser 38 which, in turn, connects with the primary winding 29.

The housing 27 is constructed of suitable weather proof material and covers all elements of the ionizing apparatus excepting the ball 33 and a portion of the rod 32 and the housing may be connected to the mast, with which it is associated, by a pipe flange 39 which is secured to the bottom of the housing and which is threaded on to the upper end of the mast.

The above described system operates to perform the various operations of the method, as follows: Assuming that there are indications of an approaching storm or that a storm may eventually occur in the area or near the structure to be protected, the manually operated switch 17 will be closed, thus energizing the lines 18, 19 so as to operate the remote control switches 20. This connects the ionization apparatus with the source of power and renders the system operative for producing the desired effect on lightning discharges. The high frequency, high voltage generator operates to produce sufficient free electrons adjacent the ball 33 to insure that, if a path of ionization is even completed from the earth to a cloud in that area, the earth end of that path will be in the ionized zone surrounding the ball 33.

It is to be understood that the remote control switches may be dispensed with and the system put into and out of operative condition by manually operated switch or switches at the base of the mast or other supporting structure.

It is to be understood that the system above described may be modified in any suitable manner to suit local conditions.

It will appear from the foregoing that the methhod of protecting an area or structure against lightning involves the operation of producing a definite zone of relatively high ionization at a point or points removed from the area that is to be protected. The method also includes the operation of conducting to the earth from any elevated objects that may be in the protected area, the secondary electrical surge resulting from a lightning discharge in the vicinity.

It is to be particularly noted that in this system the metallic grid or network lies directly on the structure that is to be protected with no dielectric separating the grid and structure. Consequently, when the grid drains the charges to ground, following a lightning discharge in the vicinity, it drains from the structure to ground charges on the structure and, therefore, no fire hazard can exist there.

I claim:

1. The combination with a reservoir for inflammable substances, of a metallic grid in contact with and extending over said reservoir and electrically connected with the earth, an elevated structure at one side of the reservoir, and a means mounted on the elevated structure operable to artificially produce a higher ionized zone above the level of the grid than is producible in said zone by the natural charged condition of the earth, the last mentioned means being electrically connected with the earth.

2. The combination with a reservoir for inflammable substances, of a metallic grid resting on the roof of said reservoir in contact with and bonded thereto, means for electrically connecting the metallic grid with the earth, and means for artificially producing a measurably higher ionized zone at a point removed from the grid than is producible in said zone by the natural charged condition of the earth, the last mentioned means being electrically connected with the earth.

Signed at Ventura, Calif., this 5th day of July, 1927.

HAROLD L. BUMBAUGH.

The Amazing Motor That Draws Power from the Air

by

C.P. Gilmore & William J. Hawkins

Would you believe an electric motor made almost entirely of plastic? That can run on power transmitted through open air? And sneak free electricity right out of the earth's electrical field?

At the University of West Virgina we saw a laboratory full of such exotic devices spinning, humming, and buzzing away like a swarm of bees. They are electrostatic motors, run by charges similar to those that make your hair stand on end when you comb it on a cold winter's day.

Today, we use electromagnetic motors almost exclusively. but electrostatics have a lot of overlooked advantages. They're far lighter per horsepower than electromagnetics, can run at extremely high speeds, and are incredibly simple and foolproof in construction.

"And, in principle," maintains Dr Oleg Jefimenko, "they can do anything electromagnetic motors can do, and some things they can do better."

Jewel-like Plastic Motors.

Jefimenko puts on an impressive demonstration. He showed us motors that run on the voltage developed when you hold them in your hands and scuff across a carpet, and other heavier, more powerful ones that could do real work. Up on the roof of the University's physics building in a blowing snowstorm, he connected an electrostatic motor to a specially designed earth-field antenna. It twirled merrily from electric power drawn out of thin air.

These remarkable machines are almost unknown today. Yet the world's electric motor was an electrostatic. It was invented in 1748 by Benjamin Franklin.

Franklin's motor took advantage of the fact that like charges repel, unlike ones attract. He rigged a wagon-wheel-sized, horizontally mounted device with 30 glass spokes. On the end of each spike was a brass thimble. Two oppositely charged leyden jars -- high voltage capacitors -- were so placed that the thimbles on the rotating spokes barely missed the knobs on the jars (see photo).

As a thimble passed close to a jar, a spark leaped from knob to thimble. That deposited a like charge on the thimble, so they repelled each other. then, as the thimble approached the oppositely charged jar, it was attracted. As it passed this second jar, a spark jumped again, depositing a new charge, and the whole repulsion-attraction cycle began again.

In 1870, the German physicist J.C. Poggendorff built a motor so simple it's hard to see what makes it work. The entire motor, as pictured here, is a plastic disk (Poggendorff used glass) and two electrodes. The electrodes set up what physicists call a corona discharge; their sharp edges ionize air molecules that come in contact with them. These charged particles floating through the air charge the surface of the palstic disk nearby. Then the attraction-repulsion routine that Franklin used takes place.

A few papers on electrostatic motors have trickled out of the laboratories in recent years. But nobody really showed much interest until Dr Jefimenko came on the scene.

The Russian-born physicist was attending a class at the University of Gottingen one day shortly after World War II when the lecturer, a Prof. R.W. Pohl, displayed two yard-square metal plates mounted on the end of a pole. He stuck the device outside and flipped it 180 degrees. A galvanometer hooked to the plates jumped sharply.

"I could never forget that demonstration," said Jefimenko. "And I wondered why, if there is electricity in the air, you couldn't use it light a bulb or something."

Electricity Everywhere

The earth's electrical field has been known for centruries. Lightning and St Elmo's fire are the most dramatic manifestations of atmospheric electricity. But the field doesn't exist just in the vicinity of these events; it's everywhere.

The earth is an electrical conductor. So is the ionosphere, the layer of ionized gas about 70 kilometers over our heads. The air between is a rather poor insulator. Some mechanisms not yet explained constantly pumps large quantitites of charged particles into the air. The charged particles cause the electrical field that Jefimenko saw demonstrated. Although it varies widely, strength of the field averages 120 volts per meter.

You can measure this voltage with an earth-field antenna -- a wire with a sharp point at the top to start a corona, or with a bit of radioactive materials that ionizes the air in its immediate vicinity. near the earth, voltage is proportional to altitude; on an average day you might measure 1200 volts with a 10-meter antennas.

Over that past few years, aided by graduate-student Henry Fischbach-Nazario, Jefimenko designed advanced corona motors. With David K. Walker, he experimented with electret motors. An electret is an insulator with a permanent electrostatic charge. It produces a permanent electrostatic charge in the surrounding space, just as a magnet produces a permanent magnetic field. And like a magnet, it can be used to build a motor.

Jefimenko chose the electrostatic motor for his project because the earth-field antennas develop extremely high-voltage low-current power -- and unlike the electromagnetic motor -- that's exactly what it needs.

The Climactic Experiment

On the night of Sept. 29, 1970, Jefimenko and Walker strolled into an empty parking lot, and hiked a 24-foot pole painted day-glow orange into the sky. On the pole's end was a bit of radioactive material in a capsule connected to a wire. The experimenters hooked an electret motor to the antenna, and, as Jefimenko describes it, "the energy of the earth's electrical field was converted into continuous mechanical motion."

Two months later, they successfully operated operated a corona motor from electricity in the air.

Any Future In It?

Whether the earth's electrical field will ever be an important source of power is open to question. There are millions -- perhaps billions -- of kilowatts of electrical energy flowing into the earth constantly. Jefimenko thinks that earth-field antennas could be built to extract viable amounts of it.

But whether or not we tap this energy source, the electrostatic motor could become important on its own.

* In space or aviation, it's extreme light weight could be crucial. Jefimenko estimates that corona motors could deliver one horsepower for each 3 pounds of weight.

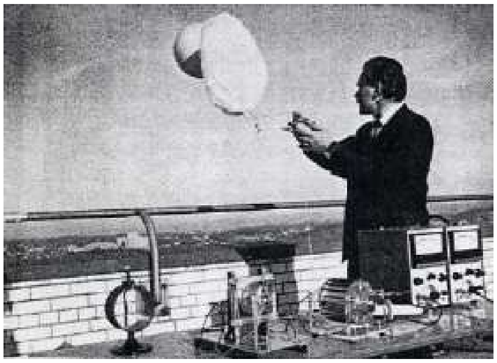
* They'd be valuable in laboratories where even the weakest magnetic field could upset an experiment.

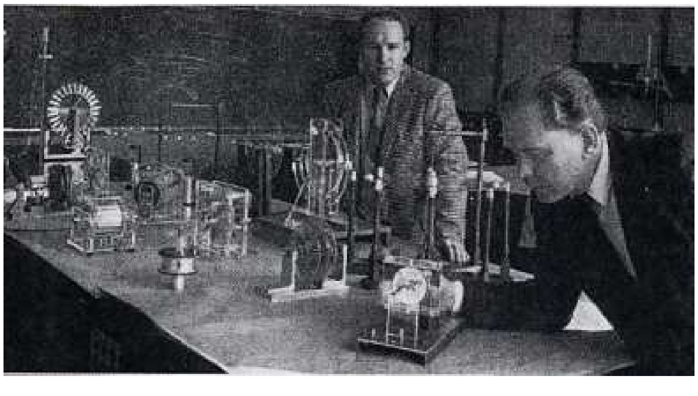
* Suspended on air bearings, they'd make good gyroscopes.

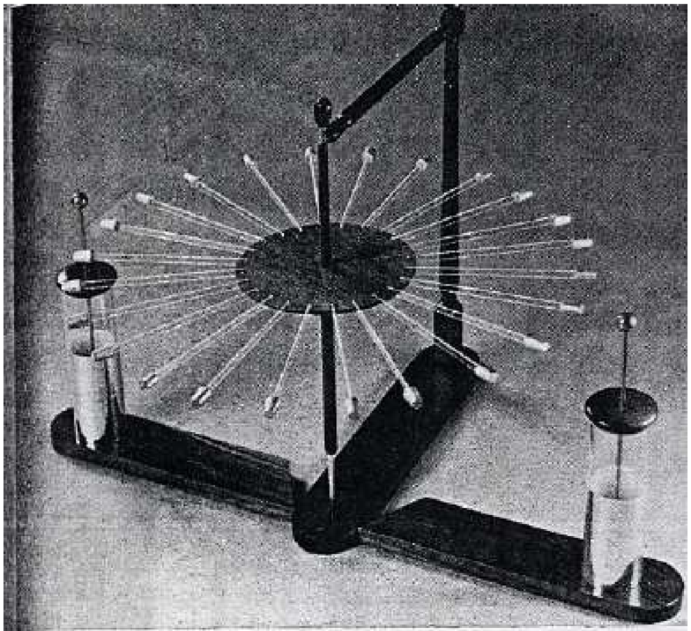
In a particularly spectacular experiment, Jefimenko turned on a Van de Graaff generator -- a device that creates a very-high-voltage field. About a yard away he placed a sharp-pointed corona antenna and connected it to an electrostatic motor. The rotor began to spin. The current was flowing from the generator through the air to where it was being picked up by the antenna.

The stunt had a serious purpose: The earth's field is greatest on mountaintops. Jefimenko would like to set up a large antenna in such a spot, then aim an ultraviolet laser beam at a receiving site miles away at ground level. The laser beam would ionize the air, creating an invisible conductor through apparently empty space.

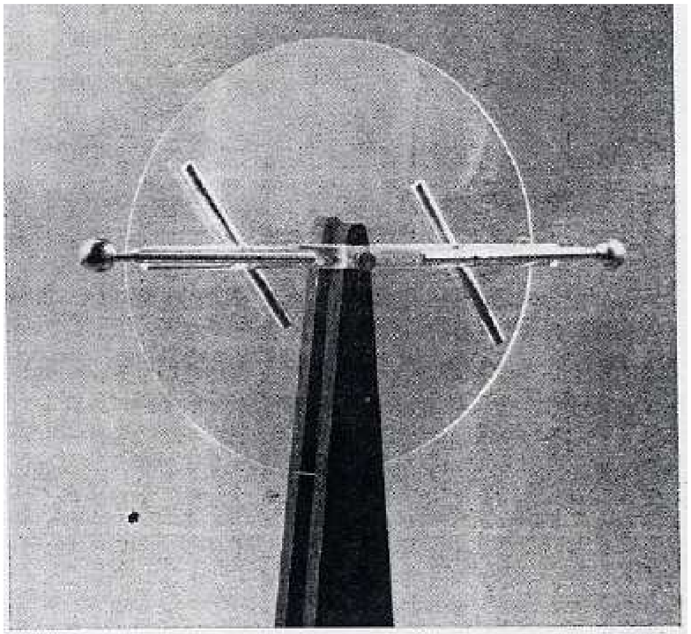
To be sure, many difficulties exist; and no one knows for sure whether we'll ever get useful amounts of power out of the air. But with thinking like that, Jefimenko's a hard man to ignore.



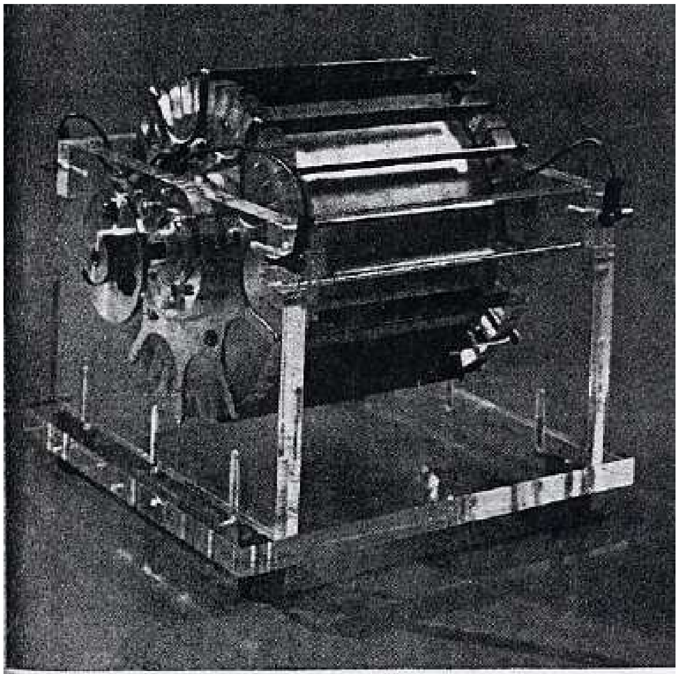




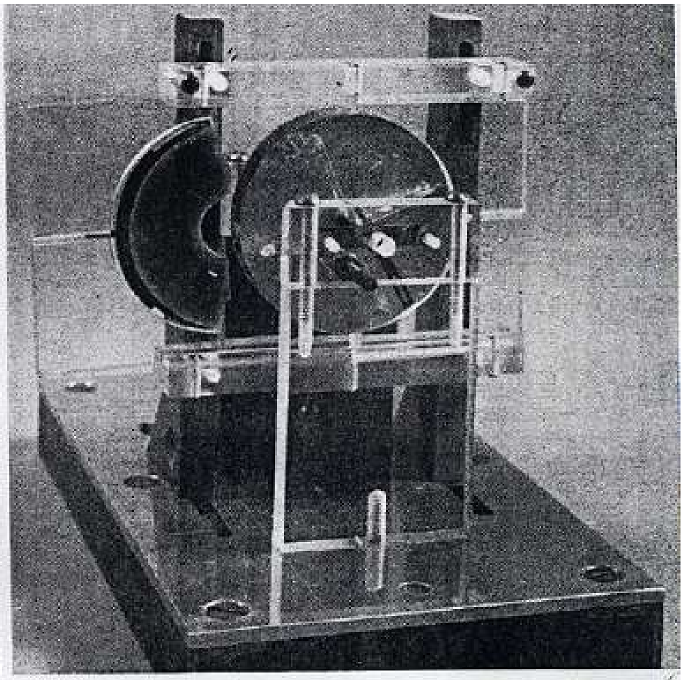
World's first electrostatic motor looked like this, according to Benjamin Franklin's description. Franklin said he'd use it to turn a roasting turkey, but there's no evidence that he did.



Simplest electrostatic motor ever designed was built by physicist J. C. Poggendorff. Two slanted electrodes spray charges onto disk, alternately repel and attract it to make it revolve.



Most efficient, most powerful electrostatic shown to date was designed by Dr. Oleg Jefimenko. It has multiple electrodes, cylindrical rotor, and develops a maximum of 70 watts of power.



Electret motor above turns on as little as 60 volts. It was the first to run on power from the earth's electrical field. Such motors can achieve extremely high speeds, and use little power

Electrostatic Motors You Can Build

by

C.P. Gilmore & William J. Hawkins

When we crank up the electrostatic motor at the top of this page, people always want to know what makes it run. It is mysterious -- there's nothing but a plastic disk and two strange electrodes. Yet there it is, spinning merrily.

In "The Amazing Motor That Draws Power From the Air", last month, we told about our visit to the laboratory of Dr Oleg Jefimenko at the University of West Virginia, who has designed and built a variety of these ingenious machines. now, as promised, we bring you details on how you can build your own electrostatic motor from simple materials.

The devices that you see here are corona-discharge motors. The sharp-pointed or knife-edge electrodes create a corona, which ionizes or charges the air particles floating by. These charged particles transfer their charge to the closest part of the plastic rotor and charge it up, just as you can charge your body by walking across a wool rug on a dry winter's day.

Once a spot on the rotor assumes a charge, it is repelled from the chargin electrode by electrostatic forces, and at the same time is attracted to the other electrode, which has an opposite charge. When the charged section of the rotor reaches the opposite electrode, another corona discharge reverses the polarity and starts the whole thing over again.

The Concept is Simple

And so are the motors. But that doesn't mean thery're easy to build. These motors run on millionths of a watt; they've got no power to waste turning stiff bearings or slightly misaligned rotors. So they must be built with watch-making precision.

They're made of acrylic sheet, rod, and tube stock -- Plexiglas and Lucite are two of the better-known brands. Acrylic cuts and works beautifully. Cut edges can be sanded so they have a white, frosted appearance that, in contrast with clear surfaces, gives your finished motor a sparkling, jewel-like appearance. If you like clear edges, you can buff them on a wheel and the whole thing becomes transparent.

Drill and tap the acrylic and assemble parts with machine screws. This allows for fine adjustment and alignment. Later, you can make the whole thing permanent by putting a little solvent along the joints. The solvent flows into the joint and fuses it permanently.

Details of framework, support and so on aren't important; change them if you like. but work with care if you want to avoid headaches. The Poggendorff motor looked simple; we slapped it together in a couple of hours, hooked up the power source -- and nothing happened. We gave it a few helpful spins by hand, but it wouldn't keep running.

The cure took about 3 hours. First, we noticed that the outer edge of the disk wobbled from side to side about 1/16 of an inch as the wheel revolved. So the rotor-electrode distance was constantly changing. There was a little play in the 1/4" hole we had drilled for the electrodes -- so they weren't lined up absolutely square with the disk. Then we noticed that the disk always stopped with one side down. The imbalance was only a fraction of an ounce -- but it was too much.

We drilled out the old hub and cemented in a new one -- this time, carefully. We lined up the electrodes -- precisely. Then, once more spinning the disk by hand, we added bit of masking tape until it was perfectly balanced. We connected the power -- and slowly... slowly... the disk began to turn. After about a minute, we clocked some turns with a watch and found it was spinning at 200 rpm. A moment later, we lost count. It was a great feeling.

Where Tolerances Are Brutal

We had even more trouble with the octagonal-window machine. When it wouldn't run and we turned the shaft by hand, we could feel the rotor dragging. We took it apart, felt all the surfaces on the rotor and the framework's insides and found a few bits of hardened cement, which we removed. We filed down all edges on the rotor adn the windows to make sure there were no beads or chips dragging.

The rotor and corner separators are made from the same sheet of 1/2" plastic, so rotor clearance is achieved by putting shims at the corners to hold the side plates slightly more than 1/2" apart. With the 1/16" shims we were using, we could see that the sides were slightly misaligned so the shaft was not being held at a true 90 degrees. We drilled slightly oversized holes in the corners of one side piece and carefully adjusted until the rotor was turning true in the slot. To give the motor more torque, we put a bead of cement along the outer edge of each aluminum-foil electrode to stop corona leakage. The motor ran.

Take A Giant Step

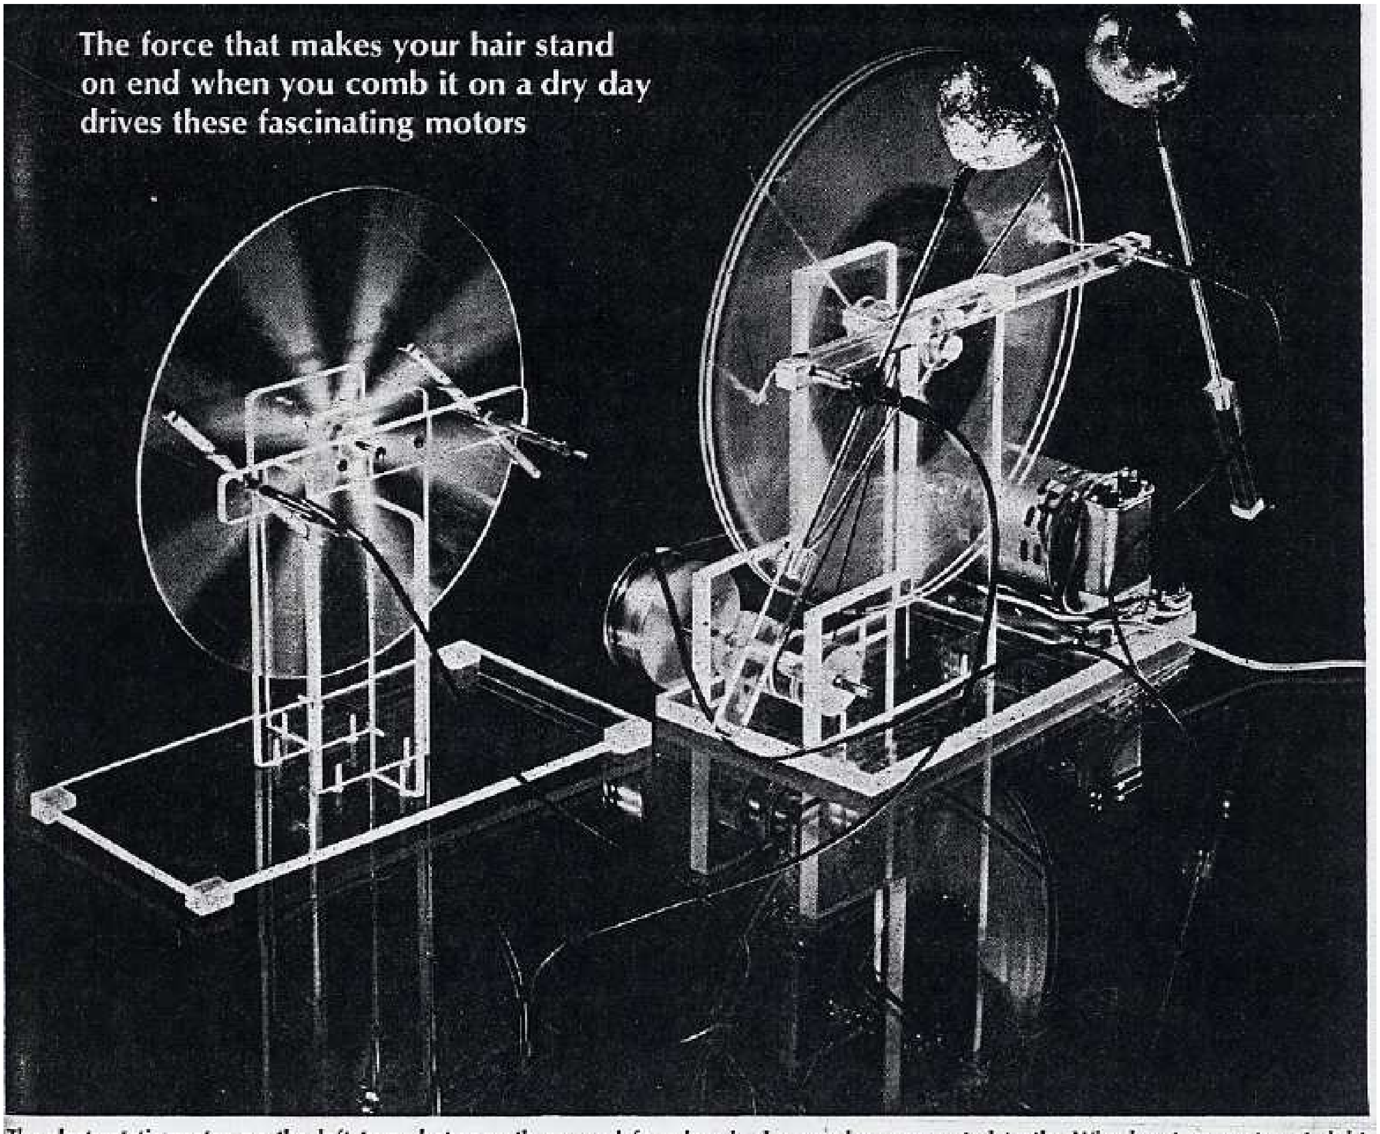
Once you've built these machines, why not design your own? Start with the Jefimenko 1/10 hp model (pictured) as a challenge. Then plan one from scratch. You can power your motors with a laboratory high-voltage supply, a Van de Graff generator, or a Wimhurst machine or any other high-voltage source. We've been running ours on the home-built Wimhurst machine shown in the photos. (If you don't want to build one, Wimhurst machiens are available from scientific supply houses such as Edmund Scientific).

The discharge globes are traditional for high-voltage machines. They aren't necessary, but they give a quick check on machine operation and a satifying arc when you move them within 1/2" of each other. Incidentally, that funny smell is ozone. But its concentration is too low to be harmful. The generator is safe, too. You can hold both electrodes in your hands and all you'll feel is a tingle. This particular generator, we estimate, puts out about 30,000 volts.

To make wiring simple, we used standard connectors on the Wimhurst collectors, and meter leads with regular banana plugs and alligator clips to hook up the motors.

Last month, we mentioned seeing Dr Jefimenko run his electrostatic motors on electricity tapped from the earth's field. We haven't had a chance to try this yet with ours, but it should work. If you want to try, you'll need a needle-pointed piece of music wire a few inches long to start a corona, plus several hundred feet of fine copper wire.

Connect the pointed wire to the fine conductor, get the sharp point up into the air at least 200-300 feet with a kite or balloon, and hook the wire to one side of the motor. Hook the other side of the motor to ground. The earth field antenna should at times be able to develop up to 20,000 volts from the earth's electrical field. If nothing happens, check your equipment, or try another day. The field changes constantly.



The force that makes your hair stand
on end when you comb it on a dry day
drives these fascinating motors

The electrostatic motor on the left turns between three- and four-hundred rpm when connected to the Wimshurst generator at right.

Rotor of the Jefimenko-designed motor shown here is a ½″ plastic disk with a ¼″ shaft cemented carefully in place. Clamp the two outer sheets together before you drill the bearing holes and cut the windows. Aluminum foil electrodes can be cut to approximate shape, glued in place, and trimmed with razor blade. Keep + and − wiring separated by ½″ to avoid arcing. Note that electrodes oppose each other directly; opposing electrodes are of opposite polarity. Cement corner separators to one side for stability, attach other side with screws. To assemble, shim sides apart. Shim thickness of 1/16″ or less is best if rotor can be made to turn freely within this narrow gap. Avoid sharp corners, points, or edges in electrical circuits. They develop corona and leak power into air.

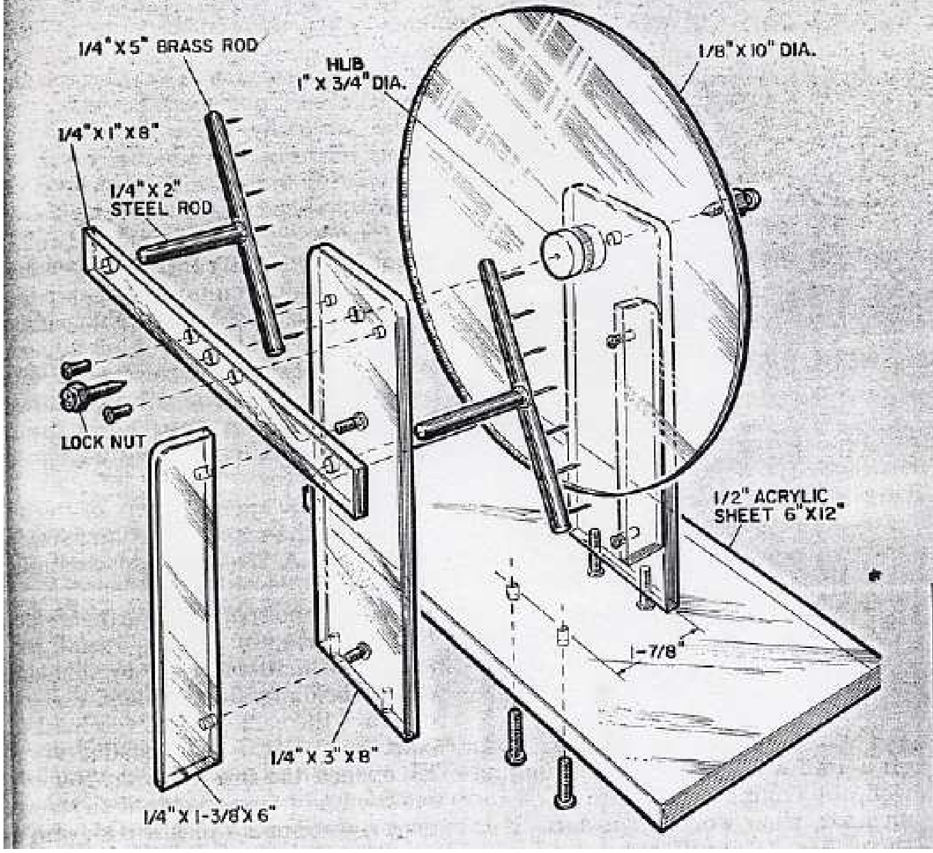
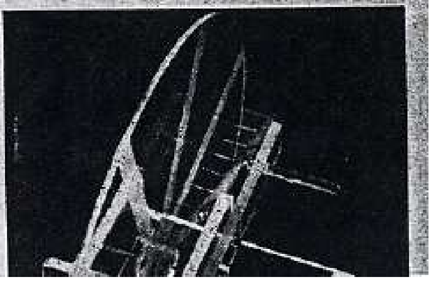
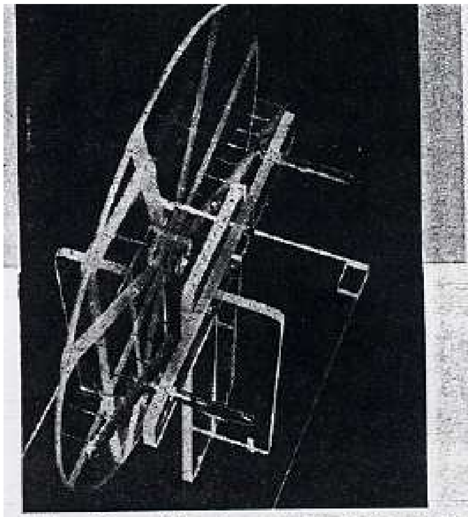
To make Pulleys, drill rotors, cement in ½″ i.d. tubing plus plastic washers (tubing protrudes 1/16″ on inner surface to hold counter-rotating spinning disks ⅛″ apart). Drill ½″ o.d. neutralizer shafts to take ¼″ metal shaft; assemble by slipping rotor-pulley assemblies on neutralizer shafts, neutralizer shafts on metal shaft. Slip assembly into ¼″-deep holes drilled in supports. Make spark globes from polystyrene Christmas balls wrapped in aluminum foil. Brushes must be flexible; use aluminum-braided gift-wrap cord taped to rods. Use any drive that turns disks about 1,200 rpm. Connect pulleys with tape-recorder drive belts.

Best first project: motor designed by physicist J. C. Poggendorff in 1870

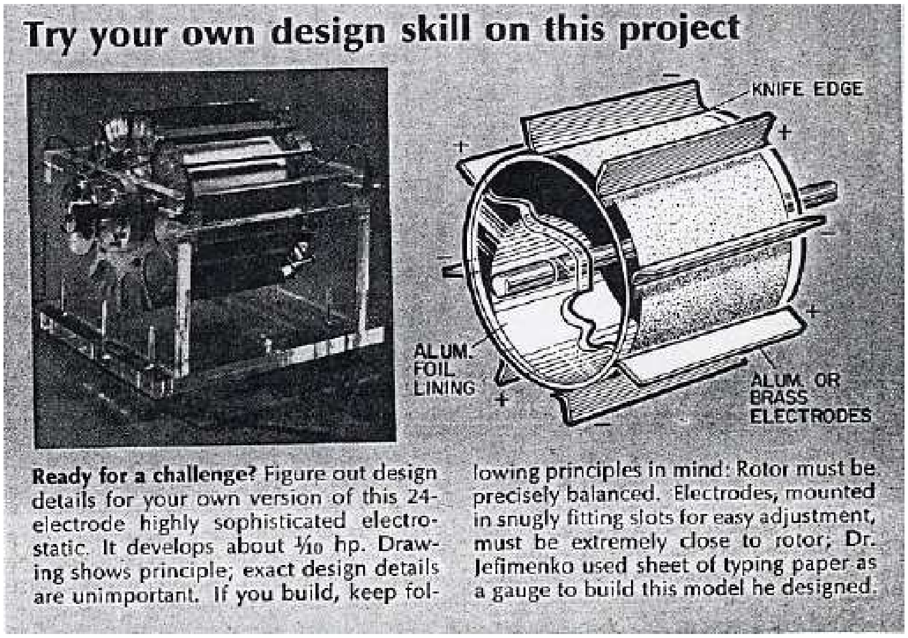


To build Poggendorff motor, drill center of the rotor disk accurately, cement ¾" hub in place, use centerpunch to make bearing indentations in the ends of the hub. Center gap between needle bearings must be adjustable; easiest way is to make bearings from machine screws sharpened on grindstone. Use locknuts to hold fine adjustment. For electrodes, drill seven equidistant holes in brass, steel, or aluminum rods; sharpen brads to a needle point, press-fit them into the holes, grind off heads flush. Brads should protrude about ½". File flat on the back of electrodes, solder or drill, tap, and thread support at right angles. Get extra torque if desired by adding an extra set of electrodes on the opposite side of rotor.





Mounting, with rotor removed, shows the relative positions of supports, needle bearings, and electrodes. Electrode points should be close to disk, but not touching.



Try your own design skill on this project

Ready for a challenge? Figure out design details for your own version of this 24-electrode highly sophisticated electrostatic. It develops about 1/10 hp. Drawing shows principle; exact design details are unimportant. If you build, keep following principles in mind: Rotor must be precisely balanced. Electrodes, mounted in snugly fitting slots for easy adjustment, must be extremely close to rotor; Dr. Jefimenko used sheet of typing paper as a gauge to build this model he designed.

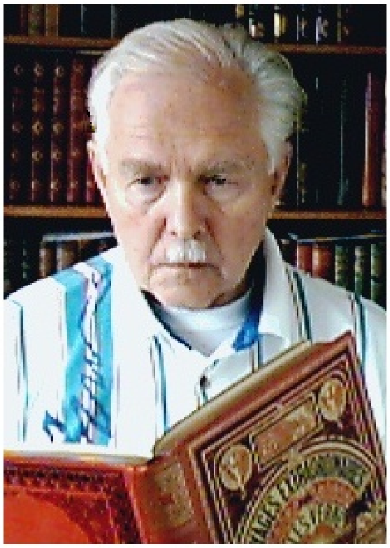
Oleg D. Jefimenko



(October 14, 1922, Kharkiv, Ukraine - May 14, 2009, Morgantown, West Virginia, USA) - physicist and Professor Emeritus at West Virginia University.

Biography

Jefimenko received his B.A. at Lewis and Clark College (1952). He received his M. A. at the University of Oregon (1954). He received his Ph.D. at the University of Oregon (1956). Jefimenko has worked for the development of the theory of electromagnetic retardation and relativity. In 1956, he was awarded the Sigma Xi Prize. In 1971 and 1973, he won awards in the AAPT Apparatus Competition. Jefimenko has constructed and operated electrostatic generators run by atmospheric electricity.

Jefimenko has worked on the generalization of Newton's gravitational theory to time-dependent systems. In his opinion, there is no objective reason for abandoning Newton's force-field gravitational theory (in favor of a metric gravitational theory). He is actively trying to develop and expand Newton's theory, making it compatible with the principle of causality and making it applicable to time-dependent gravitational interactions.

Jefimenko's expansion, or generalization, is based on the existence of the second gravitational force field, the "cogravitational, or Heaviside's, field". This is might also be called a gravimagnetic field. It represents a physical approach profoundly different from the time-space geometry approach of the Einstein general theory of relativity. Oliver Heaviside first predicted this field in the article "A Gravitational and Electromagnetic Analogy" (1893).

http://www.integrityresearchinstitute.org/FutureEnergy/FutureEnergyTech.html

The next energy breakthrough is Dr. Oleg Jefimenko's electrostatic motors. Discovered by Ben Franklin in the 18th century, electrostatic motors are an all-American invention. They are based on the physics of the fair-weather atmosphere that has an abundance of positive electric charges up to an altitude of 20 km. However, the greatest concentration is near the ground and diminishes with altitude rapidly. Dr. Jefimenko discovered that when sharp-pointed antennas are designed for a sufficient length to obtain at least 6000 volts of threshold energy, the fair-weather current density available is about a picoampere per square meter. Such antennas produce about a microampere of current. However, small radioactive source antennas may be used instead that have no threshold voltage and therefore no height requirements. Similar to a nuclear battery design of Dr. Brown, these antennas have larger current potentials depending upon the radioactive source used (alpha or beta source) and ionize the air in the vicinity of the antenna. Electrostatic motors are lighter than electromagnetic motors for the same output power since the motor occupies the entire volume. For example, it is expected that a motor one meter on a side will provide a power of one megawatt and weigh 500 kg or less. Electrostatic motors also require very little metal in their construction and can use mostly plastic for example. They can also operate from a variety of sources and range of voltages. As Dr. Jefimenko points out, "It is clear that electrostatic motor research still constitutes an essentially unexplored area of physics and engineering, and that electrostatic motor research must be considered a potentially highly rewarding area among the many energy-related research endeavors."[5] The atmospheric potential of the planet is not less than 200,000 megawatts. He has succeeded in constructing demonstration motors that run continuously off atmospheric electricity. Jefimenko's largest output motor was an electret design that had a 0.1 Hp rating. [6] Certainly the potential for improvement and power upgrade exists with this free energy machine.

Book Report

So I go out on my step and what to my wondering eyes doth appear but the box from Amazon.com containing the Jefimenko books that Bill Miller shamed me into finally buying. So I take a quick look inside and decide to give an initial report here. (Too much vector math in there for a thorough review.)

These books have some amazing advanced thinking in the understanding of Maxwell and EM. One first thought is the consideration of causality. This is typically totally ignored in the EM community. Evidence of that is the fact that EM waves are widely held to be propagated by the E field creating the H field and the H field creating the E field as it goes along. Too bad it's just not true! Jefimenko points out that causality demands that that an event must be PRECEDED by it's cause! Simultaneous events CANNOT be "causal" of each other. Hence E and H fields of waves are created by the WAVE SOURCE not each other! Same things goes for the E field created by Faraday induction. It simply cannot be "caused" by the time-varying Magnetic Field. "Magnetic induction" is therefore a misnomer. Such induction is caused by the source CURRENT and NOT the magnetic field!

This leads Jefimenko on to note that contrary to the "one E field" theory that has been believed for so many years, the inductive E field is clearly NOT the same field as an electrostatic E field. Jefimenko terms this inductive E field the "Electrokinetic Field" to show that it is a different field from the electrostatic E field. Very good. However, old habits die hard and even Jefimenko persists in writing an expression for a "total E field" following Maxwell as consisting of a sum of the electrostatic and electrokinetic parts as if they were both the "same" kind of E field.

Jefimenko then proceeds to illustrate the electrokinetic fields with a series of calculations and examples using his formulas as an approach. He presents it as basically a "new" way of doing this and in one sense it is compared to the commonly used and non-causal bogus "flux linkage" methods. However, he fails to note that the causal Neumann formula is in essence identical to his formulation and has been a standard formulation for years for the calculation of the "electrokinetic field" or what is usually termed "mutual induction". Nevertheless his example calculations are important basic references to the topic of Faraday induction. And the consideration of causality clearly shows that the Neumann approach has the edge over the "flux linkage" ideas with at times fail to give correct results.

But the subject doesn't end with induction, he pulls gravity into the mix. Of particular interest is that he shows that once you introduce causality into Newton's theory of gravitation, interesting things start to happen! Relativity suddenly begins to show up and even more interesting "action-reaction" is soon discovered to actually be a law that does NOT hold in all cases! The electromagnetic nature of gravity quickly becomes strongly hinted at and without action-reaction laws, those dreamed of devices such as anti-gravity ships and the "force-glove" that you wear to push over a building become theoretical possibilities! These are truly books full of thought-provoking new ways of looking at tired old physics!

I'm not going to be going through the large quantity of field theory math in these books in a hurry, but that's OK because clearly taking the time to go through in detail WILL be worth the effort! What can I say? Listen to Bill Miller and get that order off to Amazon.com now. At roughly $25 each these two books are a huge bargain to the usual EM text books costing hundreds of dollars and then being full of bogus ideas and misunderstandings of the established theories. Just do it! I did and I'm not sorry I did!

http://stupac2.blogspot.com/2007/04/bizarre-and-intriguing-story-of-oleg.html

The Bizarre and Intriguing Story of Oleg Jefimenko and the Solutions to Maxwell's Equations

I recently heard the story of Oleg Jefimenko during a lecture on Electrodynamics, specifically the general solution to Maxwell's Equations.

Jefimenko's tiny bit of fame comes from Jefimenko's Equations, which are the general solution to Maxwell's equations expressed solely in terms of sources, that is charge and current distributions. The equations are messy and difficult to work with, and aren't used much in practice. But they do reveal certain bits of physics (such as the applicability of the quasistatic approximation (the link goes to a thermodynamics page, but the idea is the same) and that fields must be created by sources), and it's always nice to have the general solution to a problem available.

These equations weren't written down until 1966, about a century after Maxwell's Equations were known. Some people will claim (as the Wikipedia article cited does) that Jefimenko's Equations were written down earlier, but those earlier versions are always slightly different and not quite complete. What's really funny is that Jefimenko wrote them down in an attempt to formulate an alternative to Maxwell's equations.

When my current Professor, David Griffiths, was in the process of writing a paper on the subject, he independently derived Jefimenko's equations, and tried to figure out if anyone had done it before. Other than some slightly tricky and annoying math, they're not hard to derive, so someone must have done it. He found that Jefimenko had written them in a book that was published by a company that had only published one other work, also by Jefimenko (apparently regular publishers wouldn't take his books, so he went to a prestige press). He contacted Jefimenko, and Jefimenko didn't believe that he had solved Maxwell's equations, but that he had created an electromagnetic theory separate from (and doubtless better than) Maxwell's. Of course he had done no such thing, his formulation is exactly equivalent to Maxwell's, but he wasn't buying it.

According to Griffiths, Jefimenko currently submits one or two papers a week to American journals, gets denied, then publishes them in Europe (where review is apparently not as stringent). I don't know what they're about, the Wikipedia article says he focuses on overthrowing Einstein's General Relativity and Maxwell.

I found this story behind some esoteric equations to be pretty amusing, and thought others might agree. I hope you've enjoyed the convoluted and intriguing story behind Jefimenko's equations.

[Most of my information comes from a lecture with Griffiths, and as such could not be found online. Anything that is available online has been referenced.]

Electrostatic Motors (Paperback)
by Oleg D. Jefimenko

***Scientific American* (October, 1974)**

Electrostatic Motors Are Powered by Electric Field of the Earth

by

C. L. Stong

Although no one can make a perpetual motion machine, anyone can tap the earth's electric field to run a homemade motor perpetually. The field exists in the atmosphere between the earth's surface and the ionosphere as an electric potential of about 360,000 volts. Estimates of the stored energy range from a million kilowatts to a billion kilowatts.

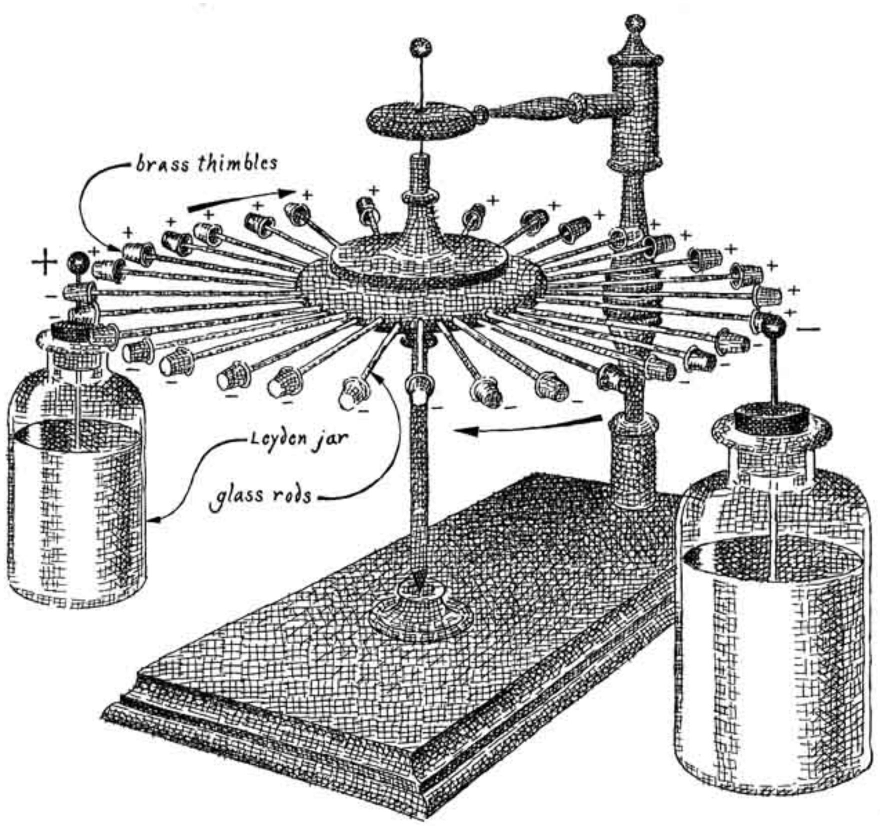
Energy in this form cannot be drawn on directly for driving ordinary electric motors. Such motors develop mechanical force through the interaction of magnetic fields that are generated with high electric current at low voltage, as Michael Faraday demonstrated in 1821. The earth's field provides relatively low direct current at high voltage, which is ideal for operating electrostatic motors similar in principle to the machine invented by Benjamin Franklin in 1748.

Motors of this type are based on the force of mutual attraction between unlike electric charges and the mutual repulsion of like charges. The energy of the field can be tapped with a simple antenna in the form of a vertical wire that carries one sharp point or more at its upper end. During fair weather the antenna will pick up potential at the rate of about 100 volts for each meter of height between the points and the earth's surface up to a few hundred feet. At higher altitudes the rate decreases. During local thunderstorms the pickup can amount to thousands of volts per foot. A meteorological hypothesis is that the field is maintained largely by thunderstorms, which pump electrons out of the air and inject them into the earth through bolts of lightning that continuously strike the surface at an average rate of 200 strokes per second.

Why not tap the field to supplement conventional energy resources? Several limitations must first be overcome. For example, a single sharp point can draw electric current from the surrounding air at a rate of only about a millionth of an ampere. An antenna consisting of a single point at the top of a 60-foot wire could be expected to deliver about a microampere at 2,000 volts; the rate is equivalent to .002 watt. A point-studded balloon tethered by a wire at an altitude of 75 meters might be expected to deliver .075 watt. A serious limitation appears as the altitude of the antenna exceeds about 200 meters. The correspondingly higher voltages become difficult to confine.

At an altitude of 200 meters the antenna should pick up some 20,000 volts. Air conducts reasonably well at that potential. Although nature provides effective magnetic materials in substances such as iron, nickel and cobalt, which explains why the electric-power industry developed around Faraday's magnetic dynamo, no comparably effective insulating substances exist for isolating the high voltages that would be required for electrostatic machines of comparable power. Even so, electrostatic motors, which are far simpler to build than electromagnetic ones, may find applications in special environments such as those from which magnetism must be excluded or in providing low power to apparatus at remote, unmanned stations by tapping the earth's field.

Apart from possible applications electrostatic motors make fascinating playthings. They have been studied extensively in recent years by Oleg D. Jefimenko and his graduate students at West Virginia University. The group has reconstructed models of Franklin's motors and developed advanced electrostatic machines of other types.



Although Franklin left no drawing of his motor, his description of it in a letter to Peter Collinson, a Fellow of the Royal Society, enabled Jefimenko to reconstruct a working model [see illustration at right]. Essentially the machine consists of a rimless wheel that turns in the horizontal plane on low-friction bearings. Each spoke of the "electric wheel," as Franklin called the machine, consists of a glass rod with a brass thimble at its tip. An electrostatic charge for driving the motor was stored in Leyden jars. A Leyden jar is a primitive form of the modern high-voltage capacitor. Franklin charged his jars with an electrostatic generator.

The high-voltage terminals of two or more Leyden jars that carried charges of opposite polarity were positioned to graze the thimbles on opposite sides of the rotating wheel. The motor was started by hand. Thereafter a spark would jump from the high-voltage terminal to each passing thimble and impart to it a charge of the same polarity as that of the terminal. The force of repulsion between the like charges imparted momentum to the wheel.

Conversely, the thimbles were attracted by the oppositely charged electrode of the Leyden jar Franklin placed on the opposite side of the wheel. As the thimbles grazed that jar, a spark would again transfer charge, which was of opposite polarity. Thus the thimbles were simultaneously pushed and pulled by the high-voltage terminals exactly as was needed to accelerate the wheel.

Franklin was not altogether happy with his motor. The reason was that running it required, in his words, "a foreign force, to wit, that of the bottles." He made a second version of the machine without Leyden jars.

In this design the rotor consisted principally of a 17-inch disk of glass mounted to rotate in the horizontal plane on low-friction bearings. Both surfaces of the disk were coated with a film of gold, except for a boundary around the edge. The rotor was thus constructed much like a modern flat-plate capacitor.

Twelve evenly spaced metal spheres, cemented to the edge of the disk, were connected alternately to the top and bottom gold films. Twelve stationary thimbles supported by insulating columns were spaced around the disk to graze the rotating metal spheres. When Franklin placed opposite charges on the top and bottom films and gave the rotor a push, the machine ran just as well as his first design, and for the same reason. According to Franklin, this machine would make up to 50 turns a minute and would run for 30 minutes on a single charge.

Jefimenko gives both motors an initial charge from a 20,000-volt generator. They consume current at the rate of about a millionth of an ampere when they are running at full speed. The rate is equivalent to .02 watt, which is the power required to lift a 20-gram weight 10 centimeters (or an ounce 2.9 inches) in one second.

Jefimenko wondered if Franklin's motor could be made more powerful. As Jefimenko explains, the force can be increased by adding both moving and fixed electrodes. This stratagem is limited by the available space. If the electrodes are spaced too close, sparks tend to jump from electrode to electrode around the rotor, thereby in effect short-circuiting the machine. Alternatively the rotor could be made cylindrical to carry electrodes in the form of long strips or plates. This scheme could perhaps increase the output power by a factor of 1,000.

Reviewing the history of electrostatic machines, Jefimenko came across a paper published in 1870 by Johann Christoff Poggendorff, a German physicist. It described an electrostatic motor fitted with a rotor that carried no electrodes. The machine consisted of an uncoated disk of glass that rotated in the vertical plane on low-friction bearings between opposing crosses of ebonite. Each insulating arm of the crosses supported a comblike row of sharp needle points that grazed the glass.

When opposing combs on opposite sides of the glass were charged in opposite polarity to potentials in excess of 2,000 volts, air in the vicinity of the points on both sides of the glass was ionized. A bluish glow surrounded the points, which emitted a faint hissing sound. The effect, which is variously known as St. Elmo's fire and corona discharge, deposited static charges on both sides of the rotor.

Almost the entire surface of the glass acquired a coating of either positive or negative fixed charges, depending on the polarity of the combs. The forces of repulsion and attraction between glass so charged and the combs were substantially larger than they were in Franklin's charged thimbles. The forces were also steadier, because in effect the distances between the combs and the charged areas remained constant. It should be noted that adjacent combs on the same side of the glass carried charges of opposite polarity, so that the resulting forces of attraction and repulsion acted in unison to impart momentum to the disk, as they did in Franklin's motor.

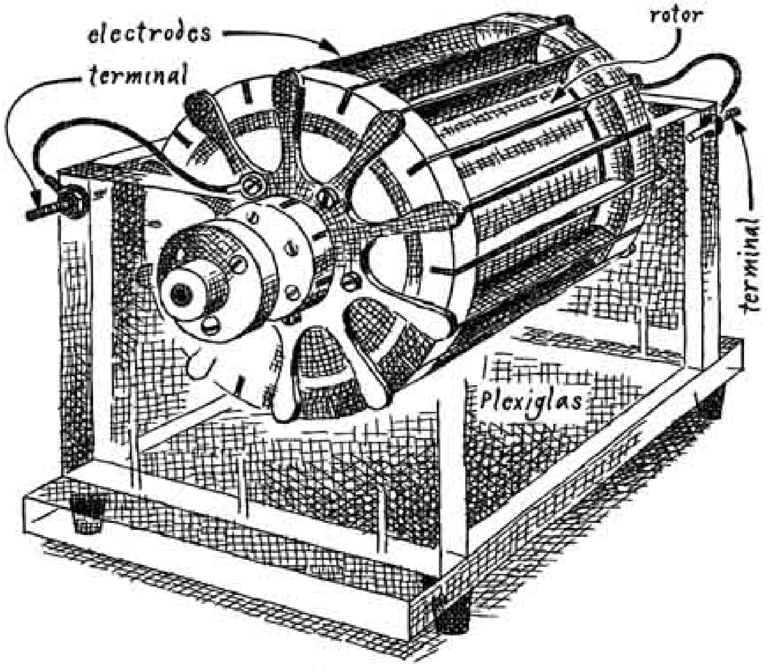
By continued experimentation Poggendorff learned that he should slant the teeth of the combs to spray charge on the glass at an angle. The resulting asymmetrical force made the motor self-starting and unidirectional. When the teeth were perpendicular to the glass surface, the forces were symmetrical, as they were in Franklin's motor. When the machine was started by hand, it ran equally well in either direction.

Poggendorff was immensely pleased by the rate at which his machine converted charge into mechanical motion. He concluded his paper with a faintly odious reference to Franklin's device. "That such a quantity of electricity must produce a far greater force than that in the [Franklin] electric roasting spit," he wrote, "is perfectly obvious and nowadays would not be denied by Franklin himself. With one grain of gunpowder one cannot achieve so much as with one hundred pounds."

Electrostatic motors are now classified in general by the method by which charge is either stored in the machine or transferred to the rotor. Poggendorff's machine belongs to the corona type, which has attracted the most attention in recent years. Although its measured efficiency is better than 50 percent, Poggendorff regarded it merely as an apparatus for investigating electrical phenomena. He wrote that "it would be a sanguine hope if one wanted to believe that any useful mechanical effect could be achieved with it."

Poggendorff's negative attitude toward the usefulness of his design may well have retarded its subsequent development. A modern version of the machine constructed in Jefimenko's laboratory has an output of approximately .1 horsepower. It operates at speeds of up to 12,000 revolutions per minute at an efficiency of substantially more than 50 percent. In one form the modern corona motor consists of a plastic cylinder that turns on an axial shaft inside a concentric set of knife-edge electrodes that spray charge on the surface of the cylinder [see illustration at left]. Forces that act between the sprayed charges and the knife-edge electrodes impart momentum to the cylinder.

Machines of this kind can be made of almost any inexpensive dielectric materials, including plastics, wood and even cardboard. The only essential metal parts are the electrodes and their interconnecting leads. Even they can be contrived of metallic foil backed by any stiff dielectric. The shaft can be made of plastic that turns in air bearings. By resorting to such stratagems experimenters can devise motors that are extremely light in proportion to their power output. Corona motors require no brushes or commutators. A potential of at least 2,000 volts, however, is essential for initiating corona discharge at the knife-edges.



A smaller and simpler version of the machine was demonstrated in 1961 by J. D. N. Van Wyck and G. J. Kühn in South Africa. This motor consisted of a plastic disk about three millimeters thick and 40 millimeters in diameter supported in the horizontal plane by a slender shaft that turned in jeweled bearings. Six radially directed needle points grazed the rim of the disk at equal intervals. When the machine operated from a source of from 8,000 to 13,000 volts, rotational speeds of up to 12,000 revolutions per minute were measured.

I made a corona motor with Plexiglas tubing two inches in diameter and one and a half inches long. It employed stiffbacked single-edge razor blades as electrodes. The bore of the tube was lined with a strip of aluminum foil, a stratagem devised in Jefimenko's laboratory to increase the voltage gradient in the vicinity of the electrodes and thus to increase the amount of charge that can be deposited on the surface of the cylinder. I coated all surfaces of the razor blades except the cutting edges and all interconnecting wiring with "anticorona dope," a cementlike liquid that dries to form a dielectric substance that reduces the loss of energy through corona discharges in nonproductive portions of the circuit.

The axial shaft that supports the cylinder on pivot bearings was cut out of a steel knitting needle. The ends of the shaft were ground and polished to 30degree points. To form the points I chucked the shaft in an electric hand drill, ground the metal against an oilstone and polished the resulting pivots against a wood lap coated with tripoli.

The bearings that supported the pivots were salvaged from the escapement mechanism of a discarded alarm clock. A pair of indented setscrews could be substituted for the clock bearings. The supporting frame was made of quarter-inch Lucite. The motor can be made self-starting and unidirectional by slanting the knife-edges. Those who build the machine may discover, as I did, that the most difficult part of the project, balancing the rotor, is encountered after assembly. The rotor must be balanced both statically and dynamically.

Static balance was achieved by experimentally adding small bits of adhesive tape to the inner surface of the aluminum foil that lines the cylinder until the rotor remained stationary at all positions to which it was set by hand. When the rotor was balanced and power was applied, the motor immediately came up to speed, but it shook violently. I had corrected the imbalance caused by a lump of cement at one end of the rotor by adding a counterweight on the opposite side at the opposite end of the cylinder. Centrifugal forces at the ends were 180 degrees out of phase, thus constituting a couple.

The dynamic balancing, which is achieved largely by cut-and-try methods, took about as much time as the remainder of the construction. To check for dynamic balance suspend the motor freely with a string, run it at low speed and judge by the wiggle where a counterweight must be added. Adhesive tape makes a convenient counterweight material because it can be both applied and shifted easily.

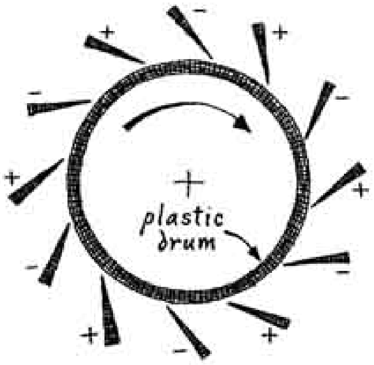
I made the motor as light and frictionless as possible with the objective of operating it with energy from the earth's field. The field was tapped with an antenna consisting of 300 feet of No. 28 gauge stranded wire insulated with plastic. It is the kind of wire normally employed for interconnecting electronic components and is available from dealers in radio supplies.

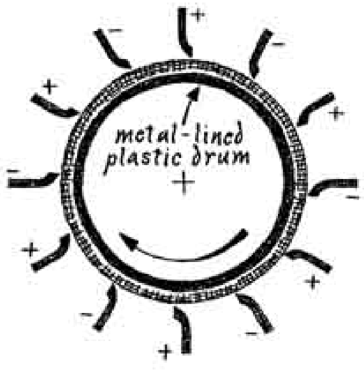
The upper end of the wire was connected to a 20-foot length of metallic tinsel of the kind that serves for decorating a Christmas tree. The tinsel functioned as multiple needle points. Strips cut from window screening would doubtless work equally well.

The upper end of the tinsel was hoisted aloft by a cluster of three weather balloons. Such balloons, each three feet in diameter, and the helium to inflate them are available from the Edmund Scientific Co. (300 Edscorp Building, Barrington, N.J. 08007). The weight in pounds that a helium-filled balloon of spherical shape can lift is roughly equal to a quarter of the cube of its radius in feet. To my delight the motor began to run slowly when the tinsel reached an altitude of about 100 feet. At 300 feet the rotor made between 500 and 700 revolutions per minute.

A note of warning is appropriate at this point. Although a 300-foot vertical antenna can be handled safely in fair weather, it can pick up a lethal charge during thunderstorms. Franklin was incredibly lucky to have survived his celebrated kite experiment. A European investigator who tried to duplicate Franklin's observations was killed by a bolt of lightning. The 300-foot antenna wire can hold enough charge to give a substantial jolt, even during fair weather. Always ground the lower end of the wire when it is not supplying a load, such as the motor.

To run the motor connect the antenna to one set of electrodes and ground the other set. Do not connect the antenna to an insulated object of substantial size, such as an automobile. A hazardous charge can accumulate. Never fly the balloon in a city or in any other location where the antenna can drift into contact with a high-voltage power line. Never fly it below clouds or leave it aloft unattended.





A variety of corona motors have been constructed in Jefimenko's laboratory. He has learned that their performance can be vastly improved by properly shaping the corona-producing electrodes [see illustration at right]. The working surface of the rotors should be made of a fairly thin plastic, such as Plexiglas or Mylar. Moreover, as I have mentioned, the inner surface of the cylinder should be backed by conducting foil to enhance the corona. Effective cylinders can be formed inexpensively out of plastic sewer pipe. Corona rotors can of course also be made in the form of disks.

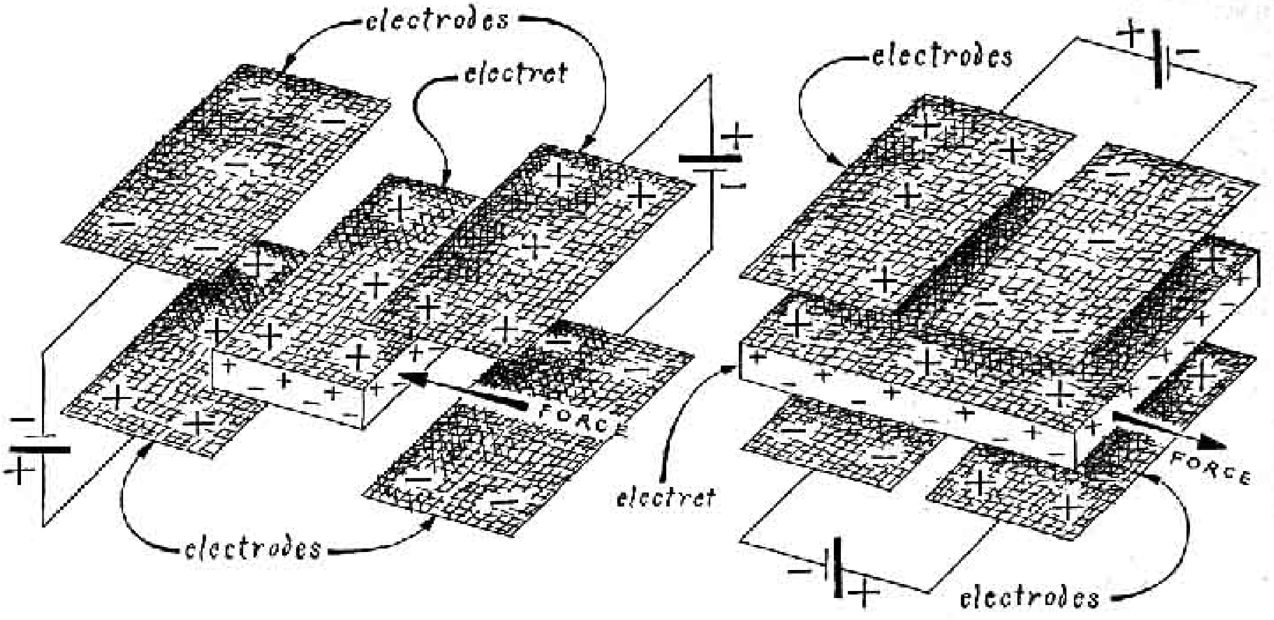
One model consists of a series of disks mounted on a common shaft. Double-edged electrodes placed radially between adjacent disks function much like Poggendorff's combs. This design needs no foil lining or backing because a potential gradient exists between electrodes on opposite sides of the disks. It is even possible to build a linear corona motor, a design that serves to achieve translational motion. A strip of plastic is placed between sets of knife-edge electrodes slanted to initiate motion in the desired direction.

Notwithstanding the problem of handling potentials on the order of a million volts without effective insulation materials, Jefimenko foresees the possibility of at least limited application of corona power machines. In The Physics Teacher (March, 1971) he and David K. Walker wrote: "These motors could be very useful for direct operation from high-voltage d.c. transmission lines as, for example, the 800 kV Pacific Northwest-Southwest Intertie, which is now being constructed between the Columbia River basin and California. It is conceivable that such motors could replace the complex installations now needed for converting the high-voltage d.c. to low-voltage a.c. All that would be required if corona motors were used for this purpose would be to operate local low-voltage a.c. generators from corona motors powered directly from the high-voltage d.c. line."

As Jefimenko points out, a limiting factor of the corona motor is its required minimum potential of 2,000 volts. This limitation is circumvented by a novel electrostatic motor invented in 1961 by a Russian physicist, A. N. Gubkin. The motor is based on an electret made in 1922 by Mototaro Eguchi, professor of physics at the Higher Naval College in Tokyo.

An electret is a sheet or slab of waxy dielectric material that supports an electric field, much as a permanent magnet carries a magnetic field. Strongly charged carnauba-wax electrets are available commercially, along with other electrostatic devices, from the Electret Scientific Company (P.O. Box4132, Star City, W.Va. 26505). A recipe for an effective electret material is 45 percent carnauba wax, 45 percent water-white rosin and 10 percent white beeswax. Some experimenters substitute Halowax for the rosin.

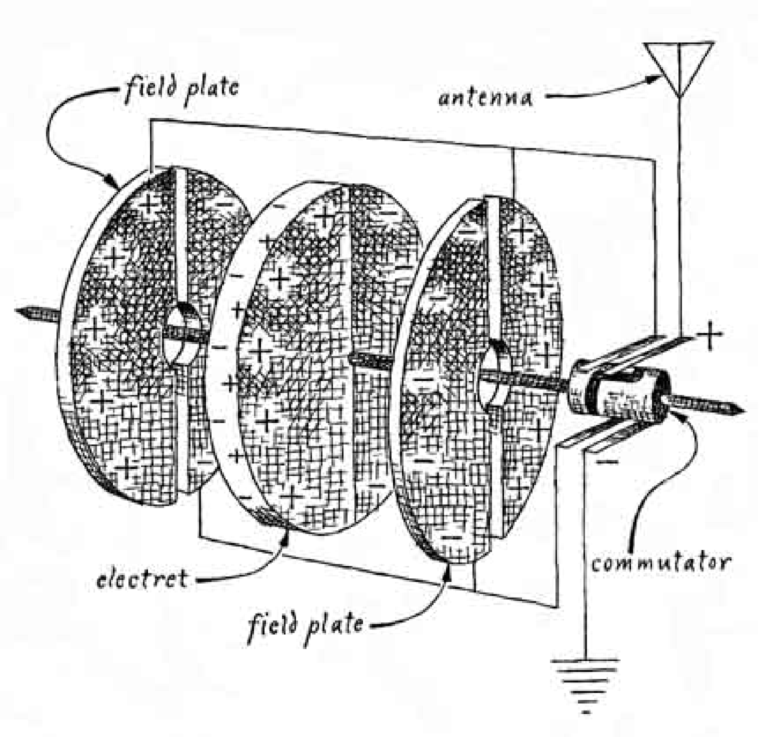
The ingredients are melted and left to cool to the solid phase in a direct-current electric field of several thousand volts. The wax continues to support the field even though the external source of potential is turned off [see "The Amateur Scientist, SCIENTIFIC AMERICAN, November, 1960, and July, 1968]. The electret reacts to neighboring charges exactly as though it were a charged electrode, that is, it is physically attracted or repelled depending on the polarity of the neighboring electrode.



Gubkin harnessed this effect to make a motor. The rotor consisted of a pair of electrets in the shape of sectors supported at opposite ends of a shaft. The center of the shaft was supported transversely by an axle. When the rotor turned, the electrets were swept between adjacent pairs of charged metallic plates, which were also in the form of sectors.

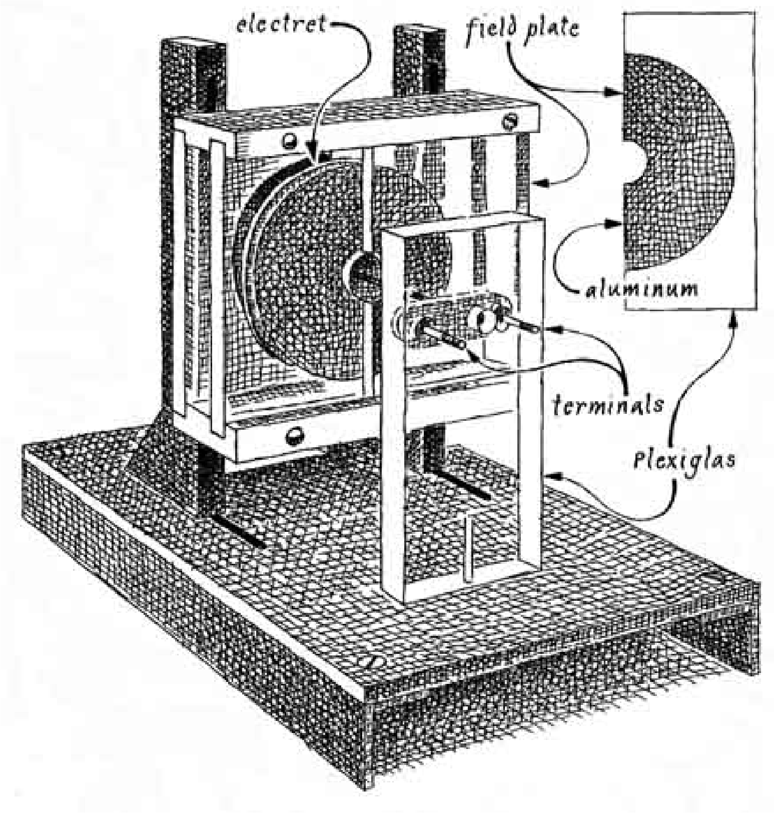
The plates were electrified by an external source of power through the polarity-reversing switch known as a commutator. The commutator applied to the electrodes a charge of polarity opposite to the charge of the attracted electret. As the electret moved between the attracting plates, however, the commutator switched the plates to matching polarity. The alternate push and pull imparted momentum to the rotor in exact analogy to Franklin's motor.

Gubkin's motor was deficient in two major respects. The distances between the electrodes and the electrets were needlessly large, so that the forces of attraction and repulsion were needlessly weak. Moreover, during the electret's transit between electrodes its surfaces were unshielded. Unshielded electrets attract neutralizing ions from the air and lose their charge within hours or days.



Both inherent deficiencies of Gubkin's motor have been corrected in Jefimenko's laboratory by taking advantage of what is termed the slot effect. Instead of sandwiching the electret alternately between pairs of metal plates, Jefimenko employs opposing pairs of adjacent plates [see illustration at rightt]. The adjacent plates are separated by a narrow slot. When adjacent plates carry charges of opposite polarity, the electret experiences a force at right angles to the slot and in the plane of the electret. The strength of the force is at a maximum because the electret is close to the electrodes. Simultaneously the electrodes function as shields to prevent the neutralization of the electret by free ions.

Motors based on the slot effect can be designed in a number of forms. One design consists of an electret in the shape of a wafer-thin sheet of Mylar supported by a flat disk of balsa wood 100 millimeters in diameter and three millimeters thick. (A long-lasting charge is imparted to the Mylar by immersing it in a field of a few thousand volts from an electrostatic generator after the motor is assembled.) This rotor is sandwiched between four semicircular sectors that are cross-connected [see illustration].



The electret is mounted on a four-millimeter shaft of plastic that turns in jeweled bearings. The conducting surfaces of the commutator consist of dried India ink. The brushes are one-millimeter strips of kitchen aluminum foil. The motor operates on a few microwatts of power.

Jefimenko has demonstrated a similar motor that was designed to turn at a rate of about 60 revolutions per minute and develop a millionth of a horsepower on a 24-foot antenna having a small polonium probe at its upper end. (By emitting positive charges probes of this type tap the earth's field somewhat more efficiently than needle points do.) The performance of the motor easily met the design specifications. The charm of these motors lies in the fact that, although they do not accomplish very much, they can run forever.

(57) **ABSTRACT**

Atmospheric Transduction System including a Power Frequency broadcast station, a receiver, and a network. The Power Frequency broadcast station includes a transmitter and a computer server. The receiver is in communication with the Power Frequency broadcast transmitter and also includes a user interface for receiving user input commands comprising a request for information from the Power Frequency broadcast station. The receiver is configured to establish a two-way communication path between the receiver and the Power Frequency broadcast transmitter. The network is in communication with the transducer, controller and the receiver for exchanging information therebetween. In response to oscillation translation and/or rotation of the electronic transducer, portions of forces induced by the mass are transferred to the piezoelectric elements. Electrical energy output by these piezoelectric elements is received in a power controller and can be applied to the battery as self charging. The piezoelectric transducer includes a conductive rotor and bearings, at least one of them incorporating a vibrator of mechanical oscillation, having a piezoelectric transducer converting mechanical vibrations into electric power.

[0001] NONE

BACKGROUND OF THE INVENTION

Field of the Invention

[0002] Self-propelled travel is a type of recreational adventure travel using human powered transport. This includes non-motorized machines such as a bicycle or skateboard. It is in contrast to traveling in a powered vehicle (such as an automobile) as in that case it is the vehicle which powers itself. Self-propelled travel is used to travel short distances or even for much longer distances such as bicycle touring. Self propelled describes something that moves, progresses or acts on its own power without needing outside help. Leonardo da Vinci's 1478 Self-Propelled Car: It was more than 500 years ago, however—sometime around the year 1478 to be more or less specific—when Leonardo drew out his plans for the world's first self-propelled vehicle. Experts originally believed two leaf springs, the simplest form of the spring typically used for automotive suspensions, somehow powered the vehicle. Closer inspection eventually revealed the power came from bigger, coiled springs located in tambours, cylindrical drum-like casings, inside the car's frame. The machine works like a robot or a wind-up toy simply by rotating the wheels opposite of their intended direction, which winds up the springs inside and gives it power. Self propulsion (of a vehicle) provided with its own source of tractive power rather than requiring an external means of propulsion.

[0003] In the middle of the 18th century, Benjamin Franklin's experiments showed that electrical phenomena of the atmosphere were not fundamentally different from those produced in the laboratory. By 1749, Franklin observed lightning to possess almost all the properties observable in electrical machines.

[0004] In July 1750, Franklin hypothesized that electricity could be taken from clouds via a tall metal aerial with a sharp point. Before Franklin could carry out his experiment, in 1752 Thomas-Francois Dalibard erected a 40-foot (12 m) iron rod at Marly-la-Ville, near Paris, drawing sparks from a passing cloud. With ground-insulated aerials, an experimenter could bring a grounded lead with an insulated wax handle close to the aerial, and observe a spark discharge from the aerial to the grounding wire. In May 1752, Dalibard affirmed that Franklin's theory was correct.

Piezoelectric Motor

[0005] A piezoelectric motor or piezo motor is a type of electric motor based upon the change in shape of a piezoelectric material when an electric field is applied. Piezoelectric motors make use of the converse piezoelectric effect whereby the material produces acoustic or ultrasonic vibrations in order to produce a linear or rotary motion. In one mechanism, the elongation in a single plane is used to make a series stretches and position holds, similar to the way a caterpillar moves. A transducer is a device that converts one form of energy to another. Energy types include (but are not limited to) electrical, mechanical, electromagnetic (including light), chemical, acoustic or thermal energy. While the term transducer commonly implies the use of a sensor/detector, any device which converts energy can be considered a transducer. Transducers are widely used in measuring instruments. Piezoelectric materials can also be used to harvest low levels of mechanical energy into electrical energy suitable for powering wireless sensors, low power microprocessors or charging batteries. Rotary Uses include rotating machines such as fans, turbines, drills, the wheels on electric cars, locomotives and conveyor belts. Also, in many vibrating or oscillating machines, an electric motor spins an unbalanced mass, causing the motor (and its mounting structure) to vibrate.

Atmospheric Electricity

[0006] There is always free electricity in the air and in the clouds, which acts by induction on the earth and electromagnetic devices. Experiments have shown that there is always free electricity in the atmosphere, which is sometimes negative and sometimes positive, but most generally positive, and the intensity of this free electricity is greater in the middle of the day than at morning or night and is greater in winter than in summer. In fine weather, the potential increases with altitude at about 30 volts per foot (100 V/m).

Atmospheric Layers

[0007] The electrical conductivity of the atmosphere increases exponentially with altitude. The amplitudes of the electric and magnetic components depend on season, latitude, and height above the sea level. The greater the altitude the more atmospheric electricity abounds. The exosphere is the uppermost layer of the atmosphere and is estimated to be 500 km to 1000 km above the Earth's surface, and its upper boundary at about 10,000 km. The thermosphere (upper atmosphere) is the layer of the Earth's atmosphere directly above the mesosphere and directly below the exosphere. Within this layer, ultraviolet radiation causes ionization. Theories that have been proposed to explain the phenomenon of the polar aurora, but it has been demonstrated by experiments that it is due to currents of positive electricity passing from the higher regions of the atmosphere to the earth.

[0008] The mesosphere (middle atmosphere) is the layer of the Earth's atmosphere that is directly above the stratosphere and directly below the thermosphere. The mesosphere is located about 50-80/85 km above Earth's surface. The stratosphere (middle atmosphere) is a layer of Earth's atmosphere that is stratified in temperature and is situated between about 10 km and 50 km altitude above the surface at moderate latitudes, while at the poles it starts at about 8 km altitude. The stratosphere sits directly above the troposphere and directly below the mesosphere. The troposphere (lower atmosphere) is the densest layer of the atmosphere.

[0009] The planetary boundary layer (PBL), also known as the atmospheric boundary layer (ABL), is the lowest part of the atmosphere and its behavior is directly influenced by its contact with the planetary surface. It is also known as the "exchange layer". (see also: p-n junction.)

[0010] There is a potential gradient at ground level ("Atmosphere ground layer") and this vertical field corresponds to the negative charge in and near the Earth's surface. The negative potential gradient falls rapidly as altitude increases from the ground. Most of this potential gradient is in the first few kilometers. The positive potential gradient rises rapidly as altitude increases from the ground. Volta, over two centuries before the 21st century, discovered with some degree of exactitude that the proportions of the ordinates of the curve or gradient of electric potential increased as the distance from the earth increases, and, more recently, Engel has provided data to calculate the increase (Image to the right).

Drum-Type Generator

[0011] A drum-type homopolar generator has a magnetic field (B) that radiates radially from the center of the drum and induces voltage (V) down the length of the drum. A conducting drum spun from above in the field of a "loudspeaker" type of magnet that has one pole in the center of the drum and the other pole surrounding the drum could use conducting ball bearings at the top and bottom of the drum to pick up the generated current.

Astrophysical Unipolar Inductors

[0012] Unipolar inductors occur in astrophysics where a conductor rotates through a magnetic field, for example, the movement of the highly conductive plasma in a cosmic body's ionosphere through its magnetic field. In their book, Cosmical Electrodynamics, Hannes Alfvén and Carl-Gunne Fälthammar write:

[0013] "Since cosmical clouds of ionized gas are generally magnetized, their motion produces induced electric fields [. . .] For example the motion of the magnetized interplanetary plasma produces electric fields that are essential for the production of aurora and magnetic storms" [. . .]

[0014] " . . . the rotation of a conductor in a magnetic field produces an electric field in the system at rest.

[0015] This phenomenon is well known from laboratory experiments and is usually called 'homopolar' or 'unipolar' induction.

The Faraday Disc

[0016] The homopolar generator was developed first by Michael Faraday during his experiments in 1831. It is frequently called the Faraday disc in his honor. It was the beginning of modern dynamos—that is, electrical generators which operate using a magnetic field. It was very inefficient and was not used as a practical power source, but it showed the possibility of generating electric power using magnetism, and led the way for commutated direct current dynamos and then alternating current alternators.

Boeing 737-800

[0017] The Boeing Fuel Cell Demonstrator Airplane has a Proton Exchange Membrane (PEM) fuel cell/lithium-ion battery hybrid system to power an electric motor, which is coupled to a conventional propeller. The fuel cell provides all power for the cruise phase of flight. During takeoff and climb, the flight segment that requires the most power, the system draws on lightweight lithium-ion batteries.

[0018] The demonstrator aircraft is a Dimona motor glider, built by Diamond Aircraft Industries of Austria, which also carried out structural modifications to the aircraft. With a wing span of 16.3 meters (53.5 feet), the airplane will be able to cruise at approximately 100 kilometers per hour (62 miles per hour) on power from the fuel cell.

[0019] Nikola Tesla explored the wireless transmission of energy through his work with radio and microwaves and his creation of the Tesla coil and the magnifying transmitter. In 1898, Tesla demonstrated his radio-controlled boat, which he was able to control remotely. In the 1930s, Tesla claimed to have invented a particle beam weapon, or, as some called it, a "peace ray." The device was, in theory, capable of generating an intense, targeted beam of energy and sending it across great distances to demolish warplanes, foreign armies, or anything else you'd rather didn't exist.

[0020] "Roy J. Meyers, British Patent Number 1098"

[0021] This invention relates to improvements in apparatus for the production of electrical currents, and the primary object in view is the production of a commercially serviceable electrical current without the employment of mechanical or chemical action. To this end the invention comprises means for producing what I believe to be dynamic electricity from the earth and its ambient elements.

[0022] Edward Leedskalnin: Magnetic Current—

[0023] The Perpetual Motion Holder is primarily a teaching device but it has many functions including an electromagnet, this is easy enough to see; it is a generator—spin a magnet between the coils it will generate electricity; it functions as a transformer; it demonstrates how permanent magnets are made, and is a holder of perpetual motion.

Strategic Defense Initiative

[0024] The Strategic Defense Initiative (SDI) was proposed to use ground and space-based systems to protect the United States from attack by strategic nuclear ballistic missiles.

Description of the Related Art

[0025] The present invention relates to a ball bearing assembly structure, an electromagnetic clutch having the ball bearing assembly structure, and a gas compressor equipped with the electromagnetic clutch.

[0026] When operating the gas compressor, the electromagnet of the electromagnetic clutch is energized to attract or adsorb the follower armature plate to an end surface of the prime-mover pulley and join the prime-mover pulley and the rotor shaft, thereby rotating the rotor shaft.

[0027] The ball bearing of the electromagnetic clutch conventionally has used one having an even number of balls per row. Generally, the ball bearing causes vibration and noise due to rotation. In the case of the ball bearing rotating while undergoing a radial load due to a tension of the belt, vibration and noise considerably occur. Particularly when other vibration and noise levels are lowered during engine idling, the vibration and noise of the ball bearing transmitted to the vehicular compartment is not negligible.

[0028] The inventor has conducted various experiments and discovered that the one factor of high vibration and noise level is an even number of balls of the ball bearing. In the ball bearing having an even number of balls per one row, the balls are in a facing relation to have linear-symmetry arrangement between the inner race and the outer race. The deformation and vibration at a regular particular frequency is caused in the inner and outer races. It is to be considered that the vibration as a source also increases noise.

[0029] The present invention relates generally and in various embodiments to piezoelectric mechanical systems. More specifically, the present invention relates generally and in various embodiments to atmospheric oscillation transducer apparatuses, systems, and methods.

[0030] Although various implementations of the present invention, among many, may be described herein with reference to the specific illustrative embodiments related to particular applications, those skilled in the art will understand that the invention is not in any way intended to be limited to such embodiments and/or applications. Those having ordinary skill in the art and reference to the description of the embodiments herein will recognize additional modifications, applications, and other embodiments falling within the scope of the claimed invention and additional fields in which the present invention may be practiced.

[0031] Digital Radio (also known as Satellite Radio or Satellite Digital Audio Radio Service (SDARS)) is a subscriber-based digital radio service that is broadcast via satellites. Digital radio service provides compact-disc (CD) quality programming that may be digitally transmitted via one or more satellites and/or space stations to one or more Earth-based (terrestrial) digital radio stations, receivers, and/or repeaters. In satellite-based direct-broadcast radio services, digitally-encoded audio program material may be broadcast to terrestrial fixed or mobile digital radio receivers. Fixed receivers may include, for example, stand alone digital radio receivers or digital radio receivers connected via computer networks, including for example, the Internet. Mobile receivers may include, for example, digital radio receivers located in automobiles, aircrafts, watercrafts, and the like.

[0032] Satellite-based digital audio radio services such as SDARS, for example, may be broadcast to one or more digital radio receivers either directly from an orbiting satellite, or indirectly from one or more repeater stations. Such repeater stations may be useful where the digital radio receiver is located in a shielded location or where there is no direct line of sight between the radio and the satellite. In other digital audio radio services systems, the audio programs also may be transmitted in digital form by one or more space stations directly to fixed, mobile, and/or portable radio stations. Such systems may comprise, for example, orbiting satellites, complementary repeating terrestrial transmitters, telemetry, tracking, and control facilities.

[0033] Combinations of mechanical devices U.S. Pat. Nos. 4,019,073, 6,615,968 and atmospheric system interaction are disclosed in U.S. Pat. Nos. 1,119,732, 787,412, 6,902,513 to Nikola Tesla; 28,793 to Charles Vion; and U.S. Pat. No. 1,540,998 to Herman Plauson. Lastly, U.S. Pat. No. 8,102,078 and US2008/0009240. Agnoff discloses an Oscillating watch winder in U.S. Pat. No. 6,543,929, Jennings further discloses an oscillating smart device in application No. 13,572,679.

[0034] As illustrated by a large body of prior art, including the above-noted patents, and a large number of commercial devices, efforts are continuously being made in an attempt to improve helmets, headsets and their methods of fabrication. Nothing in the prior art, however, suggests the present inventive combination of materials and method steps as herein described and claimed. The present invention achieves its purposes, objects and advantages over the prior art through a new, useful and unobvious combination of components and method steps which improve safety, comfort and noise abatement performance.

[0035] Therefore, it is an object of this invention to provide Effectively, the provision of energy such that it meets the needs of the present without compromising the ability of future generations to meet their own needs . . . . Sustainable Energy has two key components: renewable energy and energy efficiency.

[0036] It is still a further objection of this invention to promote Dynamic harmony between equitable availability of energy-intensive goods and services to all people and the preservation of the earth for future generations." And, "the solution will lie in finding sustainable energy sources and more efficient means of converting and utilizing energy.

[0037] It is a further object of the present invention to produce Green Power Energy: is energy that can be extracted, generated, and/or consumed without any significant negative impact to the environment, green power; as electricity produced from solar, wind, geothermal, biogas, biomass, and low-impact small hydroelectric sources.

[0038] Thus, there is a need for a clean energy system that uses atmospheric electricity.

Prior Art

[0039] Quartz crystals have been in regular use for many years to give an accurate frequency for all radio transmitters, radio receivers and computers. Their accuracy comes from an amazing set of coincidences: Quartz—which is silicon dioxide like most sand—is unaffected by most solvents and remains crystalline to hundreds of degrees Fahrenheit. The property that makes it an electronic miracle is the fact that, when compressed or bent, it generates a charge or voltage on its surface. This is a fairly common phenomenon called the Piezoelectric effect. In the same way, if a voltage is applied, quartz will bend or change its shape very slightly.

[0040] If a bell were shaped by grinding a single crystal of quartz, it would ring for minutes after being tapped. Almost no energy is lost in the material. A quartz bell—if shaped in the right direction to the crystalline axis—will have an oscillating voltage on its surface, and the rate of oscillation is unaffected by temperature. If the surface voltage on the crystal is picked off with plated electrodes and amplified by a transistor or integrated circuit, it can be re-applied to the bell to keep it ringing.

[0041] The electronics of the watch initially amplifies noise at the crystal frequency. This builds or regenerates into oscillation—it starts the crystal ringing. The output of the watch crystal oscillator is then converted to pulses suitable for the digital circuits.

Polymers

[0042] Polyvinylidene fluoride (PVDF): PVDF exhibits piezoelectricity several times greater than quartz. Unlike ceramics, where the crystal structure of the material creates the piezoelectric effect, in polymers the intertwined long-chain molecules attract and repel each other when an electric field is applied.

Near Space

[0043] Solar particles become trapped within the Earth's magnetic field and form radiation belts. The Van Allen radiation belt is a torus of energetic charged particles (i.e. a plasma) around Earth, trapped by Earth's magnetic field.

[0044] At elevations above the clouds, atmospheric electricity forms a continuous and distinct element (called the electrosphere) in which the Earth is surrounded. The electrosphere layer (from tens of kilometers above the surface of the earth to the ionosphere) has a high electrical conductivity and is essentially at a constant electric potential. The ionosphere is the inner edge of the magnetosphere and is the part of the atmosphere that is ionized by solar radiation. (Photoionisation is a physical process in which a photon is incident on an atom, ion or molecule, resulting in the ejection of one or more electrons.)

Advantages/Disadvantages

[0045] Energy in electronic elements: Electric potential energy, or electrostatic potential energy, is a potential energy (measured in joules) that results from conservative Coulomb forces and is associated with the configuration of a particular set of point charges within a defined system. The term "electric potential energy" is used to describe the potential energy in systems with time-variant electric fields, while the term "electrostatic potential energy" is used to describe the potential energy in systems with time-invariant electric fields.

[0046] Capacitance is the ability of a body to store an electrical charge. Any body or structure that is capable of being charged, either with static electricity or by an electric current, exhibits capacitance. A common form of energy storage device is a parallel-plate capacitor. In a parallel plate capacitor, capacitance is directly proportional to the surface area of the conductor plates and inversely proportional to the separation distance between the plates. If the charges on the plates are +q and −q, and V gives the voltage between the plates, then the capacitance C is given by

$$C=q/V.$$

[0047] The capacitance is a function only of the physical dimensions (geometry) of the conductors and the permittivity of the dielectric. It is independent of the potential difference between the conductors and the total charge on them.

[0048] Piezoelectricity is the combined effect of the electrical behavior of the material:

$$D=\in E$$

where D is the electric charge density displacement (electric displacement), $\in$ is permittivity and E is electric field strength, and

Hooke's Law: $S=sT$

where S is strain, s is compliance and T is stress.

[0049] Polyvinylidene fluoride, or polyvinylidene difluoride (PVDF) is a highly non-reactive and pure thermoplastic fluoropolymer produced by the polymerization of vinylidene difluoride. PVDF is a specialty plastic material in the fluoropolymer family; it is used generally in applications requiring the highest purity, strength, and resistance to solvents, acids, bases and heat and low smoke generation during a fire event. Compared to other fluoropolymers, it has an easier melt process because of its relatively low melting point of around 177° C.

[0050] It has a low density (1.78) and low cost compared to the other fluoropolymers. It is available as piping products, sheet, tubing, films, plate and an insulator for premium wire. It can be injected, molded or welded and is commonly used in the chemical, semiconductor, medical and defense industries, as well as in lithium ion batteries. It is also available as a crosslinked closed cell foam, used increasingly in aviation and aerospace. PVDF has a glass transition temperature (Tg) of about −35° C. and is typically 50-60% crystalline. To give the material its piezoelectric properties, it is mechanically stretched to orient the molecular chains and then poled under tension. PVDF exists in several forms: alpha (TGTG'), beta (TTTT), and gamma (TTTGTTTG') phases, depending on the chain conformations as trans (T) or gauche (G) linkages. When poled, PVDF is a ferroelectric polymer, exhibiting efficient piezoelectric and pyroelectric properties. These characteristics make it useful in sensor and battery applications. Thin films of PVDF are used in some newer thermal camera sensors.

[0051] Copolymers: Copolymers of PVDF are also used in piezoelectric and electrostrictive applications. One of the most commonly-used copolymers is P(VDF-trifluoroethylene), usually available in ratios of about 50:50 wt % and 65:35 wt % (equivalent to about 56:44 mol % and 70:30 mol %). Another one is P(VDF-tetrafluoroethylene). They improve the piezoelectric response by improving the crystallinity of the material.

[0052] While the copolymers' unit structures are less polar than that of pure PVDF, the copolymers typically have a much higher crystallinity. This results in a larger piezoelectric response: d33 values for P(VDF-TrFE) have been recorded to be as high as −38 pC/N versus −33 pC/N in pure PVDF.

[0053] Applications:

[0054] The piezoelectric properties of PVDF are used to advantage to manufacture tactile sensor arrays, inexpensive strain gauges and lightweight audio transducers. Piezoelectric panels made of PVDF are used on the Venetia Burney Student Dust Counter, a scientific instrument of the New Horizons space probe that measures dust density in the outer solar system. PVDF is the standard binder material used in the production of composite electrodes for lithium ion batteries. 1-2% weight solution of PVDF dissolved in N-Methyl-2-pyrrolidone (NMP) is mixed with an active lithium storage material such as graphite, silicon, tin, $LiCoO_2$, $LiMn_2O_4$, or $LiFePO_4$ and a conductive additive such as carbon black or carbon nanofibers. This slurry is cast onto a metallic current collector and the NMP is evaporated to form a composite or paste electrode. PVDF is used because it is chemically inert over the potential range used and does not react with the electrolyte or lithium. Piezoelectric elements can be used in laser mirror alignment, where their ability to move a large mass (the mirror mount) over microscopic distances is exploited to electronically align some laser mirrors. By precisely controlling the distance between mirrors, the laser electronics can accurately maintain optical conditions inside the laser cavity to optimize the beam output. Piezoelectric sensors especially are used with high frequency sound in ultrasonic transducers for medical imaging and also industrial nondestructive testing (NDT).

[0055] For many sensing techniques, the sensor can act as both a sensor and an actuator—often the term transducer is preferred when the device acts in this dual capacity, but most piezo devices have this property of reversibility whether it is used or not. Ultrasonic transducers, for example, can inject ultrasound waves into the body, receive the returned wave, and convert it to an electrical signal (a voltage). Most medical ultrasound transducers are piezoelectric.

[0056] Advantageously,

[0057] Sustainable energy is the sustainable provision of energy that meets the needs of the present without compromising the ability of future generations to meet their needs. Technologies that promote sustainable energy include renewable energy sources, such as hydroelectricity, solar energy, wind energy, wave power, geothermal energy, and tidal power, and also technologies designed to improve energy efficiency.

[0058] This sequence of oscillations causes the rotor within the watch to spin rapidly thereby winding the watch in a manner closely simulating the spinning of the rotor that occurs during normal winding of the watch when the watch is worn by a user. Due to the forces that are exerted, the rotor spins around the watch shaft during the oscillations, as opposed to the partial rotation observed in prior art mechanisms. Therefore, the time required to wind the watch, and the energy required, is substantially reduced. Moreover, since the rotor is spinning about the shaft, as opposed to merely being held in a downward position while the watch is rotated, winding more closely approximating the design mechanism is achieved, thereby putting less wear on the watch.

[0059] This invention relates to satellite communications systems using multiple spot beams from a geosynchronous earth orbit satellite to provide selective coverage of the continental United States and, more particularly, relates to a system having a satellite receiving hub in every spot beam that allows for asynchronous communications between each hub and the satellite for maximizing frequency re-use.

[0060] These purposes, objects and advantages should be construed as merely illustrative of some of the more prominent features and applications of the present invention. Many other beneficial results can be obtained by applying the disclosed invention in a different manner or by modifying the invention within the scope of the disclosure. Accordingly, other purposes, objects and advantages as well as a fuller understanding of the invention may be had by referring to the summary herein mentioned and detailed description describing the preferred embodiments of the invention, in addition to the scope of the invention, as defined by the claims, taken in conjunction with the accompanying drawings.

SUMMARY OF THE INVENTION

[0061] In one general respect, an embodiment of the present invention is directed to a system. The system includes a Power Frequency broadcast station, a receiver, and a network. The Power Frequency broadcast station includes a transmitter and a server. The receiver is in communication with the Power Frequency broadcast transmitter and also includes a user interface for receiving user input commands comprising a request for information from the Power Frequency broadcast station.

[0062] The receiver is configured to establish a two-way communication path between the receiver and the Power Frequency broadcast transmitter. The network is in communication with the server and the receiver for exchanging information therebetween. The request for information is provided to the server via the network and the server is configured to receive the request and transmit a response message to the receiver in accordance with the request.

Continuously Outboard Recharged Electric Vehicle (COREY)

[0063] Given suitable infrastructure, permissions and vehicles, BEVs (battery electric vehicles) can be recharged while the user drives. The BEV establishes contact with an electrified rail, plate or overhead wires on the highway via an attached conducting wheel or other similar mechanism (see Conduit current collection). The BEV's batteries are recharged by this process—on the highway—and can then be used normally on other roads until the battery is discharged. Some of battery-electric locomotives used for maintenance trains on the London Underground are capable of this mode of operation. Power is picked up from the electrified rails where possible, switching to battery power where the electricity supply is disconnected.

[0064] The present invention is directed to overcome the disadvantages of the prior art. The invention is a mechanism which taps into the naturally occurring static electricity in the atmosphere. Whereas heretofore, the attempt to garner electricity from the atmosphere has focused exclusively on capturing lightning, the present invention syphons off the static electricity which is generated from any agitated air and voids lightning.

[0065] Lightning is only the final discharge of the static electricity, whether that lightning is intra-cloud lightning, cloud-to-ground lightning, or inter-cloud lightning. Other types of final discharges are known as heat lightning, summer lightning, sheet lightning, ribbon lightning, silent lightning, ball lightning, bead lightning, elves, jets, and sprites. Well before these discharges are observed, as the atmosphere becomes agitated by wind or thermal, static electricity is being generated. The present invention recognizes that this static electricity is being formed and creates a mechanism to capture it.

[0066] In the preferred embodiment, a sensor array is used to monitor the activities both at the base unit (such as electrical flow within the conductor) and in the surrounding locale. A sensor monitoring the electrical flow (i.e. voltage and/or current) within the conductor is used to monitor the electrical activity within the conductor.

[0067] In the preferred embodiment, a lightning sensor monitors for lightning activity within the locale. As noted earlier, the electrical characteristic of lightning is so extreme that ideally this discharge is avoided as it might damage the mechanism of this invention. The sensor array is utilized by a controller, such as microprocessor, programmed to operate the mechanism as outlined herein.

[0068] The controller operates the winch motor to extend or withdraw the conductive line and by extension the altitude of the balloon. The controller is programmed to operate the winch by monitoring the electrical characteristics of the conductor and adjusting the balloon's altitude to maintain these characteristics within the conductor within a preset range.

[0069] This preset range is established either in the base programming of the controller or is established by an operator of the system. As example, by controlling the amount of current being withdrawn from the atmosphere, the mechanism operates within a safe range and also provides a relatively stable current flow from which a variety of activities can take place (such as DC-AC conversion).

[0070] The controller also utilizes the lightning sensor to protect the mechanism from a lightning strike. Should lightning be detected within a pre-determined range (as established by the software or defined by an operator), then the balloon is pulled down to minimize the risk of damage from a lightning strike.

[0071] Another aspect of the invention relates to the electrical system which accepts the fluctuating atmospheric charge and changes it into an acceptable configuration for either the desired load or for the existing power grid.

[0072] Power grids in the United States operate with a frequency of 60 hertz in an alternating current arrangement. While this basic configuration seems to be universally accepted, the voltage within the grid varies dramatically, such as 15 kv, 34 kv, 69 kv, and even 112 kv.

[0073] Each atmospheric generator is placed proximate to or within easy access to a specific grid; this establishes the required electrical output configuration (i.e. that which is accepted by the power grid). As example, one of the atmospheric electrical collector units as described above collects the atmospheric electrical power as direct current and then supplies the appropriate power grid a specific flow (as example, AC, 60 hertz, at 69 kv).

[0074] The difficulty lies the fact that the DC current being garnered from the atmosphere varies depending on the actual agitation being generated in the atmosphere. This means that the source of DC current is fluctuating.

[0075] The present invention uses a monitoring system which checks the input DC voltage. Depending on the actual voltage being received, the appropriate converter is connected to the input DC voltage so that the desired output is obtained.

[0076] As example, suppose the DC input voltage is 1500 volts, the monitoring system, sensing this input, closes the switch connecting the DC voltage to a converter which accepts DC voltage in the range of 1000-2000 volts which then delivers an AC, 60 hertz 69 kv signal to the power grid. If the DC input voltage increases to 2100 volts, then the monitoring system opens the switch to the first converter (1000-2000 volts) and closes the switch to a second converter (such as 2000-4000 volts) to deliver the desired output of AC (60 hertz, 69 kv) for the power grid.

[0077] In this manner, regardless of the fluctuating input DC voltage, the electrical grid is supplied with a fully configured electrical input conforming to the needs of that specific electrical grid.

[0078] Another aspect of the present invention is the use of a tower or permanent structure instead of an aircraft. In this embodiment, the building or tower is electrically isolated from the ground and a rod (similar to a lightning rod) is extended into the atmosphere. The rod collects the atmospheric charge which is conveyed via an electrical conduit (ideally insulated) where the collected DC charge is reconfigured to meets the need of the locale.

[0079] In this context, for one embodiment of the invention, a tower is placed onto the top of a building. The tower is electrically isolated from the building using such mechanisms well known to those of ordinary skill in the art such as rubber mats. A rod ideally extends from the top of the tower to facilitate the collection of the DC electrical energy.

[0080] Piezoelectricity is a material property that is manifested when voltage is produced by applying mechanical forces, and vice versa, the effect has been described as direct and converse. Piezoelectricity has been described as coupling between a quasi-static electric field and dynamic mechanical motion.

[0081] A piezoelectricity converter mechanism such as described above, is connected to the tower to flow the DC electricity to a converter which modifies the DC current for the specific application. In one application, the DC current is converted to the electrical needs of the building, thereby providing at least some of the electrical requirements of the building itself.

[0082] As noted earlier, the dynamic converter system of the present invention allows a power generator to address a variable voltage in an efficient manner. This makes the dynamic converter system ideal for a variety of alternative energy sources such as the above described atmospheric electrical generator and other alternative energy sources such as wind and wave powered systems. In these systems, the energy being generated must be converted to a proper electrical configuration for a identified load. This may be a particular motor or connection to the power grid which act as a load to the power generating mechanism.

[0083] For these energy generating systems, the converter assembly of this invention utilizes multiple converters. Each converter is configured to accept a unique range of voltages and from these voltages, create the desired electrical configuration. By using multiple converters, a full range is available, from a minimum voltage input to a maximum voltage input.

[0084] The present invention can include systems and methods for integrating sensors for tracking atmospheric transducer system performance metrics into media devices and accessories therefor, thereby reducing or eliminating the need for additional independent monitoring devices. In one embodiment of the present invention.

[0085] It also is known to provide such transducers with connectors to allow their rechargeable batteries to be charged. In some cases, the connector is a Universal Serial Bus (USB) connector, allowing the transducer to be charged by plugging it into the USB port of a computer, grid circuit or other device.

[0086] These and other objects and advantages of the invention will appear more clearly from the following description in which the preferred embodiment of the invention has been set forth in conjunction with the drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

[0087] FIG. **1** Prior Art depicts perspective view of Electric currents created in sunward ionosphere;

[0088] FIG. **2** is a box flow chart of the propulsion cycle systems present invention;

[0089] FIG. **3** is an top view of the piezoelectric disk cylinder orb of the present invention;

[0090] FIG. **4** is a longitudinal sectional view showing an embodiment of this invention;

[0091] FIG. **5** is a top view of the (ATS) slip rotor piezoelectric chamber of the present invention;

[0092] FIG. **6** is an alternate top view of the piezoelectric cylinder orb of the present invention;

[0116] FIG. **34** is (ATS) cross section view of body embed panel device of the present invention.

DETAILED DESCRIPTION

[0117] This sequence of oscillations causes the conductive rotor within piezoelectric molded housing device to spin rapidly thereby winding the mechanism in a manner closely simulating the spinning of the conductive rotor that occurs during normal electric activity when the device is activated. Due to the forces that are exerted, the conductive rotor spins around the piezoelectric cylinder device shaft during the oscillations, as opposed to the partial rotation observed in prior art mechanisms. Therefore, the time required to charge the Atmospheric Transduction System (ATS) device, and the energy required, is substantially reduced. Moreover, since the rotor is spinning about the shaft, as opposed to merely being held in a downward position while the ATS device is rotated, recharging more closely approximating the design mechanism is achieved, thereby putting less wear on the ATS chamber device Innovative Piezoelectric housing and ball bearing, coupler and book spine stacks. There relies the notion of negative ground electricity and positive aerial electricity which is in abundance. This invention substantiates land vehicles recycle recharge by reverse oscillation. Aerial vehicles recycle recharge by forward oscillation in accumulation of environmental positive and negative electricity. These aforementioned activities are integral or synchronous with frequency.

[0118] Prior Art FIG. **1**

[0119] Electric currents created in sunward ionosphere. FIG. **2** is a recycle box flow chart **49** of a self propulsion unit consisting of a battery **27**, engine **29** and piezoelectric transducer **33** unit. FIG. **3** is a multiple disk **31** load part **51** about a 360 degree cylinder **45** and shaft **44**. FIG. **4** is a piezoelectric molded device **100** housing **110** containing a ball bearing race **104**, disk stacks capacitor **102** and conductive rotor **46**. FIG. **5** is a piezoelectric chamber **120** configuration including a counterweights **50**, shaft **44**, conductive slip rotor **106**. FIG. **6** is an alternate part **200** chamber cylinder **201** embodiment containing piezoelectric spine disk stack capacitors **102**. FIG. **7-10** are variations of spine **107**,**108**,**109**,**110** case piezoelectric stack capacitor **102** with plate and ball heads. FIG. **11** Various embodiments of the present invention, among others, will now be described with reference to the accompanying drawings. Accordingly, FIG. **11** illustrates an embodiment of a Atmospheric Transduction (ATS) System **300** architecture. The system **300** may include, for example, a satellite broadcast station **318** that transmits signals **333** containing frequency content from a geostationary satellite **312** by way of airplane antenna **326**. In turn, the satellite **312** transmits line-of-sight (LOS) signals **333** to one or more ATS terrestrial frequency power receiver farms **314**. The system **300** also may include one or more terrestrial repeaters **316** which receive and retransmit the satellite signals **333** as repeater signals **323** to facilitate reliable reception in geographic areas where LOS reception from the satellite **312** is obstructed by tall buildings, hills, tunnels, and other similar impediments to the signals **333**. The ATS receivers **314** maybe designed to receive one or more signals **333** from the satellite **312** and/or from the terrestrial repeater transceiver **316**. In operation, such ATS receivers **314** may receive both the satellite signals **333** and the repeater signals **323**. The receivers **314** also may be located in mobile environments **320**, **321**, **322** which include, but are not limited to, land vehicles **321**, **322**, aircraft **320**, watercraft **900**, and handheld devices, among others. The receivers **314** also may be fixed in stationary units for residential use (e.g., home **325**,**750** entertainment, etc.) or commercial **314**, **328**,**360** use (e.g., business **314**, office **700**, security **328**, etc.). The power frequency broadcast station **318** also may be in communication with a grid network **342**. Two-way communication between the ATS receivers **314** and the power frequency broadcast station **318** may occur via the network **342**. Furthermore, information feedback from the power frequency broadcast station **318** may be transmitted to the ATS receiver **314** both by way of the network **342** as well as via the satellite **312**. Information also may be transmitted to the power broadcast station **318** wirelessly via a wireless network **342**,**707** by way of transducer tower **360**.

[0120] Further disclosed in FIG. **12** and FIG. **13** (in block diagrams **400**, **500**) are electrical schematics for handling the static charge from the atmosphere. By maintaining the voltage being collected in a prescribed range, an electrical conversion system is easily designed. While FIGS. **12**, and **13** illustrate some electrical configurations, those of ordinary skill in the art readily recognize a variety of other configurations which will serve the same function.

[0121] Referencing FIG. **12**, Direct Current In (DC IN) **401** is buffered by a gang of capacitors **410** before being communicated to a DC/AC converter **420**. The DC/AC converter **420** converts the direct current into a an alternating current suitable for placement over an existing electrical grid **430** such as normally found from a power-plant. FIG. **12** Also illustrates an electrical arrangement suitable for use in charging a battery **440**. DC IN **401** is buffered by capacitor **410** bank before entering into a step down transformer **435**. Step down transformer **435** reduces the voltage so that the voltage can safely be introduced into battery **440** which is connected to ground **450** at the battery's other pole. In FIG. **12**, DC IN **401** is fed into an adjustable rheostat **460** which is controlled by the controller **465** so that the DC OUT **470** falls within a computer **475** monitored and sensor **480** specified range. FIG. **13** Hypothetically, unused energy may be recycled current **501** and/or recaptured by reversing the oscillated spin rotation of devices **51**, **100**, **120** with the use of a rectifier **502** and Step up transformer **503**, returned to grid **430** capacitor **410**. This theory lends itself to the concept of positive and negative frequency. FIG. **14-17** Self charging propulsion embodiment of the invention where Da Vinci's ball race **510**,**512** is combined with a disk cylinder **45** and **513** stack balls **525**, conductive rotor **46**, **511** tooth gear **515** and piezoelectric molded housing **555**. FIGS. **18** & **19** Improvement structures Franklin's lightening rod **600**,**603** and a molded vibration transducer **601** quasi replicating Vion's tubes and piezoelectric spine stacks capacitor **602** improving Tesla's Atmospheric transmit device. FIG. **20** is an atmospheric receiving building sub station **700** where energy is consumed and excess rendered to the grid **707** by conductive rotor **702** transducer **710**, tower transducer **703**, antenna rod **701** and transducer windows **704**.

[0122] FIG. **12** and FIG. **2** flowchart illustration also includes battery **440**. Battery **440** may provide electrical power to components of ATS devices within FIG. **11**. Charging circuitry may also be provided to charge battery **440** when an external power supply is connected to an ATS device **100**. FIG. **14-17** eliminates one or more steps by presenting a self charge retaining transducer **510-513** may be configured with an accelerator sensor **480** controller **465** and gears **515**, provide reciprocal power incorporated within piezoelectric molded and ceramic housing **555** along with stack balls **525** and cylinder **545**. This assembly more resembles a motor by characteristics given power with application.

[0123] In operation, as illustrated in FIGS. **2-20** and FIGS. **21-34**, is periodically energized by movement to rotate Orb in either a clockwise or counterclockwise direction. The length of time or activity is energized, and the length of time between the period when the capacitor **31**, **102** battery is energized, will depend on the particular ATS device design. As the Orb rotates, the outer end of the disk moves along a 360° circular pathway to push against with forward and rearwardly spinning. Upon engagement of the Orb, ATS device disk is rotated until carried to the apex or top of the circular pathway. Upon reaching the apex, the gravitational and vibrational force or counterweight **50** promotes additional oscillation. ATS device movement rapidly rotate on Orb at a rotational speed greater than the speed of rotation of Orb. Counterweight **50** is then carried beyond the bottom or lowest point of the pathway by its momentum to a point near the apex on the opposite side of the pathway. The cycle is repeated through multiple increasing oscillations of the ATS device until counterweight **50** stops at the bottom position, or until once again engages to again move counterweight to the top of its circular pathway.

[0124] FIG. **2** is a flow chart showing generation of energy using a rotor according to one or more of the above-described embodiments. First, battery **27** starts the engine **29** and/or mobile transducer **33** is oscillated. In response to this acceleration, forces are imposed on one or more rotation piezoelectric devices. In response to those forces, the piezoelectric devices output electrical energy, which energy is extracted at a power controller **465**. The power controller **465** sensor **480** then makes this energy available to recharge a capacitor **410** battery **440** and/or to electronic components of the mobile terminal. Although FIG. **2** shows a serial flow of events, it is to be appreciated that the events of blocks **33**, **27** and **29** occur substantially instantaneously upon acceleration of the mobile terminal.

Preferred Alternate Embodiments

[0125] The present invention (ATS) device in accordance with an embodiment of the present invention overcomes the foregoing problem in the conventional art and provides an electro energy vibration and alternative to gas, oil or fossil fuel consumption in FIG. **21** homes **750** transducer **755**, FIG. **28** airplane **880** transducer **801**, FIG. **27** train **860** transducer **801**, FIG. **32** auto **950** transducer **910**, FIG. **25** and FIG. **33** motorcycles **960**,**850** transducers **799**, **802**, **810**, **910** and FIG. **29** boat **900** transducers **901**,**910**.

[0126] In order to solve the foregoing problems in the conventional art, the present invention provides an electro transducer having a ball bearing assembly which is compatible with FIG. **26** axle shaft **44** transducer **810** wheel **870** assembly. In order to solve the foregoing problems in the conventional art, the present invention provides an electro transducer having an FIG. **34** housing panel **980** transducer **910** assembly which is compatible with an exterior body assembly. Thereby, an Atmospheric transducer device may be shock **800** integrated as within the FIG. **23** coupler **802**, and FIG. **24** ladder **799**, (vertical friction) piezoelectric absorbers assemblies. In order to solve the foregoing problems in the conventional art, the present invention provides an electro transducer having a capable flat assembly which is compatible with FIG. **22** window **704** disk **31** plate transducer **714**, FIG. **30** solar panel **920** transducer **910**, FIG. **31** wind turbine **930** transducer **910** assembly. This invention provided FIG. **3** piezoelectric plate disks **31**, FIG. **7-10** spine piezoelectric disks stacks **107-110** capacitor **102**, FIG. **17** piezoelectric stack balls **525** capacitor, the arrangement of balls **525** will not be in a facing relation. The deformation in the inner and outer races during rotation of the ball bearing while undergoing a radial load is made irregular and complicated. The spine eliminates the deformation and vibration level increased by a combination of ceramic and molded piezoelectric materials at a regular predetermined frequency thereby multiplying the level of vibration and noise reduction.

[0127] Certain modifications and improvements will occur to those skilled in the art upon a reading of the foregoing description. It should be understood that all such modifications and improvements have been deleted herein for the sake of conciseness and readability but are properly within the scope of the following claims.

[0128] Thus it is seen that an atmospheric transducer device may be integrated and/or provided. It will be understood that the foregoing is only illustrative of the principles of the invention, and that various modifications can be made by those skilled in the art without departing from the scope and spirit of the invention, and the present invention is limited only by the claims that follow.

1-3. (canceled)

4. An atmospheric transduction system comprising:

means for recycle recharge by oscillation and frequency in accumulation of environmental positive and negative electricity, maintaining the voltage being collected in a prescribed range, providing an electrical conversion broadcast network; and

means for collecting the atmospheric electrical power as direct current and then supplies the appropriate power grid, transceiver and capacitates a charge; and

means for self charging propulsion provides motor characteristics, and frequency engine.

5. The atmospheric transduction system in accordance with claim **1**, wherein said means for recycle recharge by oscillation and frequency in accumulation of environmental positive and negative electricity, maintaining the voltage being collected in a prescribed range, an electrical conversion broadcast network comprises piezoelectric transducer molded device(s), rotor, stack ball bearing, coupler, book spine stacks and antenna rod stacks;

wherein said means for collecting the atmospheric electrical power as direct current and then supplies the appropriate power grid and capacitates a charge comprises a piezoelectric network, piezoelectric grid, piezoelectric spine stack antenna, piezoelectric transmitters, piezoelectric receivers, piezoelectric devices, piezoelectric cylinders and orbs, power frequency broadcast;

wherein said means for charging providing motor characteristics, said power frequency engine comprises a sensor accelerator, rotor/gear, battery/capacitor, antenna, controller, for propulsion.

6. An atmospheric transduction system comprising:

a piezoelectric transducer molded device(s), rotor, spine ball bearing, coupler and book spine stack transducers, for recycle recharge by oscillation and frequency in accumulation of environmental positive and negative electricity, maintaining the voltage being collected in a prescribed range, providing an electrical conversion broadcast server network; and

a piezoelectric network, piezoelectric grid, piezoelectric spine stack antenna, piezoelectric transmitters, piezoelectric receivers, piezoelectric devices, piezoelectric cylinders and disc orbs, stack rods, power frequency broadcast, for collecting the atmospheric electrical power as direct current and then supplies the appropriate power grid, transceiver and capacitates a charge; and

a sensor accelerator, rotor/gear, battery/capacitor, controller, antenna, means for self charge propulsion providing motor characteristics, thereby an engine of power frequency.

WIKIPEDIA

Atmospheric physics

Atmospheric physics is the application of physics to the study of the atmosphere. Atmospheric physicists attempt to model Earth's atmosphere and the atmospheres of the other planets using fluid flow equations, chemical models, radiation budget, and energy transfer processes in the atmosphere (as well as how these tie into other systems such as the oceans). In order to model weather systems, atmospheric physicists employ elements of scattering theory, wave propagation models, cloud physics, statistical mechanics and spatial statistics which are highly mathematical and related to physics. It has close links to meteorology and climatology and also covers the design and construction of instruments for studying the atmosphere and the interpretation of the data they provide, including remote sensing instruments. At the dawn of the space age and the introduction of sounding rockets, aeronomy became a subdiscipline concerning the upper layers of the atmosphere, where dissociation and ionization are important.

Remote sensing

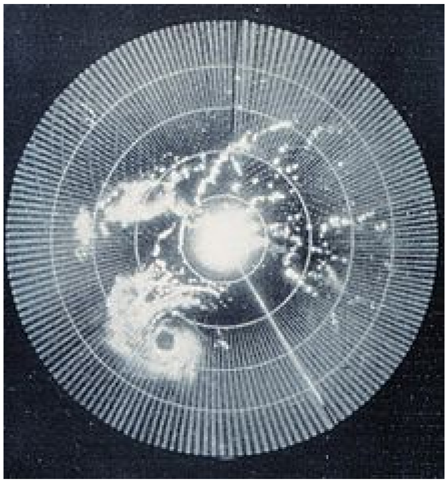
Remote sensing is the small or large-scale acquisition of information of an object or phenomenon, by the use of either recording or real-time sensing device(s) that is not in physical or intimate contact with the object (such as by way of aircraft, spacecraft, satellite, buoy, or ship). In practice, remote sensing is the stand-off collection through the use of a variety of devices for gathering information on a given object or area which gives more information than sensors at individual sites might convey.[1] Thus, Earth observation or weather satellite collection platforms, ocean and atmospheric observing weather buoy platforms, monitoring of a pregnancy via ultrasound, Magnetic Resonance Imaging (MRI), Positron Emission Tomography (PET), and space probes are all examples of remote sensing. In modern usage, the term generally refers to the use of imaging sensor technologies including but not limited to the use of instruments aboard aircraft and spacecraft, and is distinct from other imaging-related fields such as medical imaging.

There are two kinds of remote sensing. Passive sensors detect natural radiation that is emitted or reflected by the object or surrounding area being observed. Reflected sunlight is the most common source of radiation measured by passive sensors. Examples of passive remote sensors include film photography, infra-red, charge-coupled devices, and radiometers. Active collection, on the other hand, emits energy in order to scan objects and areas whereupon a sensor then detects and



Brightness can indicate reflectivity as in this 1960 weather radar image (of Hurricane Abby). The radar's frequency, pulse form, and antenna largely determine what it can observe.

measures the radiation that is reflected or backscattered from the target. radar, lidar, and SODAR are examples of active remote sensing techniques used in atmospheric physics where the time delay between emission and return is measured, establishing the location, height, speed and direction of an object.[2]

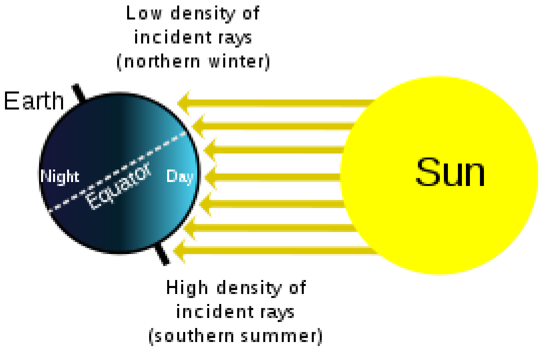
Remote sensing makes it possible to collect data on dangerous or inaccessible areas. Remote sensing applications include monitoring deforestation in areas such as the Amazon Basin, the effects of climate change on glaciers and Arctic and Antarctic regions, and depth sounding of coastal and ocean depths. Military collection during the cold war made use of stand-off collection of data about dangerous border areas. Remote sensing also replaces costly and slow data collection on the ground, ensuring in the process that areas or objects are not disturbed.

Orbital platforms collect and transmit data from different parts of the electromagnetic spectrum, which in conjunction with larger scale aerial or ground-based sensing and analysis, provides researchers with enough information to monitor trends such as El Niño and other natural long and short term phenomena. Other uses include different areas of the earth sciences such as natural resource management, agricultural fields such as land usage and conservation, and national security and overhead, ground-based and stand-off collection on border areas.[3]

Radiation

Atmospheric physicists typically divide radiation into solar radiation (emitted by the sun) and terrestrial radiation (emitted by Earth's surface and atmosphere).

Solar radiation contains variety of wavelengths. Visible light has wavelengths between 0.4 and 0.7 micrometers.[4] Shorter wavelengths are known as the ultraviolet (UV) part of the spectrum, while longer wavelengths are grouped into the infrared portion of the spectrum.[5] Ozone is most effective in absorbing radiation around 0.25 micrometers,[6] where UV-c rays lie in the spectrum. This increases the temperature of the nearby stratosphere. Snow reflects 88% of UV rays,[6] while sand reflects 12%, and water reflects only 4% of incoming UV radiation.[6] The more glancing the angle is between the atmosphere and the sun's rays, the more likely that energy will be reflected or absorbed by the atmosphere.[7]



This is a diagram of the seasons. In addition to the density of incident light, the dissipation of light in the atmosphere is greater when it falls at a shallow angle.

Terrestrial radiation is emitted at much longer wavelengths than solar radiation. This is because Earth is much colder than the sun. Radiation is emitted by Earth across a range of wavelengths, as formalized in Planck's law. The wavelength of maximum energy is around 10 micrometers.

Cloud physics

Cloud physics is the study of the physical processes that lead to the formation, growth and precipitation of clouds. Clouds are composed of microscopic droplets of water (warm clouds), tiny crystals of ice, or both (mixed phase clouds). Under suitable conditions, the droplets combine to form precipitation, where they may fall to the earth.[8] The precise mechanics of how a cloud forms and grows is not completely understood, but scientists have developed theories explaining the structure of clouds by studying the microphysics of individual droplets. Advances in radar and satellite technology have also allowed the precise study of clouds on a large scale.

Atmospheric electricity

Atmospheric electricity is the term given to the electrostatics and electrodynamics of the atmosphere (or, more broadly, the atmosphere of any planet). The Earth's surface, the ionosphere, and the atmosphere is known as the **global atmospheric electrical circuit**.[9] Lightning discharges 30,000 amperes, at up to 100 million volts, and emits light, radio waves, x-rays and even gamma rays.[10] Plasma temperatures in lightning can approach 28,000 kelvins and electron densities may exceed $10^{24}/\text{m}^3$.[11]

Cloud to ground Lightning in the global atmospheric electrical circuit.

Atmospheric tide

The largest-amplitude atmospheric tides are mostly generated in the troposphere and stratosphere when the atmosphere is periodically heated as water vapour and ozone absorb solar radiation during the day. The tides generated are then able to propagate away from these source regions and ascend into the mesosphere and thermosphere. Atmospheric tides can be measured as regular fluctuations in wind, temperature, density and pressure. Although atmospheric tides share much in common with ocean tides they have two key distinguishing features:

i) Atmospheric tides are primarily excited by the Sun's heating of the atmosphere whereas ocean tides are primarily excited by the Moon's gravitational field. This means that most atmospheric tides have periods of oscillation related to the 24-hour length of the solar day whereas ocean tides have longer periods of oscillation related to the lunar day (time between successive lunar transits) of about 24 hours 51 minutes.[12]

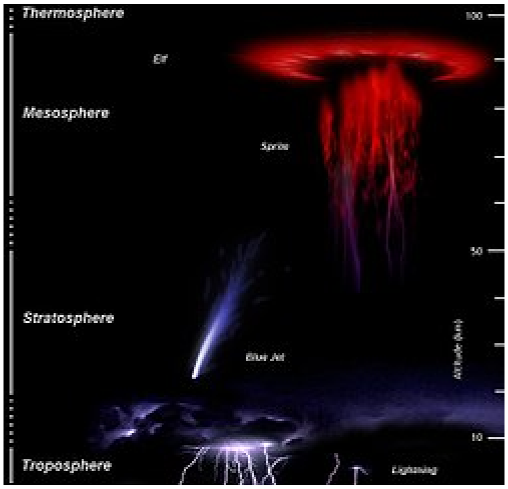
ii) Atmospheric tides propagate in an atmosphere where density varies significantly with height. A consequence of this is that their amplitudes naturally increase exponentially as the tide ascends into progressively more rarefied regions of the atmosphere (for an explanation of this phenomenon, see below). In contrast, the density of the oceans varies only slightly with depth and so there the tides do not necessarily vary in amplitude with depth.

Note that although solar heating is responsible for the largest-amplitude atmospheric tides, the gravitational fields of the Sun and Moon also raise tides in the atmosphere, with the lunar gravitational atmospheric tidal effect being significantly greater than its solar counterpart.[13]

At ground level, atmospheric tides can be detected as regular but small oscillations in surface pressure with periods of 24 and 12 hours. Daily pressure maxima occur at 10 a.m. and 10 p.m. local time, while minima occur at 4 a.m. and 4 p.m. local time. The absolute maximum occurs at 10 a.m. while the absolute minimum occurs at 4 p.m.[14] However, at greater heights the amplitudes of the tides can become very large. In the mesosphere (heights of ~ 50 – 100 km) atmospheric tides can reach amplitudes of more than 50 m/s and are often the most significant part of the motion of the atmosphere.

Aeronomy

Aeronomy is the science of the upper region of the atmosphere, where dissociation and ionization are important. The term aeronomy was introduced by Sydney Chapman in 1960.[15] Today, the term also includes the science of the corresponding regions of the atmospheres of other planets. Research in aeronomy requires access to balloons, satellites, and sounding rockets which provide valuable data about this region of the atmosphere. Atmospheric tides play an important role in interacting with both the lower and upper atmosphere. Amongst the phenomena studied are upper-atmospheric lightning discharges, such as luminous events called red sprites, sprite halos, blue jets, and elves.



Representation of upper-atmospheric lightning and electrical-discharge phenomena

Centers of research

In the UK, atmospheric studies are underpinned by the Met Office, the Natural Environment Research Council and the Science and Technology Facilities Council. Divisions of the U.S. National Oceanic and Atmospheric Administration (NOAA) oversee research projects and weather modeling involving atmospheric physics. The US National Astronomy and Ionosphere Center also carries out studies of the high atmosphere. In Belgium, the Belgian Institute for Space Aeronomy studies the atmosphere and outer space.

by Kellie

The below added text I have been looking into has been an easily made design. Our government goes to no end to stop men and women who help human kind with their awesome God given inventions. I am not afraid to share this as Alex does with his knowledge and research. It is to open the minds of those that are dumbed down by corporate America and the global elite to do as they bid…No…stand up and fight against their system.

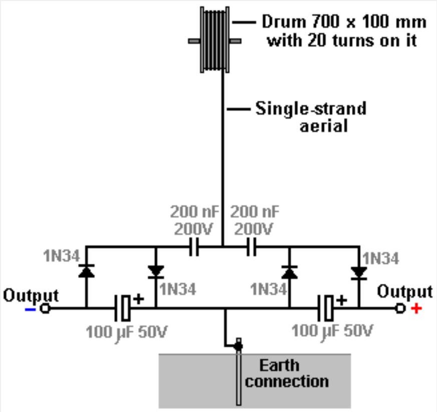
Free energy is NOT a hoax as they want you to believe.

If you have any engineer in you or technical expertise – Read…It works !

Jes Ascanius’ Version of Nikola Tesla’s Aerial System

This sort of information may seem confusing and maybe a little too technical for you, so let me tell you about the practical and useful applications used by Jes Ascanius, a Danish developer, to whom thanks is due for sharing his design. Initially, he set up a system to charge his mobile phone battery overnight from an aerial. Then he went on to produce a full-size Tesla Aerial System as described at the start of this chapter. Let’s start with the very simple system and progress from that to the more powerful arrangements.

The initial circuit uses one strand of solid wire which rises vertically to a 700 mm diameter drum where there are some twenty turns. The arrangement is like this:



The aerial wire is several metres long, and in the prototype, was supported by (and insulated from) the eaves of a house. The aerial should be vertical or near vertical and a proper earth connection provided by driving a metal rod into the ground or connecting a wire to a metal plate and burying the plate in the ground as a good electrical connection is needed here. The earth connection used here is a 12 mm copper pipe 3 metres long, driven into the ground and the ground around it saturated with water:

The wire used to connect with the earthing rod is very important and should not be less than 8 swg copper wire, that is, 4 mm diameter and 13 sq. mm. cross-sectional area. As with all free-energy devices, the exact constructional details are vital.

The diodes used are germanium 1N34 or 1N34a as germanium diodes drop far less voltage than do silicon diodes and the 1N34 types are low-loss diodes, particularly suited to this application. Ceramic disc types are recommended for the 200 nF capacitors. The prototype build looked like this:

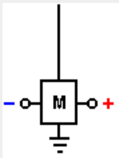
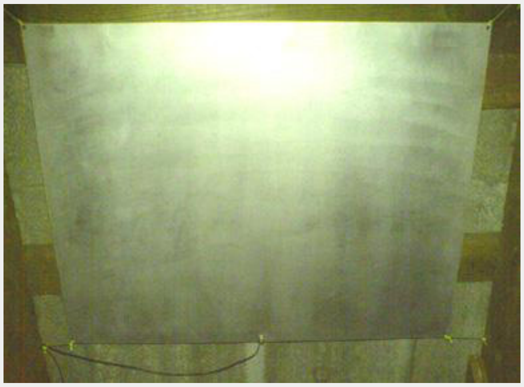
Now, consider this circuit as described, to be one modular building block which can lead to unlimited power from an aerial. I will represent the circuit shown above as a rectangle, showing the above circuit as:

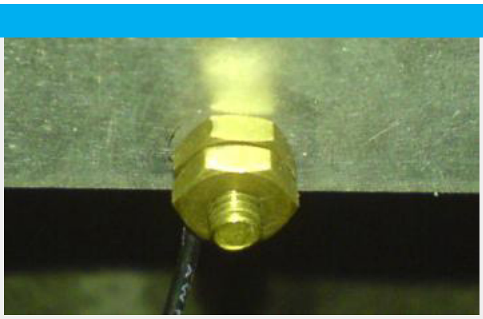


While it is possible to use more than one module with the aerial to get more power, the Danish developer then switched to the full-blown Tesla arrangement by attaching a 800 x 600 x 2 mm aluminium plate inside the sloping roof of his house:



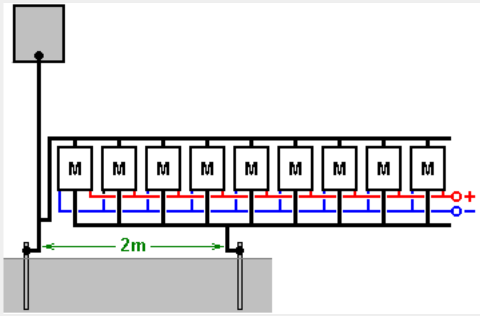
The plate being suspended using nylon cord to prevent it touching the roof or anything else:

The plate is positioned between 3 and 3.5 metres (10 to 12 feet) above the ground and the attachment to the plate is also heavy-duty 8 swg cable:



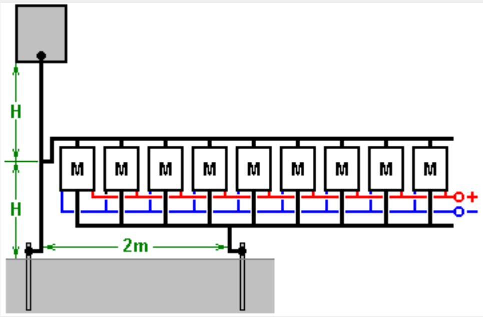
The cable is connected to the aluminium plate using a brass bolt and nuts which the builder thinks may be significant, quite apart from avoiding any galvanitic connection to the circuit. The cable is then run vertically downwards to the circuit. For this arrangement a second earthing point is also used. This is a galvanised iron pipe 3 metres long, driven vertically into the ground which is saturated with water. The second earth is 2 metres away from the first earth.

This arrangement provides serious power, enough to cause injury to, or kill a careless human. With two modules, it will light an LED very brightly, driving it to 2.6 volts. If the LED is removed, then the voltage climbs to about twenty volts and is easily sufficient to charge a 12V battery or battery bank although that takes time. With twenty modules as 12V battery can be charged over night. It is estimated that with two hundred modules, the power would be sufficient to power a household although that has not yet been done. It should be borne in mind that each module is easy and cheap to make, so arranging for a stack of them where additional modules can be added at a later date for more power, is an ideal arrangement. The circuit is like this:



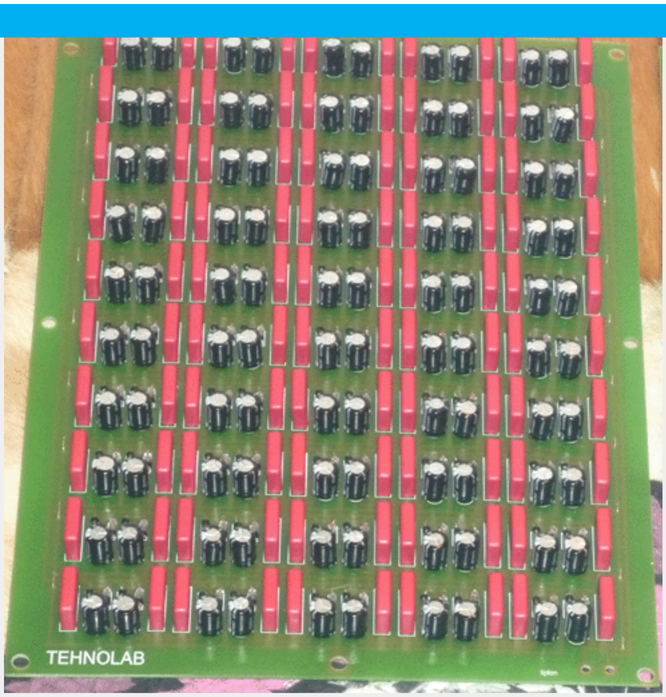
This circuit looks completely mad as the aerial input to the circuit appears to be directly short-circuited by the second earth connection. In spite of this, the circuit works very well when connected this way. Additional modules can be added without any known limit. Increased power can be had by either raising the aluminium plate higher above the ground, to say, 10 metres (33 feet), or by adding one or more additional aerial plates. As you have a good aerial connected through to a very good earth, there has to be the possibility of the equipment being hit by lightning, and so it is suggested that a protective spark-gap is installed between the aerial and the earth, close to the circuit, so that if high-voltage is suddenly applied to the aerial, the spark gap will fire and shunt the excess power through to the earth. Alternatively, possibly a better solution is to install a standard lightning rod system a few metres away from the aerial and a metre or two higher up, so that it forms a more attractive point for a lightning strike.

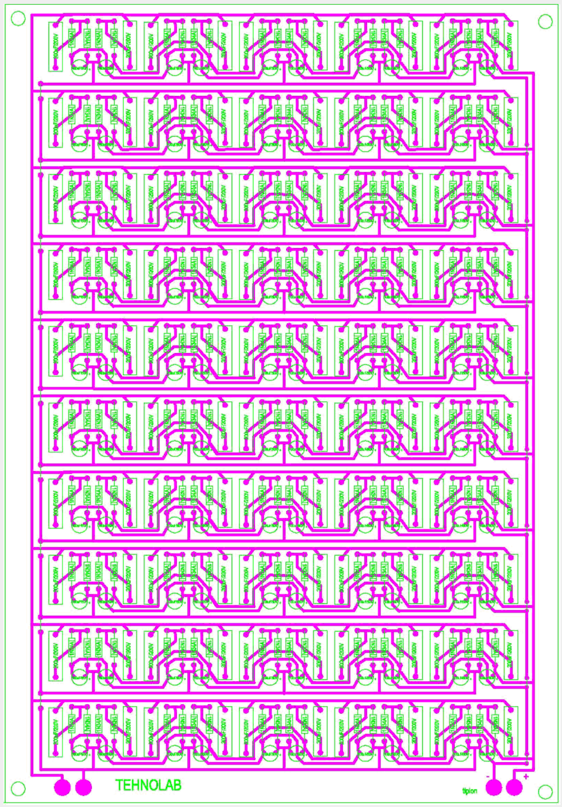
Further experimentation has shown that altering the connection point for the aerial has a significant effect on the results. If the connection is made at the mid point between the aerial plate and the earth connection, it produces a greater output:



With this arrangement a single module produces around 30 volts while the original method of connecting near the earth was giving about 26 volts with two modules.

Dragan Kljajic has been experimenting with this circuit and has started by building many of these modules on a printed circuit board like this:





Using two of these boards, Dragan is pulling 96 watts continuously from his aerial plate. He intends to extend this arrangement much further, but is being hindered at present by a local civil war.

There is a forum where some builders of this system share comments. One comment is that there is an increased risk of a lightning strike where you have an earthed aerial, and so it is advisable not to place the aerial plate inside a house, but perhaps suspended between two trees. Also, using a car spark plug connected across the module set can protect against lightning strikes damaging the circuitry.

Hello, I am new to this website and I am trying to build this things right now with the pcb. Has anyone successfully built this things with the PCB that Dragan make ?

THank you

cool. I remember reading an article about a farmer who was able to light a bunch of bulbs from a really long cable that somehow just inducted energy… this was after that idiotic show “Mythbusters” said it was impossible.. so, yeah. I don’t recommend that show.

I have made two of these boards but in A4 size with 32 modules on each board im in the process of drilling holes.
The alexkor circuit in Chap 7 is also worth looking at I will let you know when Im done with the Tesla /Jes Ascanius
circuit and what results I get I know its important to polish the plate and to have a very good earthing plate.

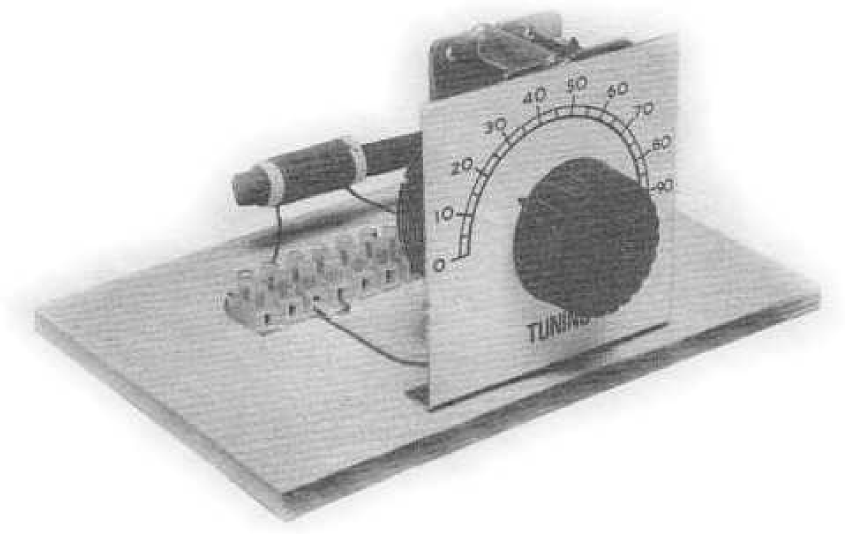
CRYSTAL SETS 5: EXPERIMENTAL CRYSTAL SETS



Picture 1 - The Complete Experimental Crystal Set

THE POPULARITY of the crystal radio arises from its simplicity, and the fact that it needs no power supply. The circuit here allows for easy experiments with tuning, aerial and diode coupling, and frequency coverage. Wrong connections can cause no damage to any components.

A Crystal Set is more often than not used for the reception of medium and long wave radio, but short wave reception is also quite feasible. It will normally be possible to receive some of the stronger international radio stations.

This is adapted from an article that appeared in the 1970's in Everyday Electronics, and gave me almost endless hours of fun!

BASIC CIRCUIT

The basic circuit is shown in Picture 2 below. The coil L1 can be air cored, or have a ferrite rod placed in its winding. The variable capacitor C1, in conjunction with aerial-earth capacitance, tunes the circuit to resonate with the wanted radio station frequency. The diode D1 "detects" or demodulates the radio signal so that the programme is heard in the earpiece.

This basic circuit can be modified in various ways to obtain better performance.

EARPHONE

As most constructors will be using a Crystal Earpice to listen to the crystal set it is essential that a 47k Ohm resistor is connected across the earphone terminals (TB1/1 and TB1/2 in the diagram), i.e. in parallel with the earphone, otherwise results will be very quiet.

A High Impedance headset of 20k Ohms (20,000 Ohms) may give even better results, but these are very difficult to obtain , so unless you happen to already own such a headset the Crystal Earphone with 47k resistor will be the only option. An ordinary magnetic earpiece or Walkman headphones will not work with a crystal set.

ASSEMBLY

Construction is of a 'breadboard' type using a wooden board of about 165 x 130 mm. A 12-way block connector, TB1, is used to connected together the components and this is screwed onto the wooden board. The use of a block connector provides an easy method of connecting the components together and then subsequently rearranging them as the experiments progress.

Tuning capacitor C1 is screwed to a bracket made of some scrap metal which is then also screwed firmly down to the baseboard, see Picture 1 above. Thin plywood screwed to the front edge of the baseboard would also provide a suitable method of fixing the tuning capacitor to the base. A knob with pointer is fitted to C1, and a scale is drawn and fitted behind this.

Except for C1, all connections are made by the terminals of the 12-way terminal block as shown in Picture 4. Loosen the screws with a small screwdriver, insert the bared ends of the wires, and tighten the screws. The various locations on the terminal block, TB1, are also shown in the circuit diagram, Picture 2.

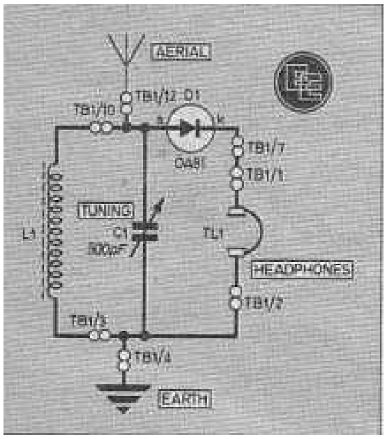
AERIAL AND EARTH

Crystal receivers need a long wire aerial preferably strung outside and about 25m long, or as long as is possible to install. If this is outside it should be high and clear of earthed objects as this will improve performance.

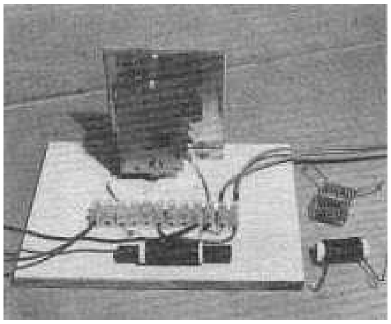
An earth is absolutely essential for a crystal set to work properly. The earth lead can be run to an earth rod or spike that is buried to a depth of about 1 meter into damp soil. Or it may be soldered to a bare metal can which is buried in damp soil.

It is feasible, though not recommended, that the earth lead can be connected to the earthing terminal of a hi-fi system or even to the bare metal case of a personal computer that is plugged into an earthed mains outlet, but is switched OFF.

Stranded, insulated wire, or purpose made aerial wire can be used for the aerial and earth leads.



Picture 2 - The Basic Circuit



Picture 3 - Photo Of The General Layout

INDUCTORS (The Tuning Coils)

The following four coils are suggested for initial use as L1 :

Coil 1: Make a thin card tube to slide on a 10mm diameter ferrite rod, and on this tube wind about 105 turns of 32 s.w.g. enamelled copper wire, side by side. Secure ends with sticky tape.

Coil 2: Make a similar coil to to coil 1 having about 15 turns of 24 s.w.g. enamelled wire on the card tube. Loops of cotton will help hold the ends in place.

Coil 3: Wind 9 turns of 20 s.w.g. bare tinned copper wire on an object about 20mm in diameter. Remove and stretch to separate the turns, to obtain a coil about 25mm long.

Coil 4: Make a similar coil to coil 3, but with 5 turns.

The Ferrite Rod

It will be necessary to have a ferrite rod of about 60mm to 75mm long available. Coils 1 and 2 will provide reception of medium wave and the longer short wave bands. Coil 3 should cover about 3 - 10MHz shortwave with the ferrite placed in it, or about 6 - 18MHz with the ferrite rod removed. Coil 4 should cover about 6 -13MHz with the rod in, and about 9 - 20MHz without the' rod.

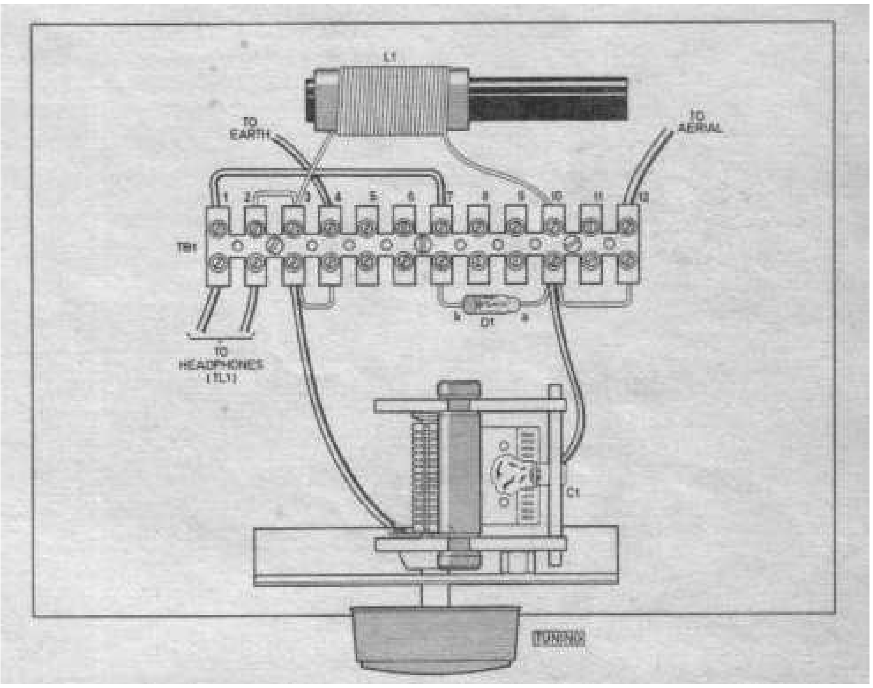
It will be noted that as the ferrite rod is inserted, any particular signal has to be re-tuned by opening Cl. This arises because the ferrite increases the inductance of the winding, so less parallel capacitance is needed for the same resonant frequency.

EFFICIENCY CHECKS

Tune in a m.w. transmission using coil 1 which gives good headphone volume. Place a microammeter or multi-range meter on a sensitive range in series with the headphones. A reading of 50-100uA or more may be obtained, depending on aerial, earth, earphone resistance and resistor value, coil and detector efficiency and strength of signals at your locality.

Placing the ferrite rod in the coil and re-tuning should boost the meter reading to some extent. Surplus or other detector diodes can be tried by substituting them in turn and noting the meter reading. Improvements to the aerial (or earth) will also show up as a rise in meter reading.

If experimenting with a crystal earpiece, which gives no direct current circuit, the meter may be clipped across the phone leads, i.e. D1 cathode to earth.



Picture 4 - Baseboard Layout Of The Crystal Set

AERIAL COUPLING

The aerial loads the tuned circuit heavily when connected directly to the top of the tuned circuit, as in Picture 2. This damps the tuning action and it can be found that stations spread out all over the dial, which is unsatisfactory.

The series capacitor, C2 connected in Picture 5(a) reduces the loading and thus improves the sharpness of the tuning. A variable or pre-set capacitor of about 250pF maximum is most suitable. for this role, though it is possible to experiment with a variety of fixed value capacitors in this range also.

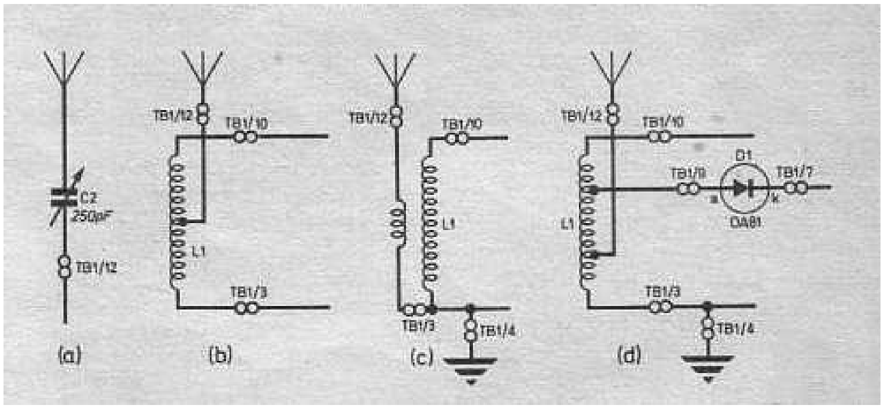
Connecting the aerial to a tapping on the coil, as in Picture 5 (b) also sharpens tuning. It may also increase volume. Try about 2 turns from earth for coil 4, or 4 turns from earth for coil 3.

Another method is to have a coupling primary, as in Picture 5 (c). This consists of a second coil, with about one third the turns of the original wound on top of the existing coil.

You can even combine these methods to find what arrangement best suits the aerial in use.

The diode can be disconnected from the end of L1 and taken to a spare position on TB1 for example location TB1/9. You can then run a flying-lead fitted with a crocodile clip from this position, connecting it to various tappings on the coil as required as in Picture 5 (d). This method also reduces loading on the tuned circuit.

Coils with spaced turns of bare wire are readily tapped. For other coils, small loops can be made every ten turns or so, and crocodile clips can be attached to these when selecting tapping points.



Picture 5 - Alternative Methods Of Aerial Coupling

SHORT WAVES

For shortwave reception, a good efficient outdoor aerial is certainly recommended. Evening listening in the region around 5 - 9MHz in often proves to be the most fruitful.

Since there is no amplification, as with a valve or transistor receiver, certain frequencies will seem to be completely dead at particular times of day. So if the crystal receiver works satisfactorily on medium wave and longwave, but no shortwave signals are heard, check again in the evening, or after dark, when conditions are different.

PARTS REQUIRED

C1	**365pF or 500pF Air Spaced Tuning Capacitor**
D1*	**OA47, IN34, OA81, OA90, OA91, IN94 or similar point contact small signal Germanium Diode** ***** The OA47 will be of particular interest since it has the lowest forward bias voltage of any of these diodes which will make the crystal set somewhat more sensitive and therefore louder. The US equivalent of the British OA47 is the IN34.
TL1	**High Impedance Headphones (20,000 Ohms)** **or Crystal Earphone**
TB1	**12-Way Plastic Screw Block Terminal**
Also Required:	**47 k Ohm Resistor for Crystal Earphone: Enamelled Copper Wire: 32 and 24 s.w.g. for L1: 20 s.w.g. tinned wire for L1: Ferrite Rod 10mm diameter x 75 mm long: 25m of wire for aerial: Wire and rod or spike etc for earth: Wood for base e.g. 10mm x165mm x 130mm: Scrap of metal of thin plywood for C1 bracket/front panel: Knob: Crocodile clip(s)**

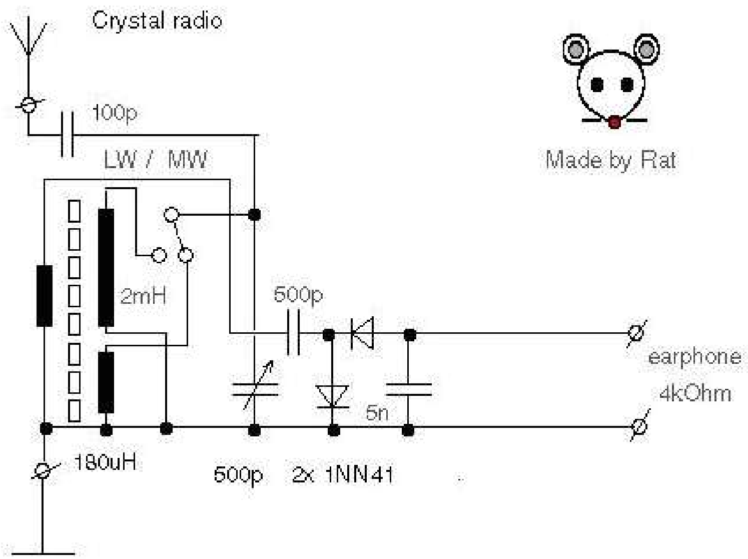
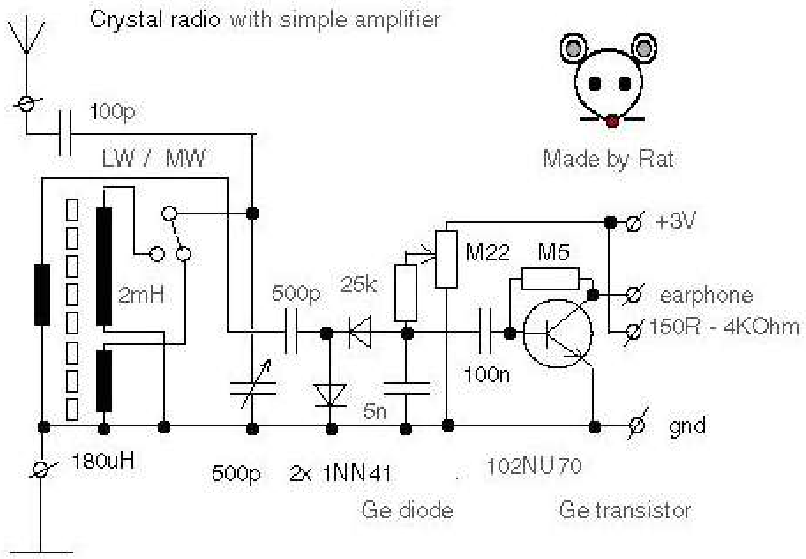
HERE ARE A COUPLE OF VERY INTERESTING CRYSTAL SET DESIGNS SENT IN BY KRYSATEC - "THE RAT" - FROM THE CZECH REPUBLIC



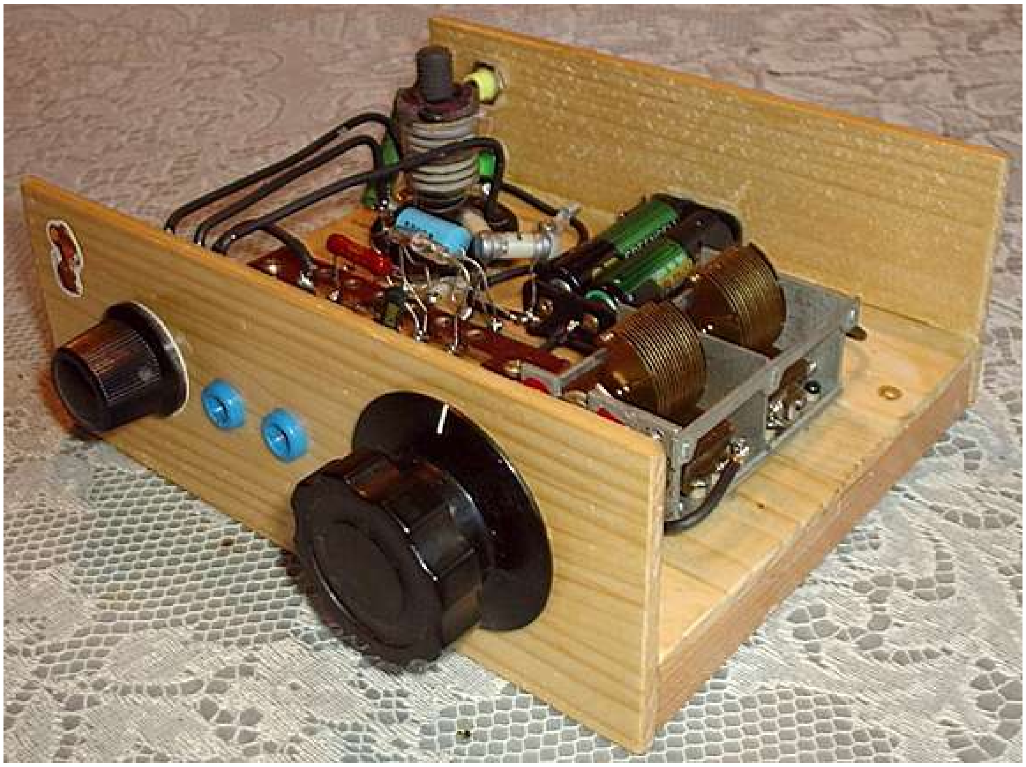
Crystal radio
100p
LW / MW
Made by Rat
2mH
500p
earphone
4kOhm
5n
180uH
500p
2x 1NN41

1/ Using old coils from old bulb radio for MW and LW band. Though it would be straightforward to wind the coils - one for Long Wave, one for Medium Wave and a coupling coil. Variable capacitor is 2 x 500pF only one half is used: 500pF. For the crystal earphone a resistor of about 82k ohm in parallel is required. This set also uses two Ge diodes as a multiplier in the quest for for higher audio signal output.



Crystal radio with simple amplifier
100p
LW / MW
Made by Rat
+3V
M22
M5
2mH
500p
25k
earphone
150R - 4KOhm
100n
5n
gnd
180uH
500p
2x 1NN41
102NU70
Ge diode
Ge transistor

2. If signals are not strong signal in your location, then the above circuit design can be considered. A simple transistor amplifier is used. A variable resistor M22 is used for better sensitivity which can be adjusted for poor signals. This crystal radio is aversion from cca 1960 - 1970 y.



Rat's finished Crystal Set with additional amplification - very neat!

'Minilabs' Crystal Radio

BELOW: Ian Tomlinson kindly sent in a photograph of the box that contained the kit for his John Adams Toys 'Minilabs' Crystal Radio.

It is a very simple circuit consisting of the coil (inductor) with a sliding contact that provides variable tapping points, a diode and crystal earphone. All that is added is the aerial and earth. There is no variable tuning capacitor for simplicity and to keep costs down.

The coil provides the inductance required for tuning into a certain frequency (wavelength). These days a variable "tuning" capacitor is normally wired in parallel across the inductance (coil) in order to vary the resonance of the tuned circuit and therefore enable to easily tune into various transmitters on different frequencies. This crystal is tuned varying the number of turns on the coil (ie varying the inductance) by tapping off at different points using the sliding contact ("ball").

The crystal earpiece, or high Z headphone, is connected between the output of the detector diode (the other end from the coil) and earth. The volume from a crystal earpiece may be considerably improved by connecting a resistor of - somewhere between - 4.7 k and 47k ohms in parallel with the earpiece. A crystal earpiece cannot directly allow current to flow through it and the parallel resistor therefore allows current to better flow through the circuit.

'Minilabs' crystal set by John Adams Toys

A discussion on configurations for Crystal Sets by Felix Scerri VK4FUQ

This discussion, by Felix Scerri VK4FUQ, was posted at this address which no longer appears on the web www.tarc.org.au/techinfo2.htm (error 404) so here it is reproduced:

Crystal Set design is one of my passions closely allied with my obsession for audio and high fidelity.

My main interest in crystal sets, apart from the wonder of a radio receiver that does not require a power source, is the potential excellence of the recovered audio quality from normal AM broadcast stations.

Personally, it is one of my great laments that most people have never heard how good wideband AM can sound. A high performance crystal set or similar TRF approach is, in my opinion,the only way to do it. There are a few people around who have heard the audible results of my efforts,and can only agree.

I have often wondered,given the ultimate simplicity of the crystal set, being essentially a tuned circuit,a diode detector and some form of output device, what it takes to achieve optimum performance. What follows are my thoughts on the matter.

Crystal Set optimisation, is in my opinion, all about reduction of circuit losses. Essentially this means high "Q" tuned circuits and high quality detectors. Efficient output devices also help too. But as we will see, there are some trade-offs required as well. A high "Q" tuned circuit is always benefical, as a high "Q" tuned circuit has lowest RF losses,highest potential selectivity,and highest voltage at resonance, which is very useful for the diode being fed from the tuned circuit. Variable capacitors, even the "modern" miniature variable capacitors (although the older air dielectric units, as used in old valve receivers are more desirable) for various reasons,are generally quite efficient, and a higher "Q" coil will produce the most worthwhile improvements.The best (highest "Q") coils are wound with "Litz" wire, which is a multistranded woven wire with all strands insulated from each other. The performance of Litz wire wound coils is spectacular, unfortunately, although I know Litz wire is still being made, from personal experience, it is VERY rare in Australia.

Efficient coil design can be quite complex and all my coils are wound on ferrite rods. There seems to be,at least for ordinary single wire windings (close wound), an optimum wire thickness for optimum coil "Q". I have determined .315 mm winding wire to be about optimum for simple (single wire) coils on ferrite rods. Thicker wire is NOT better, believe it or not.

Lacking Litz wire, an interesting winding approach I have developed is to use two slightly thinner wires wound as a bifilar winding connected together at the beginning and end of the coil, yields considerably higher "Q" compared to a simple single wire winding. I have found 0.25 mm winding wire optimum in this application.

Whilst high "Q" coils are beneficial from the RF point of view, there is a possible downside. If one is interested in maximum selectivity and sensitivity, there is no problem, but remember highest "Q" results in a narrowed audio band-width as a simple consequence of band-width. For high fidelity applications this could be a disadvantage under some circumstances, although there are clever ways around this.

Regardless of ultimate coil "Q", selectivity is a major issue with crystal sets generally. Here another trade-off is evident. For the maximum voltage into the diode, connecting the diode to the high impedance end of the coil (i.e. the top) yields the greatest voltage but the selectivity is usually terrible, because of severe "loading" by the diode circuit. For this reason, tapping well own the coil improves selectivity at the expense of signal volume (reduced voltage). Once again there are ways around this. As described in my "Double Tuned Crystal Set Tuner" article in "Amateur Radio" magazine, March 2002, the use of two separately tuned coupled resonant circuits allows top connection into the diode without compromising overall selectivity, thanks to the use of a second tuned circuit which is fed from the external antenna. The whole network forms a double tuned input bandpass filter and in practice this approach works very well. For single coil crystal sets I recommend the use of an un-tuned "antenna" winding adjacent to the "hot" end of the main coil, preferably adjustable (old paper reels from sewing cotton threads are ideal). This allows the degree of coupling to be optimised under actual listening conditions. The double tuned set up is best, yielding superb selectivity, but the un-tuned antenna coil arrangement also works quite well, especially if the diode is tapped well down the main coil.Tapping halfway works well.

The other method of performance improvement involves the use of the most effective detector system possible. Here things get very interesting. In fact the temptation is to use more complex circuitry, but that gets away from the charming simplicity of the crystal set. As an example, my own crystal set tuner has at times mutated into a TRF tuner complete with FET RF preamplifiers, active(powered) detectors and other enhancements. These modifications do work well, but loses the simplicity of a basic crystal set. In actuality, a simple diode detector can work extremely well, subject to some qualification. Diodes like to work with a reasonable level of RF input voltage. Audio distortion can result under conditions of low signal level, due to diode transfer curve non linearity and other factors, such as the widespread use of broadcast station "processing". The actual type of diode makes a difference. The 1N34A germanium diode is very popular for crystal set use, although in my experience just about ANY germanium diode will work, although it is worth trying different specimens. Some are definitely better than others. Even from a pack of twenty 1N34A's from the same source, some were definitely better than others. Measuring the average value of rectified output voltage across the diode load resistor will show which diodes are best. By the way, I regard a diode load resistor as being mandatory. I find a value of about 47K about right, especially if a crystal earpiece is being used or the crystal set is being used as a tuner feeding an audio pre-amplifier and following amplifier. If using high impedance magnetic type headphones, the headphones provide the diode DC load.

Another type of diode that is very interesting, is the hot carrier diode. There seem to be a lot of different hot carrier diodes around these days. There are even hot carrier diodes now being sold as "germanium diode equivalents". I have tried them and they do work acceptably well, but they are not quite as good as genuine germanium diodes such as the 1N34A. Typical UHF mixer hot carrier diodes, such as the 1N5711 will not work well in crystal set service simply because their "turn on voltage"is too high, similar to silicon diodes such as the 1N4148/914 series, which require a lot of RF input to function adequately as RF detectors, however a simple technique can be used to turn hot carrier diodes such as the 1N5711 into superlative detectors.

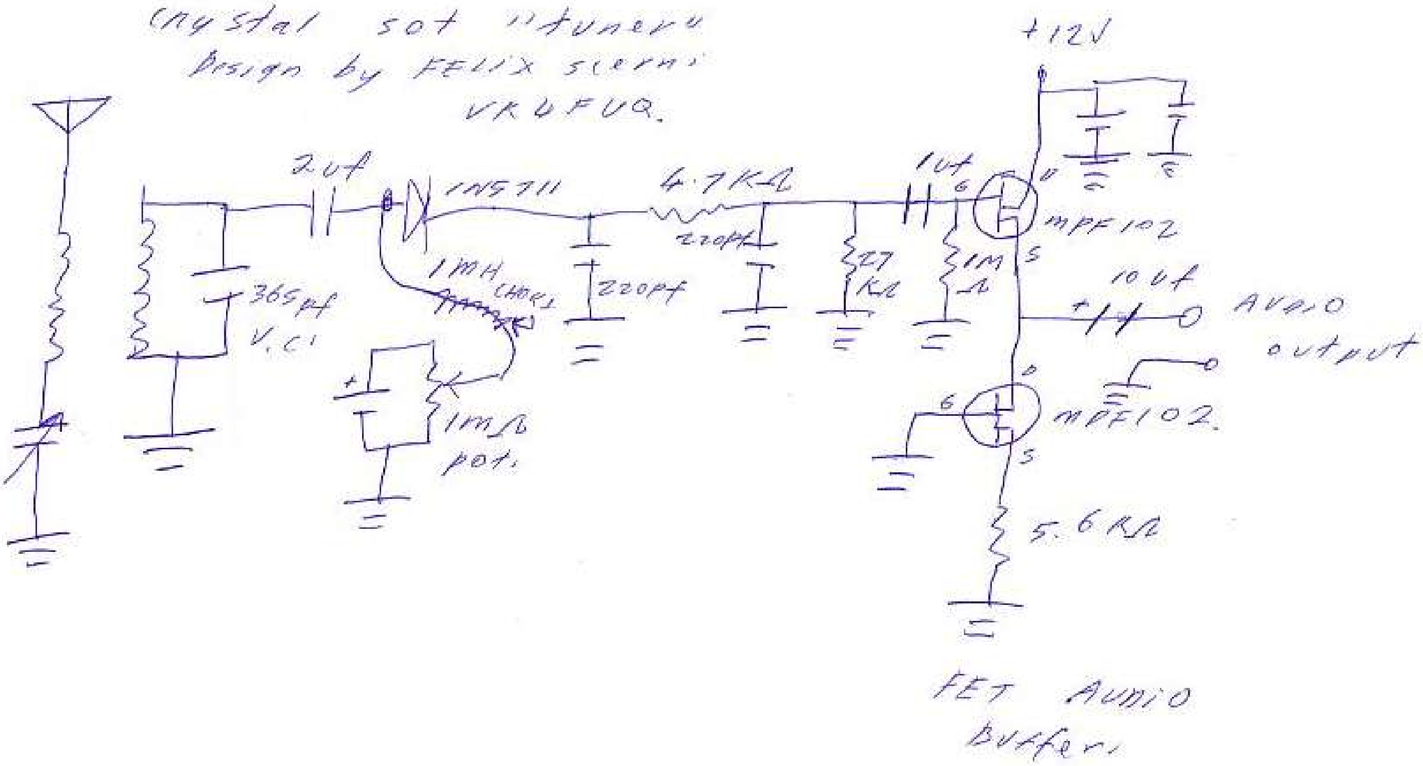
I guess we are cheating a little, because the technique is to use a little voltage bias supplied via a 1.5v battery, through a simple potentiometer voltage divider arrangement, with capacitor (for DC isolation) fed into the diode from the tuned circuit. With applied adjustable bias, I find the 1N5711 diodes absolutely superlative detectors under ANY signal strength conditions. I find the detection quality also superlative, with a clarity and low noise profile unmatched by any other diode arrangement. In my opinion, hot carrier diodes, running bias,are the best detectors overall.

Regarding other detector arrangements, the diode "voltage doubler" is often recommended, however my own experiments with the doubler arrangement have been inconclusive and slightly disappointing overall. I have found no real advantage in their use over a simple (one) diode detector, believe it or not.

Yes, they do work, but they're nothing special, at least in my opinion.

Any comments on this general subject of crystal set optimisation would be welcome.

73's Felix Scerri VK4FUQ.
22nd July 2002



Above: CRYSTAL SET BASED CIRCUIT PROVIDING A HIGH QUALITY PROGRAMME SOURCE

IMPROVED VERSION OF THE ABOVE CONCEPT !! New update from Felix Scerri February 2010:

New 'two FET infinite impedance AM detector'

I've developed a new version of my old favourite FET 'infinite impedance' AM detector that I think sounds very nice. I include a short audio of one of our local AM stations. I picked this station as it is my reference 'torture test AM station' as they run very heavy 'processing' which normally sounds yuck with all my other (diode and non diode) detectors! However it's quite clean with this detector. What do you reckon? I'll do up a circuit if you'd like to feature it in your TRF radio section. A general draft article follows.

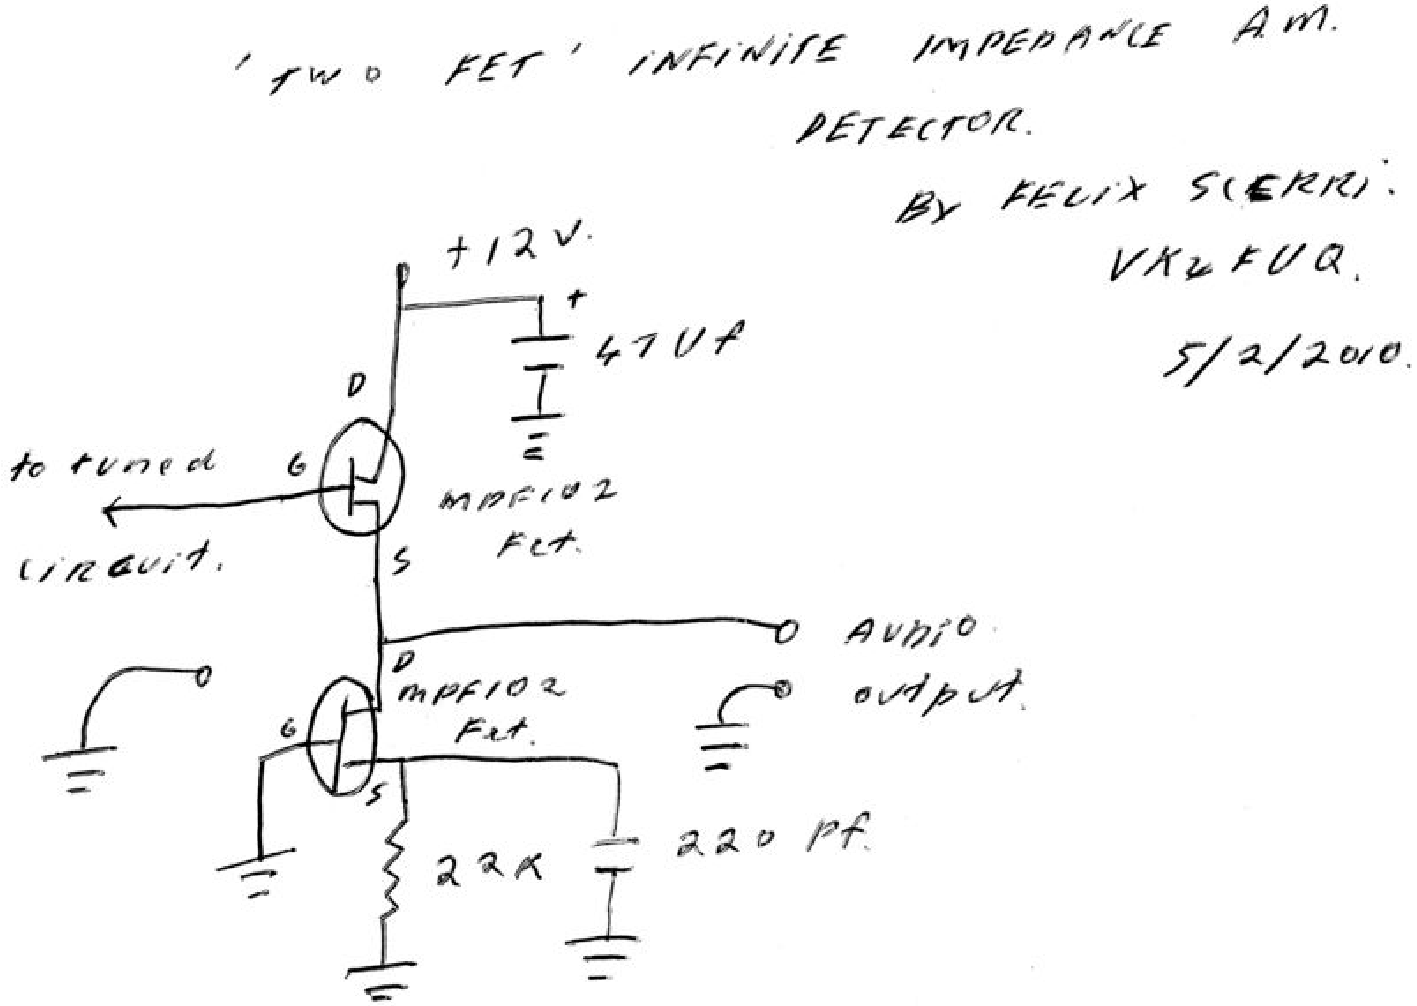
'A favourite non diode based AM detector that I've built and used many times over the years is the FET based infinite impedance detector, offering very good general AM detector performance, especially under weak RF signal conditions where diode based detectors do not perform well, especially in terms of audio distortion.

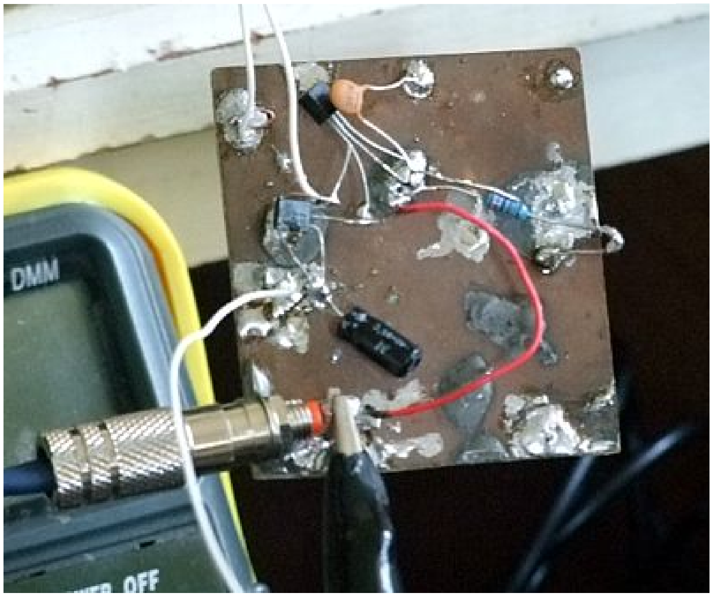
However one of the slightly strange things I've noticed about the simple FET based infinite impedance detector is the variable audio quality noted, even when using the same type of FET. Some I've built have sounded good and others slightly fuzzy when used with an audio preamp and fed into a high quality audio system. I've been giving this a considerable bit of thought of late and I've wondered if the audio distortion might be a result not necessarily of the detection process itself, but the FET stage in its guise as a 'source follower' audio stage which essentially, it is.

I have long been aware that as a simple audio buffer stage, the FET based 'source follower' can exhibit a considerable amount of audio distortion, and a technique I've long used to greatly reduce this audio distortion is to use a second FET in the source lead of the first FET as a 'constant current source' which serves to 'linearise' and greatly reduce audio distortion in the buffer stage overall. So, to test the theory I built a simple one FET infinite impedance AM detector which worked well, but with just a hint of audio 'fuzziness' on received AM stations. So I added a second FET in the source lead of the first FET wired as a constant current source, taking the output from the source of the first RF detector FET and the source resistor and RF bypass capacitor off the source lead of the second FET 'constant current source'. The result, totally clean audio! The theory seems proved! I call this modified detector the 'Two FET infinite impedance detector'

))) Here's what is sounds like - click to play the audio file (((

Here is the circuit diagram:





This detector has been a real eye opener for me in terms of its excellent performance, especially considering its circuit simplicity. Indeed in the past I have designed other more complex FET based infinite impedance circuits that do not quite work as well in practical terms as this latest circuit, at least according to my well calibrated ears!

I do not have access to any precise test equipment but my well calibrated ears tell me this 'two FET infinite impedance detector' is a beauty, surpassing practically every other AM detector I've built even at low RF input, and that's rather a impressive claim and the audio quality when used as an AM tuner feeding a high quality audio system is quite remarkable. Possibly the best thing about this detector is its excellent performance under weak signal conditions. Diode based detectors also work beautifully, but the use of an RF stage to ensure detection over a linear portion of the diode's curve is mandatory! This compound infinite impedance detector works beautifully on the sniff of a useable RF signal.

Just add a high Q tuned circuit and that's it!

Felix Scerri
VK4FUQ

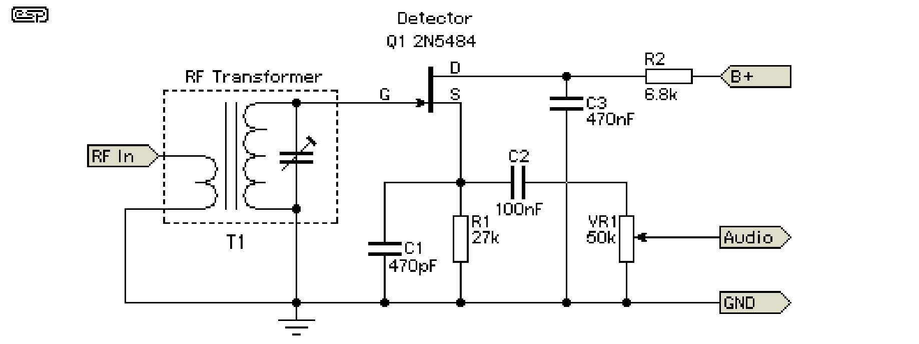
A better FET for the 'basic' Infinite Impedance Detector:

Quite recently by accident, I've realised the MPF102 FET that I've long used in my FET based infinite impedance detectors is possibly not the best FET to use. This was the reason why I developed the 'two FET' infinite impedance detector some time ago which works very well.

However I've found the choice of a more suitable FET works beautifully in the basic FET based infinite impedance detector circuit, which has appeared for many years in many editions of the ARRL Handbook.

I use the 2N5457 and others of the same 'family' may be equally suitable, but I haven't tried them! However with a 2N5457 in place of an MPF102, the basic infinite impedance detector has became my AM detector of choice. It works beautifully even at low signal input with lovely and clean low distortion audio along with a very high input impedance for good tuning selectivity. It's a beauty! The basic generic circuit is attached, courtesy of Rod Elliott's ESP website.

73 Felix VK4FUQ
10 / 02 / 2012.



The basic generic circuit is attached, courtesy of Rod Elliott's ESP website
Felix Scerri VK4FUQ

As often happens with me, my renewed interest in FET based 'infinite impedance detectors' of late has led to some interesting new research and I may have considerably improved the 'two FET infinite impedance detector' as a result.

My research suggests that although the use of a CCS (constant current source) reduces audio distortion in an audio stage, the value of the 'source resistor' in the CCS stage is somewhat critical for best results.

By using a potentiometer in lieu of a fixed resistor I have found that a resistance value of around 470 kohms cleaned up all overall audio distortion. I used an MPF102 as the CCS in this circuit. An interesting and worthwhile little circuit refinement.

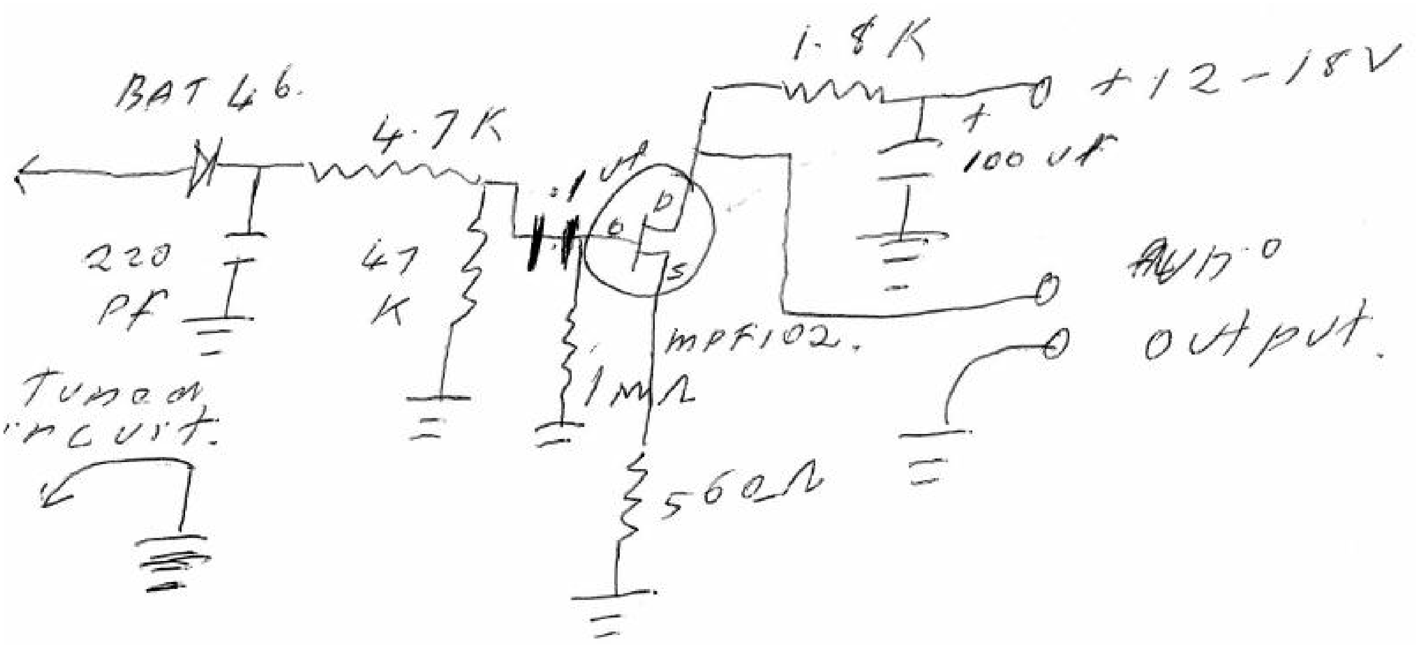
73 Felix VK4FUQ
21 / 02 / 2012.

A Minimum Component Count High Quality AM Detector

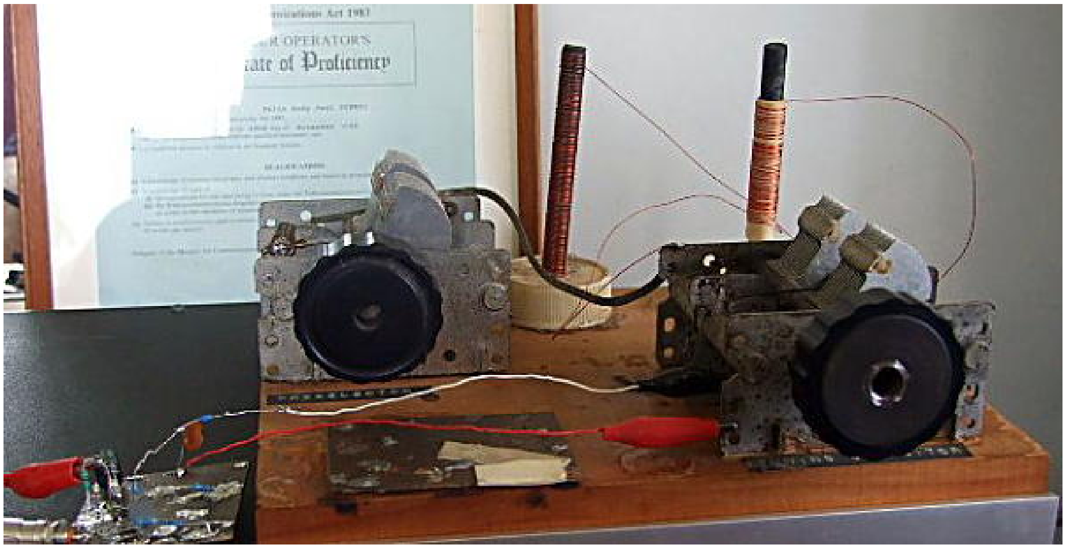
I was generally messing around with various circuit ideas and I came up with this AM detector circuit, a simple diode detector along with a FET stage. It was an attempt to provide good performance along with minimum number of components. Actually I've been pleasantly surprised at the excellent level of general performance and the best of all, it sounds great!

The circuit is quite conventional being a BAT 46 diode detector feeding an MPF102 FET buffer/ common source amplifier stage. I would ordinarily use a FET source buffer stage in this application, but opted to use a simple low gain FET 'common source' amplifier stage instead, with excellent results. I also used a BAT 46 Schottky diode instead of an ordinary germanium signal diode.

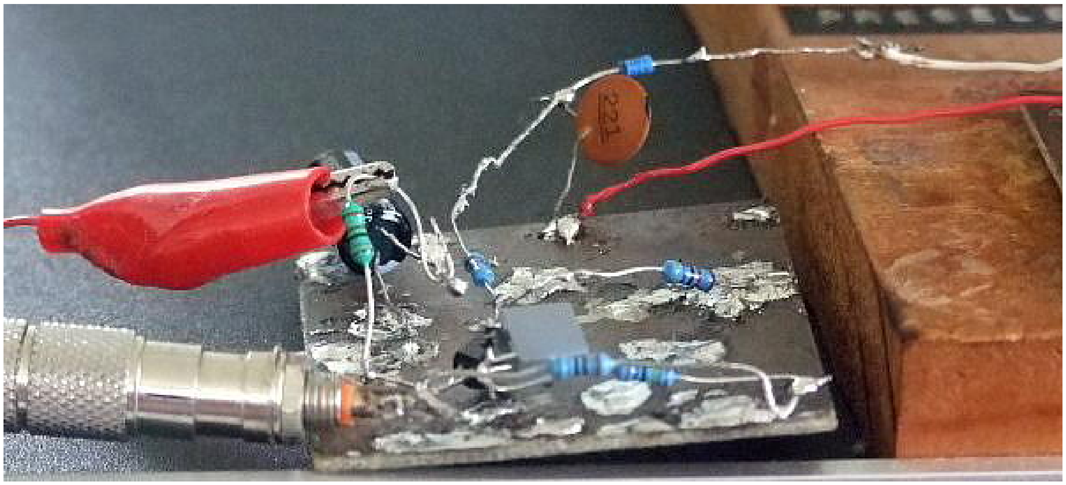
This was done for several reasons. Firstly, germanium diodes are now very hard to find but in any case these 'germanium diode equivalent' Schottky diodes are actually a superior diode, having very low noise, almost zero back leakage and an essentially complete absence of carrier storage effects and very good weak signal sensitivity. I call these diodes high fidelity diodes as they sound wonderful as RF detectors.



Circuit Diagram of the Minimum Component Count AM Detector by Felix Scerri



Minimum Component Count AM Detector by Felix Scerri



A Closer View

The high impedance of the FET's gate circuit is perfect for optimal buffering of the diode detector, something very important for good low distortion diode detector performance. Apart from providing slight voltage gain, the use of the common source FET amplifier is a new idea, as this prevents the possibility of incidental RF rectification occurring in a FET source follower stage, which can happen. A 1 uf plastic film capacitor may be added in series with the audio 'hot' output lead to block the DC offset out of the FET drain, if required.

Despite no additional RF stage ahead of the diode, audio quality on even relatively weak RF strength stations is actually very good, and of course the audio quality will be even better with increasing RF signal strength, something which will also increase the audio output level. Just on this, for a long time I was somewhat negative regarding diode detectors, as one AM station locally (the strongest one) was always distorted when using a diode detector.

I strongly suspected a transmitter fault, but my complaints were ignored, until one day some time ago when all audio distortion suddenly disappeared! Nothing was ever 'said', but I realised that my suspicions of a long standing transmitter fault were correct, after all!

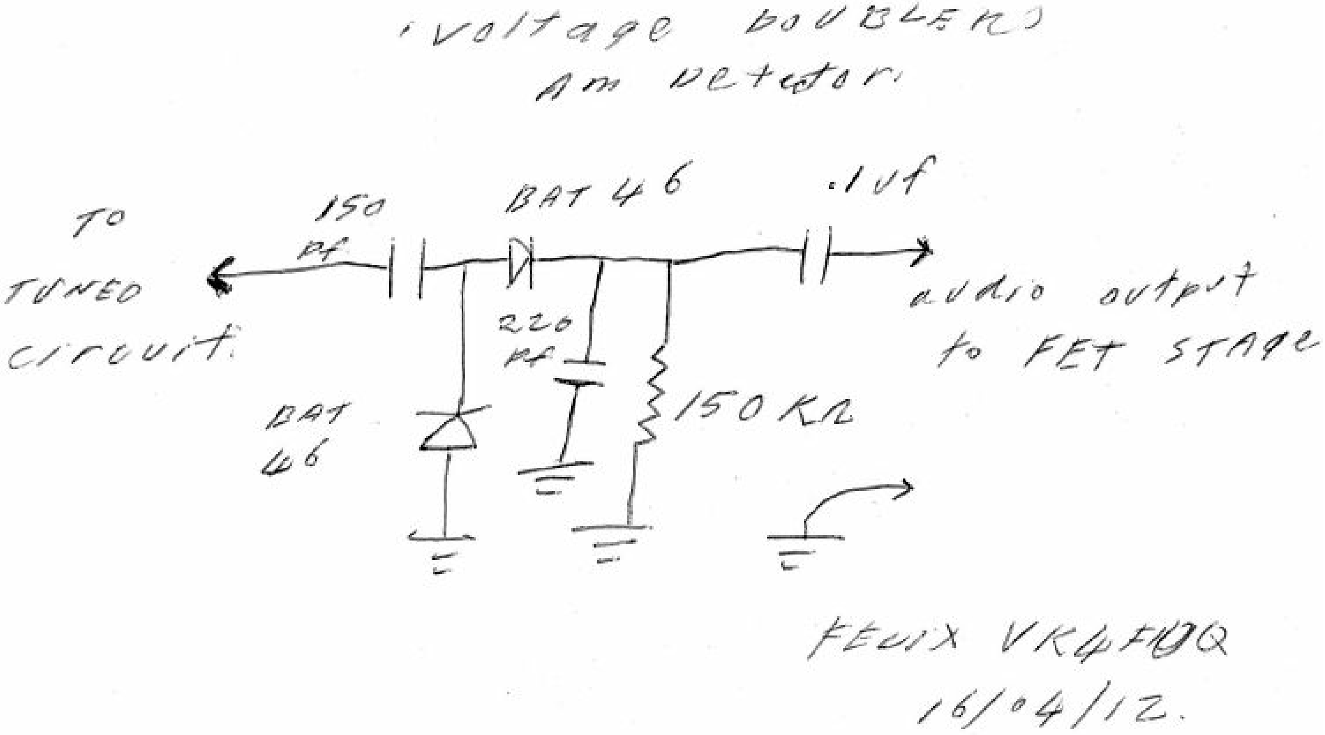
Voltage Doubler Detector

This is an AM detector circuit that I've long known about and which worked ok, but never seemed to work as well as it should have. However I spent some time late last night trying to optimise the circuit, with some success.

It is a curious circuit being essentially a 'voltage doubler' originally developed for power supply applications, and its use as an AM detector is hard to analyse! It seems that the component values in the circuit are somewhat critical for good performance and if not, the performance is rather 'ordinary'. The circuit that I eventually came up with uses a 150 picofarad 'input capacitor' with a 150 kohm 'load' resistor and loaded into a FET common source voltage amplifier stage (as previously described) through a coupling capacitor with a 1 Mohm input resistance.



With these circuit values, it all works 'quite well'. Give it a go! It's an interesting AM detector with quite good 'sensitivity' and clean audio quality, and it seems to work well at low signal levels.

Simple AM detectors: What works best? A practical experimenters viewpoint.

I have written a lot about simple AM detectors for use as tuners for feeding into an audio amplifier, and it has been a long time interest. These days I use either diode based or 'infinite impedance' types of AM detectors. In this location our 'local' AM stations are quite distant and are therefore quite weak in terms of signal strength.

As such I find infinite impedance detectors based on field effect transistors give consistently better results for tuner applications due to their lower apparent overall detector distortion. Diode based detectors are quite 'fussy' as they require both optimal output buffering (AC/DC ratio) and an 'adequate' (beyond the diode knee) level of RF signal injection. http://www.tonnesoftware.com/appnotes/demodulator/diodedemod.html

Diode based detectors will happily 'detect' at very low signal levels, however the (inevitable) audio distortion that results, can be extremely irritating to the ear! Under these conditions I find infinite impedance detectors (even without additional RF preamplification and subject to individual FET characteristics), generally sound 'cleaner' and more pleasant to the ear.

FET's of course require a power source for operation whereas diodes are passive (un-powered) detectors (most of the time), however this is of no real advantage in a tuner application as an 'active' audio amplifier stage will generally be required anyway for audio level boosting, buffering etc.

In the end it will come down to a consideration of prevailing RF signal levels and other related circuit considerations at one's location. If local RF levels are strong, a well designed diode detector will give excellent results. If not, an 'infinite impedance' type of detector is most likely the better option unless one goes towards the option of additional RF preamplification prior to the diode detector.

ANOTHER DETECTOR by Felix Scerri !

I've tried diode based 'voltage doubler' (or more correctly 'diode integrator') AM detectors before with indifferent results, however the other day, just trying a few ideas I came up with this version that works rather well, with low audio distortion, high audio output and really 'nice' audio quality and the best of all, it seems to work very at very low RF input level.

The two diode 'voltage doubler' detector using two BAT 46 silicon schottky diodes feed directly into a MPF102 source follower stage set at 1 Megohm input resistance. The 'input' capacitor feeding the diodes from a tuned circuit is 68 picofarads.

I have the simple RF filter right on the output of the FET stage. In that respect this circuit is vaguely similar to the old 'Selstead-Smith' valve AM detector of the past. An interesting one! I am very happy with its general performance. Regards, Felix vk4fuq 11/04/2013

UPDATE - JUNE 2013

G’day all, readers may recall the two FET infinite impedance detector I developed some time ago. That circuit worked well, but some samples of the MPF102 regretfully produced distorted output. However a recent discovery has resulted in an improved version that has truly exemplary performance.

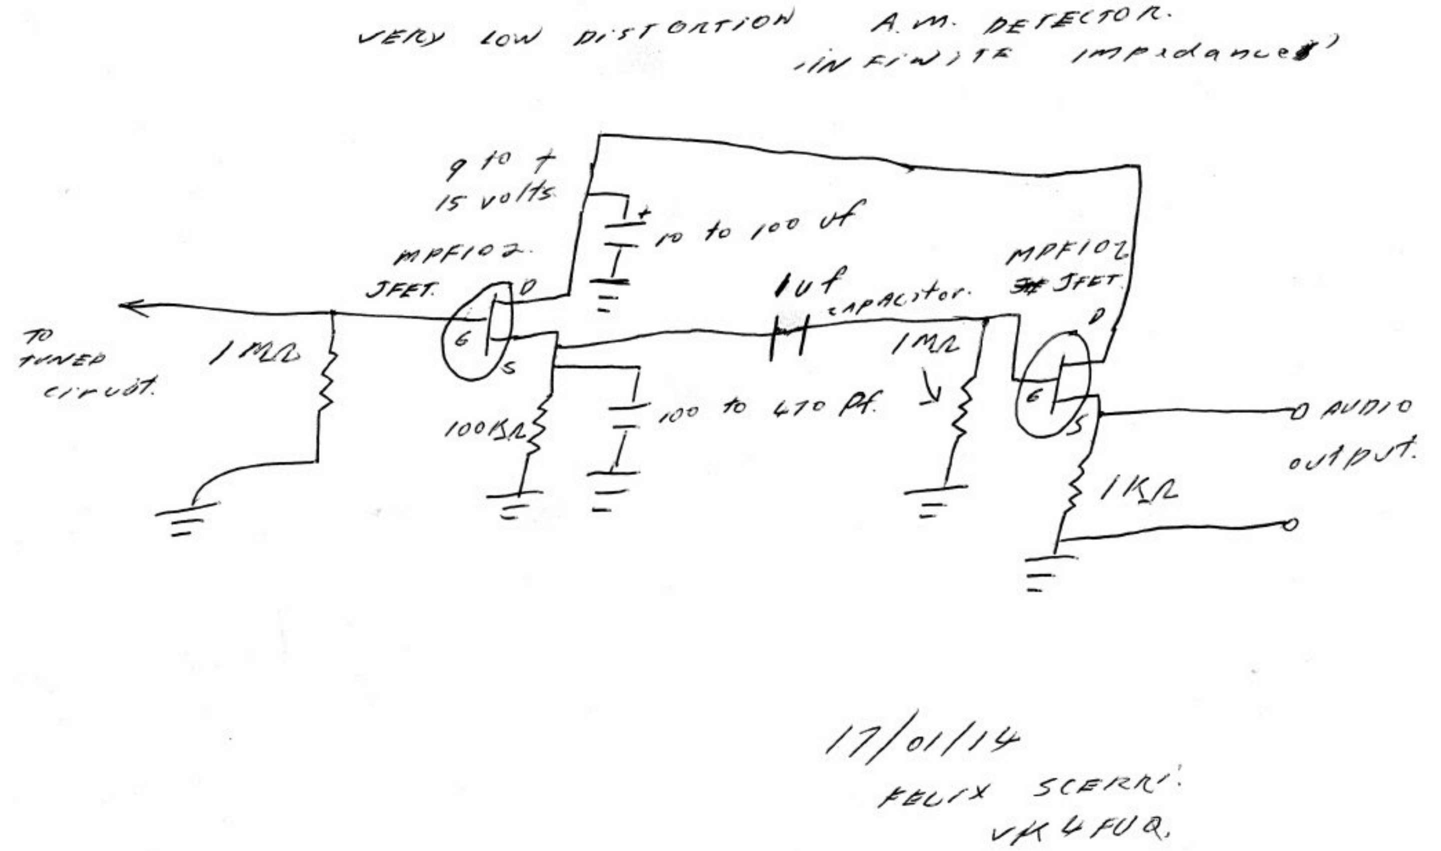
The MPF102 is in all honesty a device essentially designed for VHF applications, but is often used in simple audio applications albeit with occasionally indifferent results, due to general device parameter ‘spread’. More or less by empirical trial and error I have found that a simple change in source resistor value to 100 k (from a much lower value), pretty well fixes everything.

In a FET source follower circuit this is interesting as the output impedance is actually a lot lower than 100 k due to the action of the FET’s transconductance. It is similar to the action of a bipolar transistor emitter follower circuit. In fact a simple infinite impedance detector with a 100 k source resistor actually works very well and will be good enough for many applications, however the addition of a second FET as a constant current source does markedly reduce overall audio distortion in the stage overall, and produces very clean and low distortion audio quality and also reduces the output impedance considerably (good for tuner applications), so take your pick!

Regards, Felix vk4fuq 02/06/2013.

UPDATE - JANUARY 2014

A simple modification to the basic FET 'infinite impedance' AM detector that dramatically improves performance.



G’day all, over the Christmas break just messing around I worked out (mostly by accident), a simple modification for the simple FET based ‘infinite impedance’ detector circuit that dramatically improves weak signal performance and also greatly reduces audio distortion.

Essentially by the addition of another FET ‘buffer’ stage, another source follower, capacitively coupled from the first detector stage. The circuit is actually a simplified version of the circuit that I described in this link, http://sound.westhost.com/articles/am-radio.htm (figure 6) and testing the two head to head, they both sound superb and the simpler version is actually somewhat easier to build. I cannot get over how low distortion and ‘nice’ the recovered audio sounds. It is a joy to listen to!

Regards, Felix vk4fuq 12/01/2014.

Diodes for ‘weak signal’ crystal set applications.

As I am primarily interested in using crystal sets as AM tuners for feeding into a preamplifier/amplifier and loudspeakers, the actual type of diode can be relatively critical. In a strong signal area, not so much, but in a weak signal area such as where I reside, definitely. A diode with a good ‘square law’ performance (the area below the ‘knee’ in the diode curve), generally results in much cleaner and lower distortion than other good performing diodes, and believe me diode distortion under weak conditions, even with optimised diode ‘buffering’ used is very nasty sounding to the ear!

Testing many, many diodes in actual working crystal sets and listening critically to the audio output, it seems to me that the best diodes to use under weak signal conditions are the so called ‘gold bonded’ germanium diodes. I have sampled many different gold bonded germanium diodes and they all work well in this specific application, although sometimes the rectified output voltage may not be as high as other germanium or silicon schottky diodes, however the audio quality is much cleaner and shows much less apparent distortion!

I have tried OA5, OA47, IN141 and several ‘CG’ gold bonded germanium diodes with consistently excellent results. Other ‘ordinary’ germanium diodes may also work well under weak signal conditions, but they will need to be tested individually to check actual performance in a working circuit. One thing that I have noticed about germanium diodes is that due the ‘point contact’ nature of their construction, even diodes of the same specific type can exhibit rather different levels of performance!

The otherwise very good BAT46 silicon schottky diode works extremely well at good RF input level but not so well at weak RF input, especially when heavy broadcast ‘processing’ (commonplace these days), is used. New ‘gold bonded’ germanium diodes are probably no longer made although I am aware that they can be purchased through vendors over the internet. Apart from that, they may be found in old gear. As stated earlier, ordinary germanium diodes may be quite good but will need to be checked individually. Diodes are complex things!

Felix (vk4fuq). 29/01/2014.

* * * * * * * * * * * * * *

Just when I thought that I’ve tried everything I realised that I’ve not tried a voltage doubler (diode integrator) detector with an RF stage in front. It is an unfortunate fact that all diode detectors ‘need’ a good RF injection level (and buffering) or audio distortion becomes ‘bad’ (an understatement!)

Consider yourself very lucky if you live in a strong signal area! (unfortunately I don’t). Anyway I quickly built a couple of prototypes which worked ok but not as well as hoped. Initially I tried using a source follower buffer (no voltage gain), but converting it to a common source amplifier (with appreciable voltage gain), seemed no better, which was strange.

After staring at my prototype for what seemed like forever with my magnifiers on, I (finally) realised my mistake. A common source stage takes its output off the ‘drain’ terminal of the FET, not the ‘source’ terminal as it does with the FET source follower buffer stage. I shifted one wire, and all worked as expected and it sounds fantastic! All diode detectors (one diode envelope detectors, doubler detectors etc), need good RF input and a simple untuned FET RF gain stage works very well. As to the sound, it sounds great.

Felix Scerri's FET Crystal Set with Voltage Doubler

A 'nice sounding' AM detector - update October 2015

Looking through these pages the other day I was slightly shocked to realize that I’ve completely forgotten about some of the circuits that I’ve contributed in earlier days! They all work pretty well, however in my advancing older age and a little like my tastes in high fidelity generally, I’m starting to show a particular preference for ‘nice sounding’ bits of audio gear.

I guess that this also means low noise/low distortion too, although with AM broadcasting, at least in this country and probably elsewhere in the world too, the very common use of broadcasting ‘processing’ tends to make it hard for AM detectors generally, often resulting in a ‘hard/compressed’ sort of sound although still low in distortion, is not ‘nice sounding’, if that makes any sense!

Well of all the AM detectors that I’ve tried and/or developed, only one sounds ‘nice’ when confronted by heavy broadcast processing and that is an AM detector ‘based’ on a voltage doubler/diode integrator circuit (similar to the above circuit, actually the 68 pf capacitor should be changed to .1 uf, for slightly greater output).

It has taken me a very long time (years) to ‘optimise’ this circuit, but as it presently stands this is my favourite ‘nice sounding’ AM detector, and gets most use for general high quality listening on the AM broadcast band. It sounds really good! It somewhat reminds me of an old OA47 gold bonded diode detector from years ago before such abhorrent ‘processing’ became commonplace!

Ah yes the OA47….now that is a lovely sounding detector diode!

Regards, Felix vk4fuq. 17 / 10 / 2015.

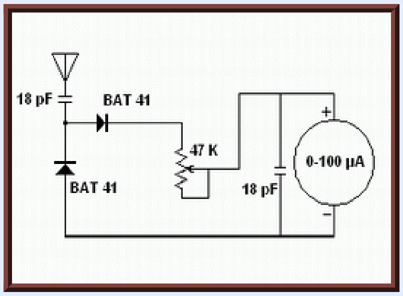
RF field strength meter version 1.

I made a RF simple field strength meter for test the remote control from doors ,alarm e.t.c at frequency VHF-UHF, i used one μA meter ,2 diodes ,2 ceramic capacitors,a potentiometer,a box ,and one telescopic antenna.When press the button at remote control,output there is small current RF,where with this simple circuit ,easy i can to know if remote controls it work or no.

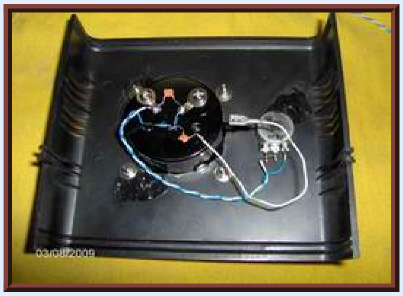
Here it is the electronic design



Here it is the electronic material,without yet the potentiometer 47 Kohm, 2 capacitor 18 pF,2 diodes BAT 41,and a μA meter

Here it is the plastic box,i have open holes for μA meter ,and i have touch the telescopic antenna

Here with soldering iron the components it is ready



Here it is the sensitivity test

Here it the test with remote temperature /humidity sensor

It is ready

Ready with full open telescopic antenna

"Picks Power from the Air"

by
Charlton Lawrence Edholm

A remarkable scene took place in the legislature of Arizona this spring when the lawmakers enthusiastically voted for the parole of a certain convict in the State penitentiary, granting him a leave of absence for 30 days and by means of private contributions raising a fund to defray his expenses to Washington DC and return.

The prisoner, Roy J. Meyers, is serving a 3-1/2 year sentence, but in spite of the fact that he bears the stigma of a convicted lawbreaker, he has demonstrated that a convict can be a useful member of society. During his imprisonment he perfected an electrical device of such original character as to arouse feelings of wonder and skepticism until experts had seen it in actual operation. It is a device to draw electricity from the atmosphere for light and power, and the 30-day parole was granted in order that the inventor might protect his rights through the patent office at Washington.

With the acquiescence of the legislature, Governor Hunt granted the parole and the prisoner was allowed to go free without any guard or any assurance but his word of honor that he would return. Two days before the period had elapsed, Meyer again presented himself before the governor, having accomplished his mission, and then returned to the penitentiary at Florence, where he continues to serve his sentence.

This, in brief, is the picturesque story which has called attention of the civilized world to a newly discovered electrical genius, and to another feature of the case which is of equal importance and human interest; namely, the enlightened policy pursued by our youngest State in its treatment of convicts...

Before entering the prison, Meyer had already applied for various patents, among them one for an improved trolley wheel head which prevents the trolley wheel from jumping the wire. Meyers had a conference with Superintendent Sims and Parole Clerk Sanders, and it was to these gentlemen that the inventor first explained the principles of his new device for securing electrical energy from the air. The officials were willing to give the man the opportunity to develop his plan and a little wooden building outside the walls was turned over to Meyers and was fitted up as a workshop and a laboratory. The first demonstration of the new apparatus was made shortly thereafter, the electricity drawn from the atmosphere being used to spark the gas engines of the pump house, and although the device was crude yet it did the work, and removed the doubts of his friends. Furtter development of the "absorber" followed, and his second model was constructed, and developed 8 volts. The machine came to the attention of the remarkable woman who brought his name before the legislature.

This was Miss Kate Barnard, State Commissioner of Charities and Corrections of Oklahoma, who was a guest of Mr. Sims, while studying prison conditions. She saw the machine at work, became familiar with the facts of Meyers' case, and was impressed by his rather blunt and unaffected personality, for Meyers has nothing of the polish or glibness of the poseur. He is a simple, earnest student of mechanical problems and not the sort of man to make a sentimental appeal for sympathy because of any grace of person or manner. Therefore it was the value of Meyers' invention, together with his essential integrity (in spite of his lapse) which so strongly impressed Miss Barnard that when she appeared before the Arizona legislature not long afterwards, addressing that body on the need of enlightened legislature along the line of her own work, she told the story of Roy Meyers and his epoch-making invention.

So, early in May, Meyers set out for Washington, unaccompanied.

In his own words: "When I arrived in Washington and laid my plans before the patent office experts, they merely smiled and told me that I would have to build a model and demonstrate my claims --- that it seemed strange that I, unknown as I am in the electrical world, should have accomplished the things for which Edison, Tesla and other experts have been striving for years.

"They could grasp the meaning of my drawings nor the explanation I tried to make to them. There was little time to spare, as I had only 20 days left of my leave, but I set to work in a few days was able to take a crude model around to the patent office to make a demonstration.

"Arriving at the patent office I telephoned to a friend who had been so kind as to introduce me and aid me in reaching the proper officials. The absorber was hoisted on two short poles and made to work. While they were as yet unable to understand the principles involved and hardly willing to believe their eyes, they were forced to admit that I had something new and different, and they told me that there would be no further objection; that I might file my application without further delay.

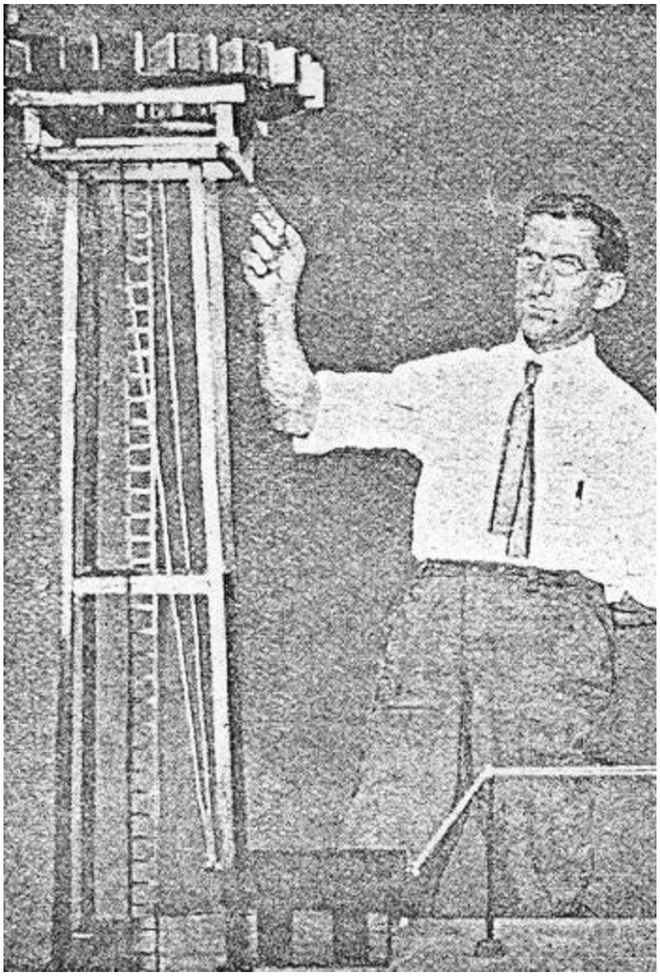
"I hope to construct my first large machine right here in Phoenix. I feel grateful; to Governor Hunt and others for what they have done for me and to the help they have given in securing protection I might not otherwise have had, and I am desirous of demonstrating this gratitude. I am going back to Florence today to resume the serving of my sentence, which will expire in 10 months. Then, here in Phoenix, I will begin the work of making my machines."

While there are some details of the device which the inventor refuses to make public, yet there are many general features that may be explained. It is planned that the machine, to be set up in Phoenix, will generate sufficient power to light the city, and will consist of a 200 foot tower upon which is placed the "absorber". The latter consists of a series of magnetized steel plates set in a circle (the manner of preparing them is kept secret) and this mechanism attracts the electricity from the atmosphere. This is carried by wires to a transformer in the engine house below and thence is applied to produce either power or light after the usual manner.

In an authorized statement Meyers says: "The flow of electricity is constant. When it emerges into the transformer it is in the form of a direct current. It will absorb the electricity day and night and will work whenever the wireless will work. I can put up a plant to supply such a building as the Adams Hotel for about $1500, and one of the principal items of the expense is the cost of the towers, the wires, the magnetizing of one set of plates, which is part of the secret of the treatment which makes it respond to the accumulations of the atmosphere.

"For use in the case of an electrical storm I have made what I call a modified form of circuit breaker, such as is commonly used as a lightning arrester on telegraph lines. In case of a storm the accumulator would suddenly become overcharged, possibly, and as the electricity would not of itself flow back into the air, the result might be disastrous. So I send it down into the ground, whenever the voltage rises above a certain amount."

Roy J. Meyers & the "Absorber"



Modern Electronics **(1914 ?)**

Electricity From Air New Great Discovery

by

Dr Leonard Keene Hirshberg

Working quietly in the heart of Baltimore for weeks on an invention which some critics say will revolutionize the method of converting electricity to practical use has been Roy J. Meyers, who like Benjamin Franklin, extracts the electric current from the air.

Mr Meyers invention was made last summer while he was confined in the penitentiary at Florence, Arizona. His first finished apparatus was made in Baltimore.

A practical, unlettered electrician, Mr Meyers, while in Arizona, was arrested on a comparatively minor charge and sent to the penitentiary. There he was placed in charge of the prison electrical plant, and there he says he made his discovery that the current which the civilized world is beginning to use most extensively for light and power could be transformed from the atmosphere without the aid of moving machines or batteries.

Miss Kate Barnard, Commissioner of Charities and Corrections, of Oklahoma, hearing of Meyers' invention and of his desire to have it patented, appeared before the Arizona Legislature to make an appeal in behalf of the young convict. As a result a special bill was passed which granted Meyers a month's leave of absence on parole. He went unaccompanied to Washington, filed his patent applications and returned to the penitentiary. Since then he has been indefinitely paroled.

He came to Baltimore as the place where he could easily obtain the mechanical parts needed to make a more nearly perfect machine than the crude model he has fashioned in the penitentiary workshop, and is making his headquarters here while working on his invention. With him is W.E. Chenot, who has been his assistant in assembling and testing the machine and who says that he has bought Meyers' patent rights for Germany.

They have proved beyond doubt that the invention is practical and that when finally brought to a state of perfection it will introduce a new epoch in the industrial use of electricity. By Westinghouse meters they tested the strength of the current gathered from the air, and with the use of only two of the four rectifying transformers the voltmeter recorded four and one-half volts, and the ammeter, which had the capacity of recording 75 amperes, was broken by the force of the current.

The machine itself is simple. It is in reality a transformer, which is familiar to anyone knowing anything at all about electricity in its practical uses. On a high tripod, which resembles somewhat the framework of a windmill tower, is the transformer, which Mr Meyers calls his 'absorber'. It is made up of an iron core, wrapped with copper wire. The secret of the invention is the manner in which the disks composing this 'absorber' are magnetized, and this secret Meyers says he found by accident while at work in prison.

What the machine, when finally perfected, will do is yet to be seen. Its inventor claims that it will greatly reduce the cost of making electricity. No batteries of any kind are needed, he says, and not a part of the machine turns upon the other. It is as durable, apparently, as an electric light pole. One of these machines, says Meyers, when perfected may be placed on a vehicle and transform enough electricity to give motive power, be that vehicle a locomotive or an automobile. He declared it can be placed on a building to furnish electric lights or power, and that the only wear will be upon the machinery which its current runs.

Meyers is 34 years old and he gained his knowledge of electricity by working in shops along the Pacific Coast. The depths of the mysteries of electricity he has not explored, but he is certain that he has found the means of absorbing it from the air and of converting it to the use of mankind.

British (GB) Patent # 191301098

Improvements in and Relating to Apparatus for Producing Electricity.

1-14-1914

Roy Jerome Meyers

Classification: - international: H05F7/00; H05F7/00; - european: H05F7/00
Application number: GBD191301098 19130114
Priority number(s): GBT191301098 19130114

Abstract ~ Vapour apparatus, arrangements of. - A rectifier for use with apparatus for producing electricity from the earth consists of mercury- vapour lamps constructed and arranged as shown in Fig. 4. Each lamp comprises two wires 6<1>, 7<1> wound around a steel tube 15 surrounding a

mercury tube 11 preferably of copper. The coil 6<1> is connected between the electrode 14 and the terminal 18, and the coil 7<1> between the terminals 19, 5. The coils 6<1>, 7<1> are preferably composed of soft iron. Reference has been directed by the Comp- troller to Specifications 16,709/87, 14,033/99, and 5457/11, [all in Class 53, Galvanic batteries], and 15,412/06.

British Patent # 1098

(January 14, 1913)

Improvements in and Relating to Apparatus for Producing Electricity

Roy Jerome Meyers

This invention relates to improvements in apparatus for the production of electrical currents, and the primary object in view is the production of a commercially serviceable electrical current without the employment of mechanical or chemical action. To this end the invention comprises means for producing what I believe to be dynamic electricity from the earth and its ambient elements.

I am, of course aware that it has been proposed to obtain static charges from upper strata of the atmosphere, but such charges are recognized as of widely variant potential and have thus far proved of no practical commercial value, and the present invention is distinguished from all such apparatus as has heretofore been employed for attracting static charges by the fact that this improved apparatus is not designed or employed to produce or generate irregular, fluctuating or other electrical charges which lack constancy, but on the other hand I have by actual test been able to produce from a very small apparatus at comparatively low elevation, say about 50 or 60 feet above the earth's surface, a substantially constant current at a commercially usable voltage and amperage. This current I ascertained by repeated tests is capable of being readily increased by additions of the unit elements in the apparatus hereinafter set forth, and I am convinced from the constancy of the current obtained and its comparatively low potential that the current is dynamic and not static, although, of course, it is not impossible that certain static discharges occur and, in fact, I have found occasion to provide against the damage which might result from such discharge by the provision of lightning arresters and cut-out apparatus which assist in rendering the obtained current stable by eliminating sudden fluctuations which sometimes occur during conditions of high humidity from what I consider static discharges. The nature of my invention is obviously such that I have been unable to establish authoritatively all of the principles involved, and some of the theories herein expressed may possibly prove erroneous, but I do know and am able to demonstrate that the apparatus which I have discovered does produce, generate, or otherwise acquire a difference of potential representing a current amperage above stated, or varied therefrom at the will of the operator according to the uses which the current is to be subjected.

The invention comprises generically means for producing electrical currents of serviceable potential substantially without the employment of mechanical or chemical action, and in this connection I have been able to observe no chemical action whatever on the parts utilized although deterioration may possibly occur in some of the parts, but so far as I am able to determine such deterioration does not add to the current supply but is merely incidental to the effect of climatic action.

The invention more specifically comprises the employment of a magnet or magnets and a co-operating element, such as zinc disposed adjacent to the magnet or magnets and connected in such manner and arranged relative to the earth so as to produce current, my observation being that current is produced only when such magnets have their poles facing substantially to the north and south and the zincs are disposed substantially along the magnets.

The invention also comprehends other details of construction, combinations and arrangements of parts as will hereinafter be fully set forth and claimed.

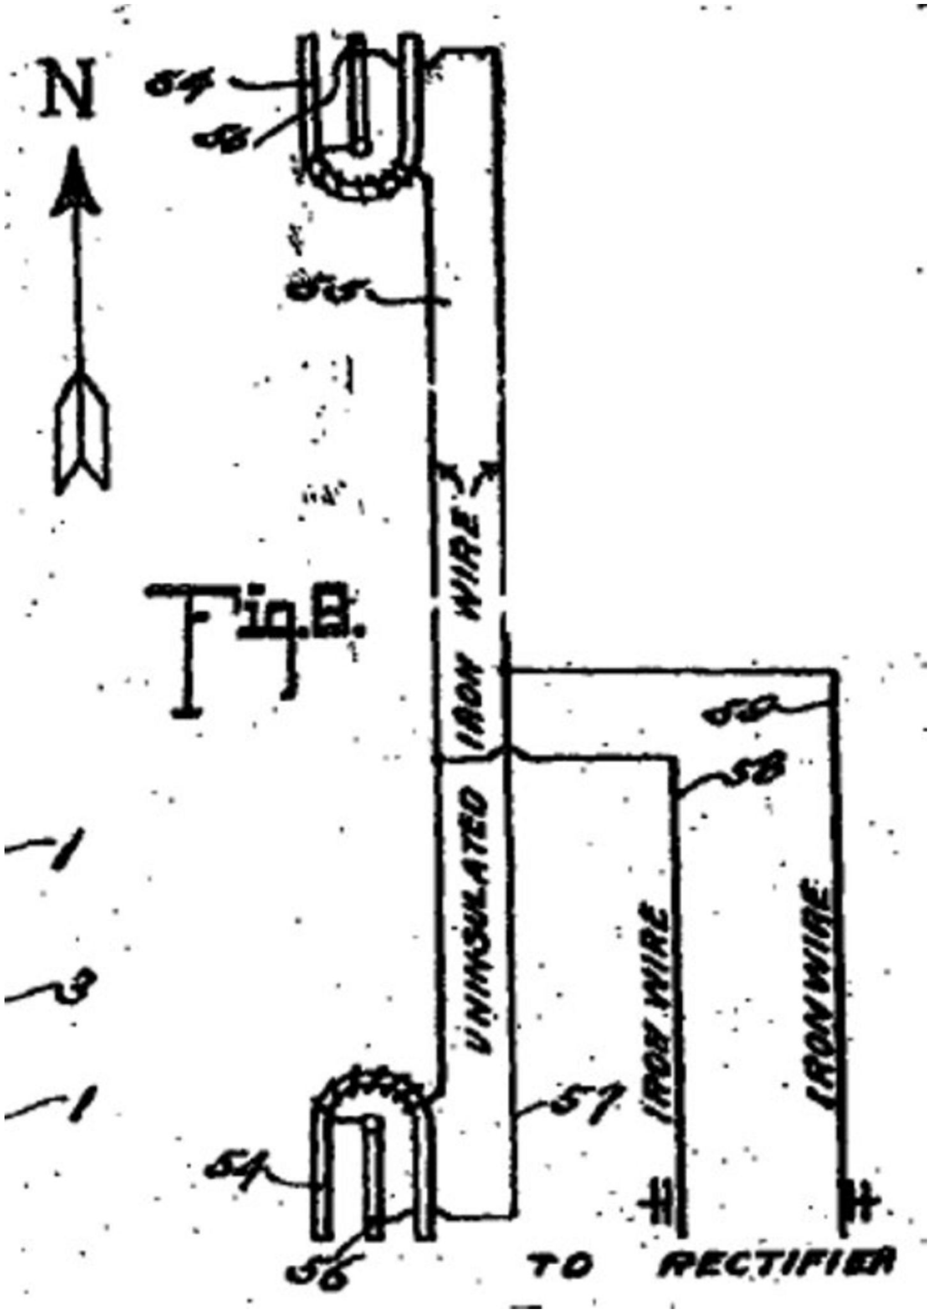

Fig. 8.

Referring to the drawing by numerals, 1,1 indicates magnets connected by a magnetic substance 2, preferably an iron wire. The magnets 1 are arranged in pairs, one pair being spaced beneath the other, and interposed between the magnets are zinc plates 3,3 connected by an iron wire conductor 4. Suitable insulating supports 5 are arranged for sustaining the respective magnets 1 and plates 3,3. Each plate 3 is preferably bent substantially into V form, as clearly seen in Figure 1, and the V1 of one of the plates opens or faces toward the north and the V of the other plate to the South. I have determined by experimentation that it is essential that the plates 3 be disposed substantially north and south with their flat faces approximately parallel to the adjacent faces of the co-operating magnets, although by experience I have not discovered any material difference in the current obtained when the plates are disposed slightly to one side of north and south, as for instance when the plates are disposed slightly to one side of north and south, as for instance when disposed in the line of the magnetic polarity of the earth. The same is true with respect to the magnets 1, the said magnets being disposed substantially north and south for operative purposes, although I find that it is immaterial whether the north pole of one of the magnets is disposed to the north and the south pole to the south, or vice versa, and it is my conviction from experience that it is essential to have the magnets of each pair connected by magnetic material so that the magnets substantially become one with a pole exposed to the north and a pole exposed to the north. In Figure 1, I have indicated in full lines by the letters 8 and N the respective polarities of the magnets 1, and have indicated in dotted lines the other pole of those magnets when the connection 2 is severed. I have found that the magnets and zinc plates operate to produce, whether by collection or generation I am not certain, electrical currents when disposed substantially north and south, but when disposed substantially east and west no such currents are produced. I also find that the question of elevation is by no means vital, but it is true that more efficient results are obtained by placing the zincs and magnets on elevated supports. I furthermore find from tests that it is possible to obtain currents from the apparatus with the zincs and magnets disposed in a building or otherwise enclosed, although more efficient results are obtained by having the said elements arranged in the open.

While in Figures 1, 2, and 3, I have shown the magnets and the zinc plates as superimposed, it will be apparent, as hereinafter fully set forth, that these elements may be juxtaposed in horizontal planes, and substantially the same results will be secured. Furthermore, the magnets 1 with the interposed zincs 3, as shown in Figures 1, 2 and 3 merely represent a unit which may be repeated either horizontally or vertically for increasing the current supply, and when the unit is repeated the zinc plates are arranged alternating with the magnets throughout the entire series as hereinafter indicated.

A conductor 6 is connected in multiple with the conductors 2 and a conductor 7 is connected with conductor 4, the conductor 6 extending to one terminal of a rectifier which I have indicated by the general reference character 8, and the conductor 7 extending to the other terminal of said rectifier. The rectifier as seen in diagram in Figure 1 may assume any of several well known embodiments of the electrical valve type and may consist of four asymmetric cells or Cooper-Hewitt mercury vapor lamps connected as indicated in Figure 1 for permitting communication of the positive impulses from the conductor 6 only to the line conductor 9 and the negative impulses from conductor 6 on only to the line conductor 10. The current from this rectifier may be delivered through the conductors 9 and 10 to any suitable source for consumption.

While the said rectifier 8 may consist of any of the known types, as above outlined, it preferably consists of a specially constructed rectifier which also has the capacity of intensifying the current and comprises specifically the elements shown in detail in Figures 4, 5, and 6 wherein I have disclosed the detail wiring of the rectifier when composed of four of the rectifying and intensify in elements instead of asymmetric cells or simple mercury vapor valves. As each of these structures is an exact embodiment of all the others, one only will be described, and the description will apply to all. The rectifying element of each construction consists of a mercury tube 11 which is preferably formed of glass or other suitable material, and comprises a cylinder having its end portions tapered and each terminating in an insulating plug or stopper 12. Through the upper stopper 12 is extended the electrode 13 which extends well into the tube and preferably substantially one-half the length thereof to a point adjacent the inner end of an opposing electrode 14 which latter electrode extends thence downwardly through the insulation 12 at the lower end of the tube. The tube 11 is supplied with mercury and is adapted to operate on the principle of the mercury vapor lamp, serving to rectify current by checking back impulses of one sign and permitting passage of impulses of the other. To avoid the necessity for utilizing a starter, as is common with the lamp type of electrical valve, the supply of mercury within the tube may be sufficient to contact with the lower end of the electrode 13 when current is not being supplied, so that as soon as current is passed from one electrode to the other sufficiently for volatilizing that portion of the mercury immediately adjacent the lower end of electrode 13, the structure begins its operation as a rectifier. The tube 11 is surrounded by a tube 15 which is preferably spaced from tube 11 sufficiently for allowing atmospheric or other cooling circulation to pass the tube 11. In some instances, it may be desirable to cool the tube 11 by a surrounding body of liquid, as hereinafter indicated. The tube 15 may be of insulating material but I find efficient results attained by the employment of a steel tube, and fixed to the ends of the of the tube are insulating disks 16, 16 forming a spool on which are wound twin wires 6^1 and 7^1, the wire 6^1 being connected at the inner helix of the coil with the outer end of the electrode 14, the lower portion of said electrode being extended to one side of the tube 11 and passed through an insulating sleeve 17 extending through the tube 15, and at its outer end merging into the adjacent end of the wire 6^1. The wire 7^1 extends directly from the outer portion of the spool through the several helices to a point adjacent the juncture of the electrode 14 with wire 6^1 and thence extends in mechanical parallelism with the wire throughout the coil, the wire 6^1 ending in a terminal 18 and the wire 7^1 ending in a terminal 19. For the sake of convenience of description and of tracing the circuits, each of the apparatus just above described and herein known as an intensifier and rectifier will be mentioned as A, B, C and D, respectively. Conductor 6 is formed with branches 20 and 21 and conductor 7 is formed with similar branches 22 and 23. Branch 20 from conductor 6 connects with conductor 7^1 of intensifier B and branch 21 of conductor 6 connects with the conductor 7^1 of intensifier C, while branch 22 of conductor 7 of intensifier C, while branch 22 of conductor 7 connects with conductor 7^1 of intensifier D. A conductor 27 is connected with terminal 19 of intensifier A and extends to and is connected with the terminal 18 of intensifier C, and a conductor 7 connects with conductor 7^1 of intensifier D. A conductor 27 is connected with terminal 19 of intensifier A. and extends to and is connected with terminal 18 of intensifier C, and a conductor 28 is connected with the terminal 19 of intensifier C and extends from the terminal 19 of intensifier B to the terminal 18 of intensifier D to electrode 13 of intensifier B. Each electrode 13 is supported on a spider 13^1 resting on the upper disk 16 of the respective intensifier. Conductors 31 and 32 are connected with the terminals 18 of intensifiers A and B and are united to form the positive line wire 9 which co-operates with the negative line wire 10 and extends to any suitable point of consumption. The line wire 10 is provided with branches 35 and 36 extending to the electrodes 13 of intensifiers C and D for completing the negative side of the circuit.

Thus it will be seen that alternating currents produced in the wires 6 and 7 will be rectified and delivered in the form of a direct current through the line wires 9 and 10, and I find by experiment that the wires 6 and 7 should be of iron, preferably soft, and may of course be insulated, the other wiring not specified as iron being of copper or other suitable material.

In carrying out the operation as stated, the circuits may be traced as follows: A positive impulse starting at the zincs 3 is directed along conductor 7 to branch 23 to conductor 7^1 and the winding of the rectifier of intensifier B through said rectifier to the conductor 6^1, through the winding thereof to the contact 18, conductor 32 and to the line wire 9. The next or negative impulse directed along conductor 7 cannot find its way along branch 23 and the circuit just above traced because it cannot pass across the rectifier of intensifier B but instead the negative impulse passes along conductor 22 to conductor 7 of intensifier A and the winding thereof to the contact 19 and to conductor 27 to contact 18 of intensifier C, to the winding of the wire 6^1 thereof to the electrode 14 through the rectifier to the of the electrode 13 and conductor of intensifier A, electrode 14 thereof and conductor 6^1 to contact 18 and wire 31 to line wire 9. Obviously the positive impulse cannot pass along the wire 20 because of its inverse approach to the rectifier of intensifier B. The next impulse or negative impulse delivered to conductor 6 cannot pass along conductor 21 because of its connection with electrode 13 of the rectifier of intensifier A, but instead passes along conductor 20 to the wire 7^1 and its winding forming part of intensifier B to the contact 19 and conductor 29 to contact 18 and the winding of wire 6^1 of intensifier D to the electrode 14 and through the rectifier to the electrode 13 and conductor 35 to line wire 10. Thus the current is rectified and all positive impulses directed along one line and all negative impulses along the other lie s that the potential difference between the two lines will be maximum for the given current of the alternating circuit. It is, of course, apparent that a less number of intensifiers with their accompanying rectifier elements may be employed with a sacrifice of the impulses which are checked back from a lack of ability to pass the respective rectifier elements, and in fact I have secured efficient results by the use of a single intensifier with its rectifier elements, as hereinafter set forth.

Grounding conductors 37 and 38 are connected respectively with the conductors 6 and 7 and are provided with the ordinary lightning arresters 39 and 40 respectively for protecting the circuit against high tension static charges.

Conductors 41 and 42 are connected respectively with the conductors 6 and 7 and each connects with an automatic cutout 43 which is grounded as at 4. Each of said automatic cutouts is exactly like the other and one of the same is shown in detail in Figure 7 and comprises the inductive resistance 45 provided with an insulated binding post 46 wit which the respective conductor 6 or 7 is connected, said post also supporting a spring 48 which sustains an armature 49 adjacent to the core of the resistance 45. The helix of resistance 45 is connected preferably through the spring to the binding post at one end and at the other end is grounded on the core of the resistance, the said core being grounded by ground conductor 44 which extends to the metallic plate 52 embedded in moist carbon or other inductive material buried in the earth. Each of the conductors 41, 42 and 44 is of iron, and in this connection I wish it understood that where I state the specific substance I am able to verify the accuracy of the statement by the results of tests which I have made, but of course I wish to include along with such substances al equivalents, as for instance, where iron is mentioned its byproducts, such as steel, and its equivalents such as nickel and other magnetic substances are intended to be comprehended. The cutout apparatus seen in detail in Figure 7 is employed particularly for insuring against high tension currents, it being obvious from the structure shown that when potential rises beyond the limit established by the tension of the spring sustaining the armature 40, the armature will be moved to a position contacting with the core of the cutout device and thereby directly close the ground connection for line wire 41 with conductor 44, eliminating the resistance of winding 45 and allowing the high tension current to be discharged to the ground. Immediately upon such discharge the winding 45 losing its current will allow the core to become demagnetized and release the armature 49 whereby the ground connection is substantially broken leaving only the connection through the winding 45 the resistance of which is sufficient for insuring against loss of low tension current.

In Figure 8 I have illustrated an apparatus which though apparently primitive in construction and arrangement comprehends the first successful embodiment which I produced in the course of discovery of the present invention, and it will be observed that the essential features of the invention are therein disclosed. The structure delineated in said figure consists of horseshoe magnets 54, 55, one facing north and the other south, that is, each opening in the respective directions indicated and the two being connected by an iron wire 55 which is uninsulated and wrapped about the respective magnets each end portion of the wire 55 being extended from the respective magnets to and connected with, as by being soldered to, a zinc plate 56, there being a plate 56 for each magnet and each plate being arranged longitudinally substantially parallel with the legs of the magnet and with the faces of the plate exposed toward the respective legs of the magnet, the plate being thus arranged endwise toward the north and south. An iron wire 57 connects the plates 56, the ends of the wire being preferably connected adjacent the outer ends of the plates but from experiment I find that the wire may be connected at practically any point to the plate. Lead wires 58 and 59 are connected respectively with the wires 55 and 57 and supply an alternating current at a comparatively low tension, and to control such current the wires 58 and 59 may be extended to a rectifier or combined rectifier and intensifier, as above set forth.

The tests which I have found successful with the apparatus seen in Figure 8 were carried out by the employment first of horseshoe magnets approximately 4 inches in length, the bar comprising the horseshoe being about one inch square, the zincs being dimensioned proportionately and from this apparatus with the employment of a single intensifier and rectifier, as above stated, I was able to obtain a constant current of 8 volts.

It should be obvious that the magnets forming one of the electrodes of this apparatus may be permanent or may be electromagnets, or a combination of the two.

While the magnets mentioned throughout the above may be formed of any magnetic substance, I find the best results obtained by the employment of the nickel chrome steel.

While the successful operation of the various devices which I have constructed embodying the present invention have not enabled me to arrive definitely and positively at fixed conclusion relative to the principles and theories of operation and the source from which current is supplied, I wish it to be understood that I consider myself as the first inventor of the general type hereinbefore described capable of producing commercially serviceable electricity, for which reason my claims hereinafter appended contemplate that I may utilize a wide range of equivalents so far as concerns details of construction suggested as preferably employed.

The current which I am able to obtain is dynamic in the sense that it is not static and its production is accomplished without chemical or mechanical action either incident to the actual chemical or mechanical motion or incident to changing caloric conditions so that the elimination of necessity for the use of chemical or mechanical action is to be considered as including the elimination of the necessity for the use of heat or varying degrees thereof.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is: --- [Claims not included here]

NOTES & COMMENTS

From the Article in *Tech. World Mag*.:

1. First demo model was powerful enough to spark a gas engine.
2. Second model developed 8 volts.
3. Demo model at Patent Office was elevated on short poles.
4. The model planned to power Phoenix AZ would be elevated 200 feet.
5. The Absorber "consists of a series of magnetized steel plates set in a circle (the manner of preparing them is kept secret)".
6. "[T]he magnetizing of one set of plates... is part of the secret of the treatment which makes it respond to the accumulations of the atmosphere".

From British Patent # 1098 (1913):

"I have been able... to produce from a very small apparatus at comparatively low elevation, say about 50 or 60 feet above the earth's surface, a substantially constant current at a commercially useable voltage and amperage".

"This current... is capable of being readily increased by additions of the unit elements in the apparatus".

Fig. 1 and Fig. 2 show the magnet poles are connected N-S by a thick iron rod (thick compared to the lines used for wires in the drawings).

No angle is specified for the V-shaped zinc plates. The article (but not the patent) states that the plates are magnetized (obviously not zinc). Zinc-galvanized steel? Will a thin film of Zn work? Or, powdered Zn in a binder (more surface area)? Or, zinc-galvanized iron wire in a coil?

The Palmer Craig device (www.rexresearch.com/craig/craig.htm) is powered by the terrestrial magnetic field, and employs a thin film of bismuth to capture the energy as diamagnetism. Perhaps this can be integrated with Meyers' device.

Figure 8 (the demonstration of principle) show uninsulated iron wire being used to connect the plates and magnets. The wire is wound around the Bloch wall area of the horseshoe magnets. Perhaps Coler-type windings around the poles could be used here (See: www.rexresearch.com/coler/coler.htm). Coler used copper plates as "condensers" in his device. Could copper plates be used for the Meyers device? Perhaps flat (Tesla non-inductive) coils could be integrated here.

"It is essential that the plates 3 be disposed substantially N and S with their flat faces approximately parallel to the adjacent faces of the co-operating magnets....

"I find that it is immaterial whether the N pole of one of the magnets is disposed to the N and the S pole to the S, or vice versa".

"[T]he magnets and zinc plates... produce electrical currents when disposed... N and S, but when disposed... E and W no such currents are produced".

"[E]levation is by no means vital, but... more efficient results are obtained by placing the zincs and magnets on elevated supports".

"The elements may be disposed in horizontal planes [or vertically]...".

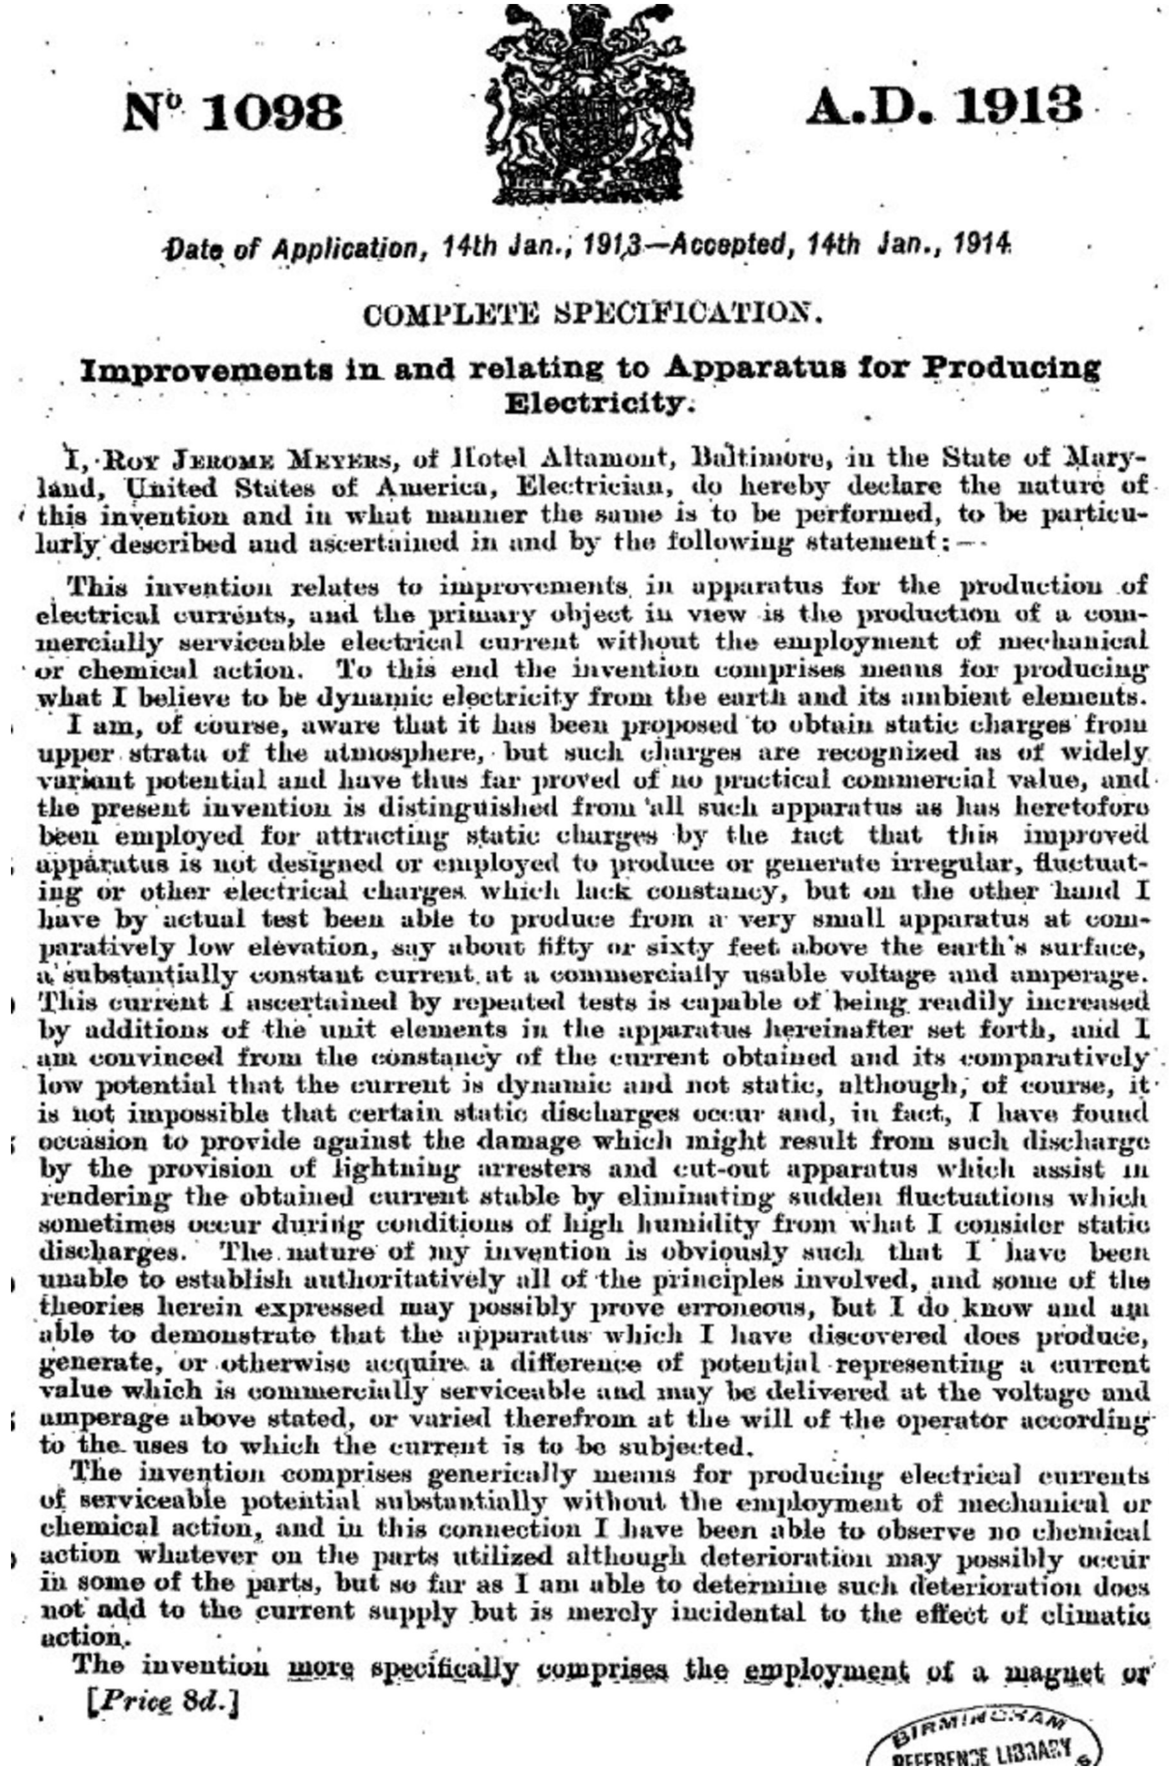
The "zinc plate 56... [is] arranged longitudinally substantially parallel with the legs of the magnet and with the faces of the plate exposed toward the respective legs of the magnet, the plate being thus arranged endwise toward the north and south".

The first model used "horseshoe magnets approximately 4 inches in length, the bar comprising the horseshoe being about one inch square, the zincs being dimensioned proportionately and from this apparatus with the employment of a single intensifier and rectifier, as above stated, I was able to obtain a constant current of 8 volts... [T]he magnets... may be permanent or may be electromagnets, or a combination of the two... I find the best results obtained by... nickel chrome steel".

Comments & Questions:

The rectifier is described as a preferred embodiment, but other designs also work. The Ed Gray capacitor design comes to mind (www.rexresearch.com/evgray/1gray.htm). The Tate Ambient Power Module also might apply (www.rexresearch/tate/tate.htm).

Would non-ferrous magnets work? Is there a frequency involved (oscilloscope tests)? Coler found that ferromagnetism has a resonant frequency about 180 KHz. Can the components be made adjustable for RLC-resonance?



Nº 1098 A.D. 1913

Date of Application, 14th Jan., 1913—Accepted, 14th Jan., 1914.

COMPLETE SPECIFICATION.

Improvements in and relating to Apparatus for Producing Electricity.

I, ROY JEROME MEYERS, of Hotel Altamont, Baltimore, in the State of Maryland, United States of America, Electrician, do hereby declare the nature of this invention and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:—

This invention relates to improvements in apparatus for the production of electrical currents, and the primary object in view is the production of a commercially serviceable electrical current without the employment of mechanical or chemical action. To this end the invention comprises means for producing what I believe to be dynamic electricity from the earth and its ambient elements. I am, of course, aware that it has been proposed to obtain static charges from upper strata of the atmosphere, but such charges are recognized as of widely variant potential and have thus far proved of no practical commercial value, and the present invention is distinguished from all such apparatus as has heretofore been employed for attracting static charges by the fact that this improved apparatus is not designed or employed to produce or generate irregular, fluctuating or other electrical charges which lack constancy, but on the other hand I have by actual test been able to produce from a very small apparatus at comparatively low elevation, say about fifty or sixty feet above the earth's surface, a substantially constant current at a commercially usable voltage and amperage. This current I ascertained by repeated tests is capable of being readily increased by additions of the unit elements in the apparatus hereinafter set forth, and I am convinced from the constancy of the current obtained and its comparatively low potential that the current is dynamic and not static, although, of course, it is not impossible that certain static discharges occur and, in fact, I have found occasion to provide against the damage which might result from such discharge by the provision of lightning arresters and cut-out apparatus which assist in rendering the obtained current stable by eliminating sudden fluctuations which sometimes occur during conditions of high humidity from what I consider static discharges. The nature of my invention is obviously such that I have been unable to establish authoritatively all of the principles involved, and some of the theories herein expressed may possibly prove erroneous, but I do know and am able to demonstrate that the apparatus which I have discovered does produce, generate, or otherwise acquire a difference of potential representing a current value which is commercially serviceable and may be delivered at the voltage and amperage above stated, or varied therefrom at the will of the operator according to the uses to which the current is to be subjected.

The invention comprises generically means for producing electrical currents of serviceable potential substantially without the employment of mechanical or chemical action, and in this connection I have been able to observe no chemical action whatever on the parts utilized although deterioration may possibly occur in some of the parts, but so far as I am able to determine such deterioration does not add to the current supply but is merely incidental to the effect of climatic action.

The invention more specifically comprises the employment of a magnet or

[*Price 8d.*]

BIRMINGHAM REFERENCE LIBRARY

magnets and a co-operating element, such as zinc disposed adjacent to the magnet or magnets and connected in such manner and arranged relative to the earth so as to produce current, my observation being that current is produced only when such magnets have their poles facing substantially to the north and south and the zincs are disposed substantially along the magnets.

The invention also comprehends other details of construction, combinations and arrangements of parts as will hereinafter be fully set forth and claimed.

In the accompanying drawings:

Figure 1 is a top plan view of an apparatus embodying the features of the present invention, the arrow accompanying the figure indicating substantially the geographical north, parts of the figure being diagrammatic for condensing the showing.

Figure 2 is a view in side elevation of the parts seen in plan in Figure 1.

Figure 3 is a vertical section taken on the plane indicated by the line 3—3 of Figure 2 and looking in the direction indicated by the arrow.

Figure 4 is a detail view partly in elevation and partly in section showing the detail connections of the converter and intensifier.

Figure 5 is a transverse section taken on the planes indicated by line 5—5 of Figure 4 and looking downwardly.

Figure 6 is an enlarged detail fragmentary section illustrating the parts at the juncture of the conductors and one of the intensifiers.

Figure 7 is an enlarged detail view partly in elevation and partly in section of one of the automatic cut-outs and

Figure 8 is a diagrammatic view of one of the simplest forms of embodiments of the invention.

Referring to the drawing by numerals, 1, 1 indicates magnets connected by a magnetic substance 2, preferably an iron wire. The magnets 1 are arranged in pairs, one pair being spaced beneath the other, and interposed between the magnets are zinc plates 3, 3 connected by an iron wire conductor 4. Suitable insulating supports 5 are arranged for sustaining the respective magnets 1 and plates 3, 3. Each plate 3 is preferably bent substantially into **V** form, as clearly seen in Figure 1, and the **V** of one of the plates opens or faces toward the north and the **V** of the other plate to the south. I have determined by experimentation that it is essential that the plates 3 be disposed substantially north and south with their flat faces approximately parallel to the adjacent faces of the co-operating magnets, although by experience I have not discovered any material difference in the current obtained when the plates are disposed slightly to one side of north and south, as for instance when disposed in the line of the magnetic polarity of the earth. The same is true with respect to the magnets 1, the said magnets being disposed substantially north and south for operative purposes, although I find that it is immaterial whether the north pole of one of the magnets is disposed to the north and the south pole to the south, or *vice versa*, and it is my conviction from experience that it is essential to have the magnets of each pair connected by magnetic material so that the magnets substantially become one with a pole exposed to the north and a pole exposed to the south. In Figure 1, I have indicated in full lines by the letters S and N the respective polarities of the magnets 1, and have indicated in dotted lines the other poles of those magnets when the connection 2 is severed. I have found that the magnets and zinc plates operate to produce, whether by collection or generation I am not certain, electrical currents when disposed substantially north and south, but when disposed substantially east and west no such currents are produced. I also find that the question of elevation is by no means vital, but it is true that more efficient results are obtained by placing the zincs and magnets on elevated supports. I furthermore find from tests that it is possible to obtain currents from the apparatus with the zincs and magnets disposed in a building or otherwise enclosed, although more efficient results are obtained by having the said elements arranged in the open.

While in Figures 1, 2 and 3, I have shown the magnets and the zinc plates as superimposed, it will be apparent, as hereinafter fully set forth, that these elements may be juxtaposed in horizontal planes, and substantially the same results will be secured. Furthermore, the magnets 1 with the interposed zincs 3, as shown in Figures 1, 2 and 3 merely represent a unit which may be repeated either horizontally or vertically for increasing the current supply, and when the unit is repeated the zinc plates are arranged alternating with the magnets throughout the entire series as hereinafter indicated.

A conductor 6 is connected in multiple with the conductors 2 and a conductor 7 is connected with conductor 4, the conductor 6 extending to one terminal of a rectifier which I have indicated by the general reference character 8, and the conductor 7 extending to the other terminal of said rectifier. The rectifier as seen in diagram in Figure 1 may assume any of several well known embodiments of the electrical valve type and may consist of four assymmetric cells or Cooper-Hewitt mercury vapor lamps connected as indicated in Figure 1 for permitting communication of the positive impulses from conductor 7 only to the line conductor 9 and the negative impulses from the conductor 7 only to the line conductor 10, and permitting the positive impulses from the conductor 6 only to the line conductor 9 and the negative impulses from conductor 6 only to the line conductor 10. The current from this rectifier may be delivered through the conductors 9 and 10 to any suitable source for consumption.

While the said rectifier 8 may consist of any of the known types, as above outlined, it preferably consists of a specially constructed rectifier which also has the capacity of intensifying the current and comprises specifically the elements shown in detail in Figures 4, 5 and 6 wherein I have disclosed the detail wiring of the rectifier when composed of four of the rectifying and intensifying elements instead of assymmetric cells or simple mercury vapor valves. As each of these structures is an exact embodiment of all the others, one only will be described, and the description will apply to all. The rectifying element of each construction consists of a mercury tube 11 which is preferably formed of copper but may be formed of glass or other suitable material, and comprises a cylinder having its end portions tapered and each terminating in an insulating plug or stopper 12. Through the upper stopper 12 is extended the electrode 13 which extends well into the tube and preferably substantially one-half the length thereof to a point adjacent the inner end of an opposing electrode 14 which latter electrode extends thence downwardly through the insulation 12 at the lower end of the tube. The tube 11 is supplied with mercury and is adapted to operate on the principle of the mercury vapor lamp, serving to rectify current by checking back impulses of one sign and permitting passage of impulses of the other. To avoid the necessity for utilizing a starter, as is common with the lamp type of electrical valve, the supply of mercury within the tube may be sufficient to contact with the lower end of the electrode 13 when current is not being supplied, so that as soon as current is passed from one electrode to the other sufficiently for volatilizing that portion of the mercury immediately adjacent the lower end of electrode 13, the structure begins its operation as a rectifier. The tube 11 is surrounded by a tube 15 which is preferably spaced from tube 11 sufficiently for allowing atmospheric or other cooling circulation to pass the tube 11. In some instances, it may be desirable to cool the tube 11 by a surrounding body of liquid, as hereinafter indicated. The tube 15 may be of insulating material but I find efficient results attained by the employment of a steel tube, and fixed to the ends of the tube are insulating disks 16, 16 forming a spool on which are wound twin wires 6^1 and 7^1, the wire 6^1 being connected at the inner helix of the coil with the outer end of the electrode 14, the lower portion of said electrode being extended to one side of the tube 11 and passed through an insulating sleeve 17 extending through the tube 15, and at its outer end merging into the adjacent end of the wire 6^1. The wire 7^1 extends directly from the outer portion of the spool through the several helices to a point adjacent the juncture of the electrode 14 with wire 6^1 and thence extends in mechanical parallelism with the wire throughout the coil, the wire 6^1 ending in a terminal 18 and the wire 7^1 ending in a terminal 19. For the sake of convenience of description and of tracing the circuits, each of the apparatus just above described and herein known as an intensifier and rectifier will be mentioned as A, B, C and D, respectively. Conductor 6 is formed with branches 20 and 21 and conductor 7 is formed with similar branches 22 and 23. Branch 20 from conductor 6 connects with conductor 7^1 of intensifier B and branch 21 of conductor 6 connects with the conductor 7^1 of intensifier C, while branch 22 of conductor 7 connects with conductor 7^1 of intensifier A and branch 23 of conductor 7 connects with conductor 7^1 of intensifier D. A conductor 27 is connected with terminal 19 of intensifier A and extends to and is connected with terminal 18 of intensifier C, and a conductor 28 is connected with the terminal 19 of intensifier C and extends to and is connected with electrode 13 of intensifier A. A conductor 29 extends from the terminal 19 of intensifier B to the terminal 18 of intensifier D and a conductor 30 extends from the terminal 19 of intensifier D to electrode 13 of intensifier B. Each electrode 13 is supported on a spider 13^1 resting on the upper disk 16 of the respective intensifier. Conductors 31 and 32 are connected with the terminals 18 of intensifiers A and B and are united to form the positive line wire 9 which co-operates with the negative line wire 10 and extends to any suitable point of consumption. The line wire 10 is provided with branches 35 and 36 extending to the electrodes 13 of intensifiers C and D for completing the negative side of the circuit.

Thus it will be seen that alternating currents produced in the wires 6 and 7 will be rectified and delivered in the form of a direct current through the line wires 9 and 10, and I find by experiment that the wires 6 and 7 should be of iron, preferably soft, and may of course be insulated, the other wiring not specified as iron being of copper or other suitable material.

In carrying out the operation as stated, the circuits may be traced as follows: A positive impulse starting at the zincs 3 is directed along conductor 7 to branch 23 to conductor 7^1 and the winding of intensifier D to terminal 19 through conductor 30 to electrode 13 of the rectifier of intensifier B through said rectifier to the conductor 6^1, through the winding thereof to the contact 18, conductor 32 and to the line wire 9. The next or negative impulse directed along conductor 7 cannot find its way along branch 23 and the circuit just above traced because it cannot pass across the rectifier of intensifier B but instead the negative impulse passes along conductor 22 to conductor 7 of intensifier A and the winding thereof to the contact 19 to conductor 27 to contact 18 of intensifier C, to the winding of the wire 6^1 thereof to the electrode 14 through the rectifier to the electrode 13 and conductor 36 to the line wire 10. A positive impulse delivered to wire 6 passes along the said wire to the branch 21 to the conductor 7^1 of intensifier C and the winding thereof to the contact 19, conductor 28, electrode 13 of the rectifier of intensifier A, electrode 14 thereof and conductor 6^1 to contact 18 and wire 31 to line wire 9. Obviously the positive impulse cannot pass along the wire 20 because of its inverse approach to the rectifier of intensifier B. The next impulse or negative impulse delivered to conductor 6 cannot pass along conductor 21 because of its connection with electrode 13 of the rectifier of intensifier A, but instead passes along conductor 20 to the wire 7^1 and its winding forming part of intensifier B to the contact 19 and conductor 29 to contact 18 and the winding of wire 6^1 of intensifier D to the electrode 14 and through the rectifier to the electrode 13 and conductor 35 to line wire 10. Thus the current is rectified and all positive impulses directed along one line and all negative impulses along the other line so that the potential difference between the two lines will be maximum for the given current of the alternating circuit. It is, of course, apparent that a less number of intensifiers with their accompanying rectifier elements may be employed with a sacrifice of the impulses which are checked back from a lack of ability to pass the respective rectifier elements, and in fact I have secured efficient results by the use of a single intensifier with its rectifier elements, as hereinafter set forth.

Grounding conductors 37 and 38 are connected respectively with the conductors 6 and 7 and are provided with the ordinary lightning arresters 39 and 40 respectively for protecting the circuit against high tension static charges.

Conductors 41 and 42 are connected respectively with the conductors 6 and 7 and each connects with an automatic cut-out 43 which is grounded as at 44. Each of said automatic cut-outs is exactly like the other and one of the same is shown in detail in Figure 7 and comprises the inductive resistance 45 provided with an insulated binding post 46 with which the respective conductor 6 or 7 is connected, said post also supporting a spring 48 which sustains an armature 49 adjacent the core of the resistance 45. The helix of resistance 45 is connected preferably through the spring to the binding post at one end and at the other end is grounded on the core of the resistance, the said core being grounded by ground conductor 44 which extends to the metallic plate 52 imbedded in moist carbon or other inductive material 53 buried in the earth. Each of the conductors 41, 42 and 44 is of iron, and in this connection I wish it understood that where I state the specific substance I am able to verify the accuracy of the statement by the results of tests which I have made, but of course I wish to include along with such substance all equivalents, as for instance, where iron is mentioned its by-products, such as steel, and its equivalents such as nickel and other magnetic substances are intended to be comprehended. The cut-out apparatus seen in detail in Figure 7 is employed particularly for insuring against high tension currents it being obvious from the structure shown that when potential rises beyond the limit established by the tension of the spring sustaining the armature 49, the armature will be moved to a position contacting with the core of the cut-out device and thereby directly close the ground connection for line wire 41 with conductor 44, eliminating the resistance of winding 45 and allowing the high tension current to be discharged to the ground. Immediately upon such discharge the winding 45 losing its current will allow the core to become demagnetized and release the armature 49 whereby the ground connection is substantially broken leaving only the connection through the winding 45 the resistance of which is sufficient for insuring against loss of low tension current.

In Figure 8 I have illustrated an apparatus which though apparently primitive in construction and arrangement comprehends the first successful embodiment which I produced in the course of the discovery of the present invention, and it will be observed that the essential features of the invention are therein disclosed. The structure delineated in said figure consists of horse shoe magnets 54, 54, one facing north and the other south, that is, each opening in the respective directions indicated and the two being connected by an iron wire 55 which is uninsulated and wrapped about the respective magnets at or adjacent the neutral zone thereof, and the wire 55 is preferably soldered to the respective magnets each end portion of the wire 55 being extended from the respective magnet to and connected with, as by being soldered to, a zinc plate 56, there being a plate 56 for each magnet and each plate being arranged longitudinally substantially parallel with the legs of the magnet and with the faces of the plate exposed toward the respective legs of the magnet, the plate being thus arranged endwise toward the north and south. An iron wire 57 connects the plates 56, the ends of the wire being preferably connected adjacent the outer ends of the plates but from experiment I find that the wire may be connected at practically any point to the plate. Lead wires 58 and 59 are connected respectively with the wires 55 and 57 and supply an alternating current ordinarily at a comparatively low tension, and to control such current the wires 58 and 59 may be extended to a rectifier or combined rectifier and intensifier, as above set forth.

The tests which I have found successful with the apparatus seen in Figure 8 were carried out by the employment first of horse shoe magnets approximately four inches in length, the bar comprising the horse shoe being about one inch square, the zincs being dimensioned proportionately and from this apparatus with the employment of a single intensifier and rectifier, as above stated, I was able to obtain a constant current of 8 volts.

It should be obvious that the magnets forming one of the electrodes of this apparatus may be permanent or may be electro-magnets, or a combination of the two.

While the magnets mentioned throughout the above may be formed of any magnetic substance, I find the best results obtained by the employment of the nickel chrome steel.

While the successful operation of the various devices which I have constructed embodying the present invention have not enabled me to arrive definitely and positively at fixed conclusions relative to the principles and theories of operation and the source from which current is supplied, I wish it to be understood that I consider myself as the first inventor of an apparatus of the general type hereinbefore described capable of producing commercially serviceable electricity, for which reason my claims hereinafter appended contemplate that I may utilize a wide range of equivalents so far as concerns details of construction suggested as preferably employed.

The current which I am able to obtain is dynamic in the sense that it is not static and its production is accomplished without chemical or mechanical action either incident to the actual chemical or mechanical motion or incident to changing calorific conditions so that the elimination of necessity for the use of chemical or mechanical action is to be considered as including the elimination of the necessity for the use of heat or varying degrees thereof.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—

1. Means for producing dynamic electricity without mechanical or chemical action.

2. Electricity producing means as claimed in Claim 1, characterized in that said means is capable of producing low tension current.

3. Electricity producing means as claimed in Claim 1, characterized in that said means comprises a magnet, and means co-operating with the latter.

4. Means as set forth in Claim 3, characterized in that the parts are stationary.

5. Means as claimed in Claim 3, characterized in that the magnet is disposed substantially north and south.

6. Means as claimed in Claims 1, 3 and 5, wherein the means coacting with the magnet is a metal and said parts are disposed substantially north and south.

7. Means as claimed in Claims 1, 3 and 6, in which the metal is zinc, and combined with conductors connected with the co-operating parts to deliver current therefrom.

8. Means as set forth in Claim 1, characterized in that said means comprises spaced magnets with an adjacent co-operating zinc, and an iron wire connecting the magnets, and means to deliver electrical current from said parts.

9. Means as set forth in Claim 8, characterized in that the current delivery means comprises an intensifier and rectifier.

10. Means as set forth in Claim 8, characterized in that the current delivery means comprises wires connected with the magnets and zinc, an electrical valve connected with one of said wires, and independent helices surrounding said valve, one of said helices being connected with the terminal of the valve at the opposite side from the contact of said wire and the other of said helices being connected with the other wire, the electrical valve comprising a mercury vapor rectifier.

11. The process of producing electricity comprising exposing a magnet and

co-operating means disposed substantially north and south and taking off current therefrom.

12. The process of producing electricity comprising disposing stationary elements in co-operative relation in respect to each other and with respect to the earth for giving off relatively low tension electrical current, substantially without chemical action.

13. Electricity producing means constructed and operating substantially as described with reference to the accompanying drawings.

Dated this 13th day of January, 1913.

"Picks Power from the Air"

by
Charlton Lawrence Edholm

A remarkable scene took place in the legislature of Arizona this spring when the lawmakers enthusiastically voted for the parole of a certain convict in the State penitentiary, granting him a leave of absence for 30 days and by means of private contributions raising a fund to defray his expenses to Washington DC and return.

The prisoner, Roy J. Meyers, is serving a 3-1/2 year sentence, but in spite of the fact that he bears the stigma of a convicted lawbreaker, he has demonstrated that a convict can be a useful member of society. During his imprisonment he perfected an electrical device of such original character as to arouse feelings of wonder and skepticism until experts had seen it in actual operation. It is a device to draw electricity from the atmosphere for light and power, and the 30-day parole was granted in order that the inventor might protect his rights through the patent office at Washington.

With the acquiescence of the legislature, Governor Hunt granted the parole and the prisoner was allowed to go free without any guard or any assurance but his word of honor that he would return. Two days before the period had elapsed, Meyer again presented himself before the governor, having accomplished his mission, and then returned to the penitentiary at Florence, where he continues to serve his sentence.

This, in brief, is the picturesque story which has called attention of the civilized world to a newly discovered electrical genius, and to another feature of the case which is of equal importance and human interest; namely, the enlightened policy pursued by our youngest State in its treatment of convicts...

Before entering the prison, Meyer had already applied for various patents, among them one for an improved trolley wheel head which prevents the trolley wheel from jumping the wire. Meyers had a conference with Superintendent Sims and Parole Clerk Sanders, and it was to these gentlemen that the inventor first explained the principles of his new device for securing electrical energy from the air. The officials were willing to give the man the opportunity to develop his plan and a little wooden building outside the walls was turned over to Meyers and was fitted up as a workshop and a laboratory. The first demonstration of the new apparatus was made shortly thereafter, the electricity drawn from the atmosphere being used to spark the gas engines of the pump house, and although the device was crude yet it did the work, and removed the doubts of his friends. Furtter development of the "absorber" followed, and his second model was constructed, and developed 8 volts. The machine came to the attention of the remarkable woman who brought his name before the legislature.

This was Miss Kate Barnard, State Commissioner of Charities and Corrections of Oklahoma, who was a guest of Mr. Sims, while studying prison conditions. She saw the machine at work, became familiar with the facts of Meyers' case, and was impressed by his rather blunt and unaffected personality, for Meyers has nothing of the polish or glibness of the poseur. He is a simple, earnest student of mechanical problems and not the sort of man to make a sentimental appeal for sympathy because of any grace of person or manner. Therefore it was the value of Meyers' invention, together with his essential integrity (in spite of his lapse) which so strongly impressed Miss Barnard that when she appeared before the Arizona legislature not long afterwards, addressing that body on the need of enlightened legislature along the line of her own work, she told the story of Roy Meyers and his epoch-making invention.

So, early in May, Meyers set out for Washington, unaccompanied.

In his own words: "When I arrived in Washington and laid my plans before the patent office experts, they merely smiled and told me that I would have to build a model and demonstrate my claims --- that it seemed strange that I, unknown as I am in the electrical world, should have accomplished the things for which Edison, Tesla and other experts have been striving for years.

"They could grasp the meaning of my drawings nor the explanation I tried to make to them. There was little time to spare, as I had only 20 days left of my leave, but I set to work in a few days was able to take a crude model around to the patent office to make a demonstration.

"Arriving at the patent office I telephoned to a friend who had been so kind as to introduce me and aid me in reaching the proper officials. The absorber was hoisted on two short poles and made to work. While they were as yet unable to understand the principles involved and hardly willing to believe their eyes, they were forced to admit that I had something new and different, and they told me that there would be no further objection; that I might file my application without further delay.

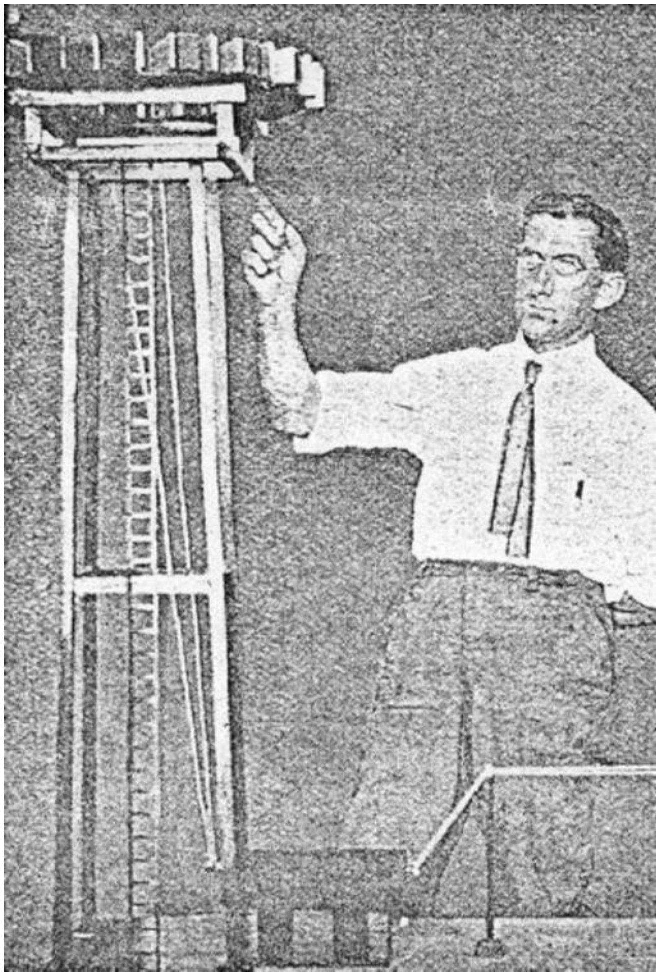
"I hope to construct my first large machine right here in Phoenix. I feel grateful; to Governor Hunt and others for what they have done for me and to the help they have given in securing protection I might not otherwise have had, and I am desirous of demonstrating this gratitude. I am going back to Florence today to resume the serving of my sentence, which will expire in 10 months. Then, here in Phoenix, I will begin the work of making my machines."

While there are some details of the device which the inventor refuses to make public, yet there are many general features that may be explained. It is planned that the machine, to be set up in Phoenix, will generate sufficient power to light the city, and will consist of a 200 foot tower upon which is placed the "absorber". The latter consists of a series of magnetized steel plates set in a circle (the manner of preparing them is kept secret) and this mechanism attracts the electricity from the atmosphere. This is carried by wires to a transformer in the engine house below and thence is applied to produce either power or light after the usual manner.

In an authorized statement Meyers says: "The flow of electricity is constant. When it emerges into the transformer it is in the form of a direct current. It will absorb the electricity day and night and will work whenever the wireless will work. I can put up a plant to supply such a building as the Adams Hotel for about $1500, and one of the principal items of the expense is the cost of the towers, the wires, the magnetizing of one set of plates, which is part of the secret of the treatment which makes it respond to the accumulations of the atmosphere.

"For use in the case of an electrical storm I have made what I call a modified form of circuit breaker, such as is commonly used as a lightning arrester on telegraph lines. In case of a storm the accumulator would suddenly become overcharged, possibly, and as the electricity would not of itself flow back into the air, the result might be disastrous. So I send it down into the ground, whenever the voltage rises above a certain amount."

Roy J. Meyers & the "Absorber"



Modern Electronics **(1914 ?)**

Electricity From Air New Great Discovery

by

Dr Leonard Keene Hirshberg

Working quietly in the heart of Baltimore for weeks on an invention which some critics say will revolutionize the method of converting electricity to practical use has been Roy J. Meyers, who like Benjamin Franklin, extracts the electric current from the air.

Mr Meyers invention was made last summer while he was confined in the penitentiary at Florence, Arizona. His first finished apparatus was made in Baltimore.

A practical, unlettered electrician, Mr Meyers, while in Arizona, was arrested on a comparatively minor charge and sent to the penitentiary. There he was placed in charge of the prison electrical plant, and there he says he made his discovery that the current which the civilized world is beginning to use most extensively for light and power could be transformed from the atmosphere without the aid of moving machines or batteries.

Miss Kate Barnard, Commissioner of Charities and Corrections, of Oklahoma, hearing of Meyers' invention and of his desire to have it patented, appeared before the Arizona Legislature to make an appeal in behalf of the young convict. As a result a special bill was passed which granted Meyers a month's leave of absence on parole. He went unaccompanied to Washington, filed his patent applications and returned to the penitentiary. Since then he has been indefinitely paroled.

He came to Baltimore as the place where he could easily obtain the mechanical parts needed to make a more nearly perfect machine than the crude model he has fashioned in the penitentiary workshop, and is making his headquarters here while working on his invention. With him is W.E. Chenot, who has been his assistant in assembling and testing the machine and who says that he has bought Meyers' patent rights for Germany.

They have proved beyond doubt that the invention is practical and that when finally brought to a state of perfection it will introduce a new epoch in the industrial use of electricity. By Westinghouse meters they tested the strength of the current gathered from the air, and with the use of only two of the four rectifying transformers the voltmeter recorded four and one-half volts, and the ammeter, which had the capacity of recording 75 amperes, was broken by the force of the current.

The machine itself is simple. It is in reality a transformer, which is familiar to anyone knowing anything at all about electricity in its practical uses. On a high tripod, which resembles somewhat the framework of a windmill tower, is the transformer, which Mr Meyers calls his 'absorber'. It is made up of an iron core, wrapped with copper wire. The secret of the invention is the manner in which the disks composing this 'absorber' are magnetized, and this secret Meyers says he found by accident while at work in prison.

What the machine, when finally perfected, will do is yet to be seen. Its inventor claims that it will greatly reduce the cost of making electricity. No batteries of any kind are needed, he says, and not a part of the machine turns upon the other. It is as durable, apparently, as an electric light pole. One of these machines, says Meyers, when perfected may be placed on a vehicle and transform enough electricity to give motive power, be that vehicle a locomotive or an automobile. He declared it can be placed on a building to furnish electric lights or power, and that the only wear will be upon the machinery which its current runs.

Meyers is 34 years old and he gained his knowledge of electricity by working in shops along the Pacific Coast. The depths of the mysteries of electricity he has not explored, but he is certain that he has found the means of absorbing it from the air and of converting it to the use of mankind.

British (GB) Patent # 191301098

Improvements in and Relating to Apparatus for Producing Electricity.

1-14-1914

Roy Jerome Meyers

Classification: - international: H05F7/00; H05F7/00; - european: H05F7/00
Application number: GBD191301098 19130114
Priority number(s): GBT191301098 19130114

Abstract ~ Vapour apparatus, arrangements of. - A rectifier for use with apparatus for producing electricity from the earth consists of mercury- vapour lamps constructed and arranged as shown in Fig. 4. Each lamp comprises two wires 6<1>, 7<1> wound around a steel tube 15 surrounding a

mercury tube 11 preferably of copper. The coil 6<1> is connected between the electrode 14 and the terminal 18, and the coil 7<1> between the terminals 19, 5. The coils 6<1>, 7<1> are preferably composed of soft iron. Reference has been directed by the Comp- troller to Specifications 16,709/87, 14,033/99, and 5457/11, [all in Class 53, Galvanic batteries], and 15,412/06.

British Patent # 1098

(January 14, 1913)

Improvements in and Relating to Apparatus for Producing Electricity

Roy Jerome Meyers

This invention relates to improvements in apparatus for the production of electrical currents, and the primary object in view is the production of a commercially serviceable electrical current without the employment of mechanical or chemical action. To this end the invention comprises means for producing what I believe to be dynamic electricity from the earth and its ambient elements.

I am, of course aware that it has been proposed to obtain static charges from upper strata of the atmosphere, but such charges are recognized as of widely variant potential and have thus far proved of no practical commercial value, and the present invention is distinguished from all such apparatus as has heretofore been employed for attracting static charges by the fact that this improved apparatus is not designed or employed to produce or generate irregular, fluctuating or other electrical charges which lack constancy, but on the other hand I have by actual test been able to produce from a very small apparatus at comparatively low elevation, say about 50 or 60 feet above the earth's surface, a substantially constant current at a commercially usable voltage and amperage. This current I ascertained by repeated tests is capable of being readily increased by additions of the unit elements in the apparatus hereinafter set forth, and I am convinced from the constancy of the current obtained and its comparatively low potential that the current is dynamic and not static, although, of course, it is not impossible that certain static discharges occur and, in fact, I have found occasion to provide against the damage which might result from such discharge by the provision of lightning arresters and cut-out apparatus which assist in rendering the obtained current stable by eliminating sudden fluctuations which sometimes occur during conditions of high humidity from what I consider static discharges. The nature of my invention is obviously such that I have been unable to establish authoritatively all of the principles involved, and some of the theories herein expressed may possibly prove erroneous, but I do know and am able to demonstrate that the apparatus which I have discovered does produce, generate, or otherwise acquire a difference of potential representing a current amperage above stated, or varied therefrom at the will of the operator according to the uses which the current is to be subjected.

The invention comprises generically means for producing electrical currents of serviceable potential substantially without the employment of mechanical or chemical action, and in this connection I have been able to observe no chemical action whatever on the parts utilized although deterioration may possibly occur in some of the parts, but so far as I am able to determine such deterioration does not add to the current supply but is merely incidental to the effect of climatic action.

The invention more specifically comprises the employment of a magnet or magnets and a co-operating element, such as zinc disposed adjacent to the magnet or magnets and connected in such manner and arranged relative to the earth so as to produce current, my observation being that current is produced only when such magnets have their poles facing substantially to the north and south and the zincs are disposed substantially along the magnets.

The invention also comprehends other details of construction, combinations and arrangements of parts as will hereinafter be fully set forth and claimed.

In the accompanying drawings:

Figure 1 is a top plan view of an apparatus embodying the features of the present invention, the arrow accompanying the figure indicating substantially the geographical north, parts of the figure being diagrammatic for condensing the showing.

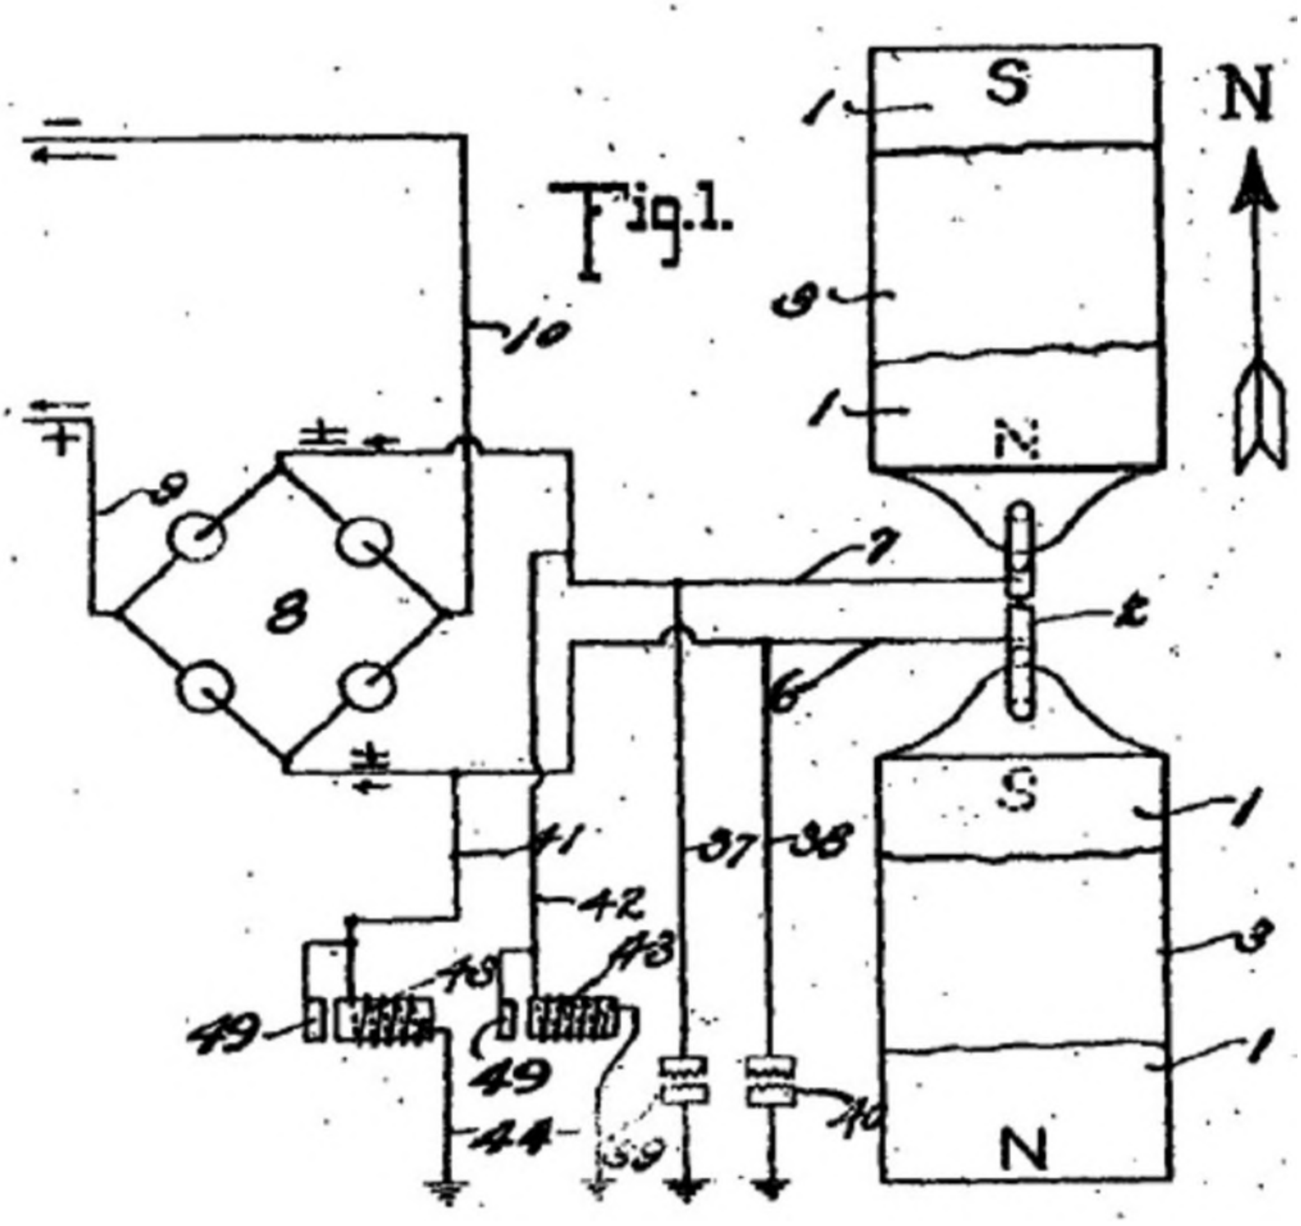


Figure 2 is a view is side elevation of the parts seen in plan in Figure 1.

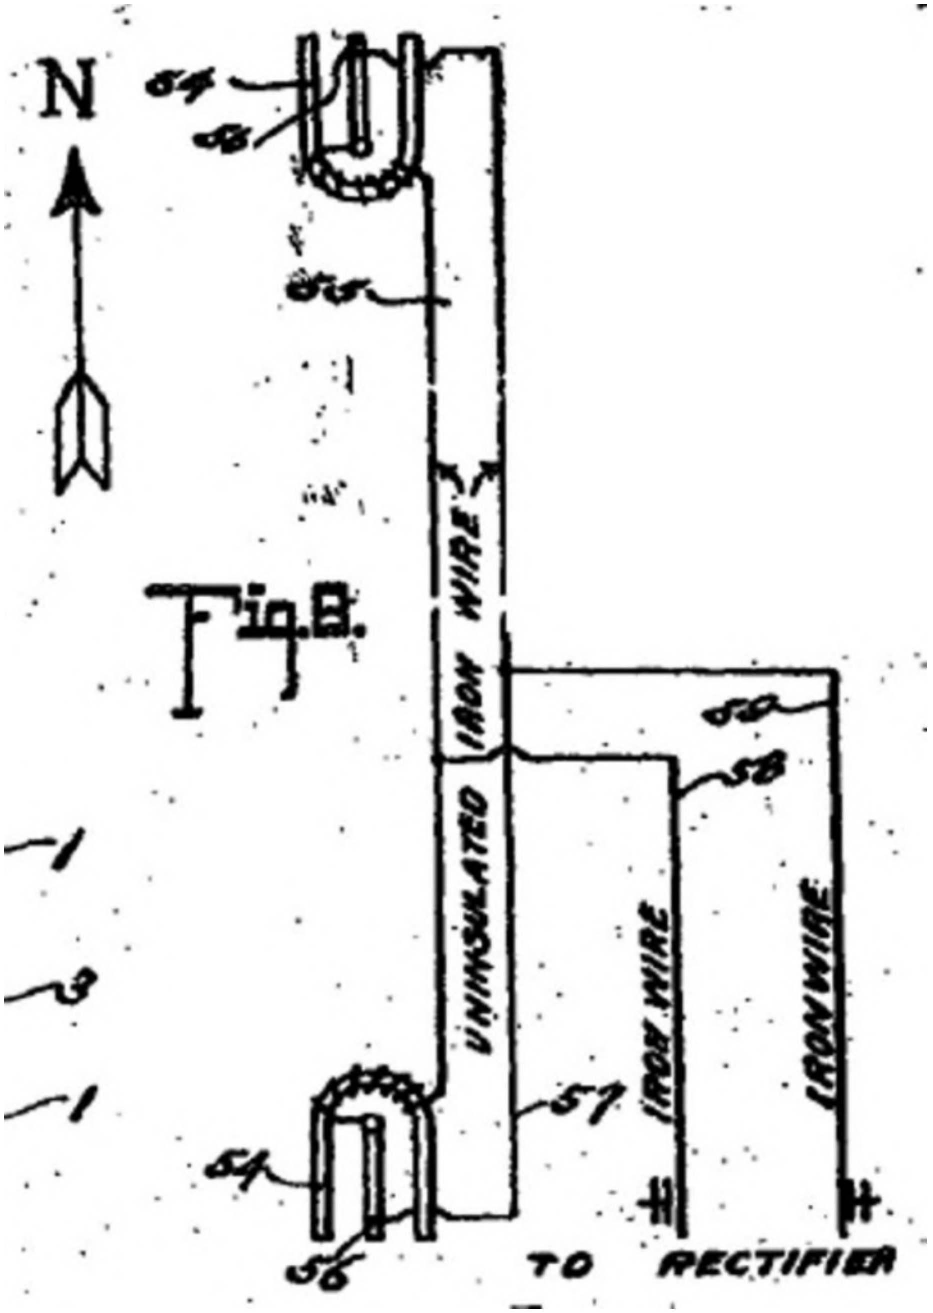

Fig. 8.

Referring to the drawing by numerals, 1,1 indicates magnets connected by a magnetic substance 2, preferably an iron wire. The magnets 1 are arranged in pairs, one pair being spaced beneath the other, and interposed between the magnets are zinc plates 3,3 connected by an iron wire conductor 4. Suitable insulating supports 5 are arranged for sustaining the respective magnets 1 and plates 3,3. Each plate 3 is preferably bent substantially into V form, as clearly seen in Figure 1, and the V1 of one of the plates opens or faces toward the north and the V of the other plate to the South. I have determined by experimentation that it is essential that the plates 3 be disposed substantially north and south with their flat faces approximately parallel to the adjacent faces of the co-operating magnets, although by experience I have not discovered any material difference in the current obtained when the plates are disposed slightly to one side of north and south, as for instance when the plates are disposed slightly to one side of north and south, as for instance when disposed in the line of the magnetic polarity of the earth. The same is true with respect to the magnets 1, the said magnets being disposed substantially north and south for operative purposes, although I find that it is immaterial whether the north pole of one of the magnets is disposed to the north and the south pole to the south, or vice versa, and it is my conviction from experience that it is essential to have the magnets of each pair connected by magnetic material so that the magnets substantially become one with a pole exposed to the north and a pole exposed to the north. In Figure 1, I have indicated in full lines by the letters 8 and N the respective polarities of the magnets 1, and have indicated in dotted lines the other pole of those magnets when the connection 2 is severed. I have found that the magnets and zinc plates operate to produce, whether by collection or generation I am not certain, electrical currents when disposed substantially north and south, but when disposed substantially east and west no such currents are produced. I also find that the question of elevation is by no means vital, but it is true that more efficient results are obtained by placing the zincs and magnets on elevated supports. I furthermore find from tests that it is possible to obtain currents from the apparatus with the zincs and magnets disposed in a building or otherwise enclosed, although more efficient results are obtained by having the said elements arranged in the open.

While in Figures 1, 2, and 3, I have shown the magnets and the zinc plates as superimposed, it will be apparent, as hereinafter fully set forth, that these elements may be juxtaposed in horizontal planes, and substantially the same results will be secured. Furthermore, the magnets 1 with the interposed zincs 3, as shown in Figures 1, 2 and 3 merely represent a unit which may be repeated either horizontally or vertically for increasing the current supply, and when the unit is repeated the zinc plates are arranged alternating with the magnets throughout the entire series as hereinafter indicated.

A conductor 6 is connected in multiple with the conductors 2 and a conductor 7 is connected with conductor 4, the conductor 6 extending to one terminal of a rectifier which I have indicated by the general reference character 8, and the conductor 7 extending to the other terminal of said rectifier. The rectifier as seen in diagram in Figure 1 may assume any of several well known embodiments of the electrical valve type and may consist of four asymmetric cells or Cooper-Hewitt mercury vapor lamps connected as indicated in Figure 1 for permitting communication of the positive impulses from the conductor 6 only to the line conductor 9 and the negative impulses from conductor 6 on only to the line conductor 10. The current from this rectifier may be delivered through the conductors 9 and 10 to any suitable source for consumption.

While the said rectifier 8 may consist of any of the known types, as above outlined, it preferably consists of a specially constructed rectifier which also has the capacity of intensifying the current and comprises specifically the elements shown in detail in Figures 4, 5, and 6 wherein I have disclosed the detail wiring of the rectifier when composed of four of the rectifying and intensify in elements instead of asymmetric cells or simple mercury vapor valves. As each of these structures is an exact embodiment of all the others, one only will be described, and the description will apply to all. The rectifying element of each construction consists of a mercury tube 11 which is preferably formed of glass or other suitable material, and comprises a cylinder having its end portions tapered and each terminating in an insulating plug or stopper 12. Through the upper stopper 12 is extended the electrode 13 which extends well into the tube and preferably substantially one-half the length thereof to a point adjacent the inner end of an opposing electrode 14 which latter electrode extends thence downwardly through the insulation 12 at the lower end of the tube. The tube 11 is supplied with mercury and is adapted to operate on the principle of the mercury vapor lamp, serving to rectify current by checking back impulses of one sign and permitting passage of impulses of the other. To avoid the necessity for utilizing a starter, as is common with the lamp type of electrical valve, the supply of mercury within the tube may be sufficient to contact with the lower end of the electrode 13 when current is not being supplied, so that as soon as current is passed from one electrode to the other sufficiently for volatilizing that portion of the mercury immediately adjacent the lower end of electrode 13, the structure begins its operation as a rectifier. The tube 11 is surrounded by a tube 15 which is preferably spaced from tube 11 sufficiently for allowing atmospheric or other cooling circulation to pass the tube 11. In some instances, it may be desirable to cool the tube 11 by a surrounding body of liquid, as hereinafter indicated. The tube 15 may be of insulating material but I find efficient results attained by the employment of a steel tube, and fixed to the ends of the of the tube are insulating disks 16, 16 forming a spool on which are wound twin wires 6^1 and 7^1, the wire 6^1 being connected at the inner helix of the coil with the outer end of the electrode 14, the lower portion of said electrode being extended to one side of the tube 11 and passed through an insulating sleeve 17 extending through the tube 15, and at its outer end merging into the adjacent end of the wire 6^1. The wire 7^1 extends directly from the outer portion of the spool through the several helices to a point adjacent the juncture of the electrode 14 with wire 6^1 and thence extends in mechanical parallelism with the wire throughout the coil, the wire 6^1 ending in a terminal 18 and the wire 7^1 ending in a terminal 19. For the sake of convenience of description and of tracing the circuits, each of the apparatus just above described and herein known as an intensifier and rectifier will be mentioned as A, B, C and D, respectively. Conductor 6 is formed with branches 20 and 21 and conductor 7 is formed with similar branches 22 and 23. Branch 20 from conductor 6 connects with conductor 7^1 of intensifier B and branch 21 of conductor 6 connects with the conductor 7^1 of intensifier C, while branch 22 of conductor 7 of intensifier C, while branch 22 of conductor 7 connects with conductor 7^1 of intensifier D. A conductor 27 is connected with terminal 19 of intensifier A and extends to and is connected with the terminal 18 of intensifier C, and a conductor 7 connects with conductor 7^1 of intensifier D. A conductor 27 is connected with terminal 19 of intensifier A. and extends to and is connected with terminal 18 of intensifier C, and a conductor 28 is connected with the terminal 19 of intensifier C and extends from the terminal 19 of intensifier B to the terminal 18 of intensifier D to electrode 13 of intensifier B. Each electrode 13 is supported on a spider 13^1 resting on the upper disk 16 of the respective intensifier. Conductors 31 and 32 are connected with the terminals 18 of intensifiers A and B and are united to form the positive line wire 9 which co-operates with the negative line wire 10 and extends to any suitable point of consumption. The line wire 10 is provided with branches 35 and 36 extending to the electrodes 13 of intensifiers C and D for completing the negative side of the circuit.

Thus it will be seen that alternating currents produced in the wires 6 and 7 will be rectified and delivered in the form of a direct current through the line wires 9 and 10, and I find by experiment that the wires 6 and 7 should be of iron, preferably soft, and may of course be insulated, the other wiring not specified as iron being of copper or other suitable material.

In carrying out the operation as stated, the circuits may be traced as follows: A positive impulse starting at the zincs 3 is directed along conductor 7 to branch 23 to conductor 7^1 and the winding of the rectifier of intensifier B through said rectifier to the conductor 6^1, through the winding thereof to the contact 18, conductor 32 and to the line wire 9. The next or negative impulse directed along conductor 7 cannot find its way along branch 23 and the circuit just above traced because it cannot pass across the rectifier of intensifier B but instead the negative impulse passes along conductor 22 to conductor 7 of intensifier A and the winding thereof to the contact 19 and to conductor 27 to contact 18 of intensifier C, to the winding of the wire 6^1 thereof to the electrode 14 through the rectifier to the of the electrode 13 and conductor of intensifier A, electrode 14 thereof and conductor 6^1 to contact 18 and wire 31 to line wire 9. Obviously the positive impulse cannot pass along the wire 20 because of its inverse approach to the rectifier of intensifier B. The next impulse or negative impulse delivered to conductor 6 cannot pass along conductor 21 because of its connection with electrode 13 of the rectifier of intensifier A, but instead passes along conductor 20 to the wire 7^1 and its winding forming part of intensifier B to the contact 19 and conductor 29 to contact 18 and the winding of wire 6^1 of intensifier D to the electrode 14 and through the rectifier to the electrode 13 and conductor 35 to line wire 10. Thus the current is rectified and all positive impulses directed along one line and all negative impulses along the other lie s that the potential difference between the two lines will be maximum for the given current of the alternating circuit. It is, of course, apparent that a less number of intensifiers with their accompanying rectifier elements may be employed with a sacrifice of the impulses which are checked back from a lack of ability to pass the respective rectifier elements, and in fact I have secured efficient results by the use of a single intensifier with its rectifier elements, as hereinafter set forth.

Grounding conductors 37 and 38 are connected respectively with the conductors 6 and 7 and are provided with the ordinary lightning arresters 39 and 40 respectively for protecting the circuit against high tension static charges.

Conductors 41 and 42 are connected respectively with the conductors 6 and 7 and each connects with an automatic cutout 43 which is grounded as at 4. Each of said automatic cutouts is exactly like the other and one of the same is shown in detail in Figure 7 and comprises the inductive resistance 45 provided with an insulated binding post 46 wit which the respective conductor 6 or 7 is connected, said post also supporting a spring 48 which sustains an armature 49 adjacent to the core of the resistance 45. The helix of resistance 45 is connected preferably through the spring to the binding post at one end and at the other end is grounded on the core of the resistance, the said core being grounded by ground conductor 44 which extends to the metallic plate 52 embedded in moist carbon or other inductive material buried in the earth. Each of the conductors 41, 42 and 44 is of iron, and in this connection I wish it understood that where I state the specific substance I am able to verify the accuracy of the statement by the results of tests which I have made, but of course I wish to include along with such substances al equivalents, as for instance, where iron is mentioned its byproducts, such as steel, and its equivalents such as nickel and other magnetic substances are intended to be comprehended. The cutout apparatus seen in detail in Figure 7 is employed particularly for insuring against high tension currents, it being obvious from the structure shown that when potential rises beyond the limit established by the tension of the spring sustaining the armature 40, the armature will be moved to a position contacting with the core of the cutout device and thereby directly close the ground connection for line wire 41 with conductor 44, eliminating the resistance of winding 45 and allowing the high tension current to be discharged to the ground. Immediately upon such discharge the winding 45 losing its current will allow the core to become demagnetized and release the armature 49 whereby the ground connection is substantially broken leaving only the connection through the winding 45 the resistance of which is sufficient for insuring against loss of low tension current.

In Figure 8 I have illustrated an apparatus which though apparently primitive in construction and arrangement comprehends the first successful embodiment which I produced in the course of discovery of the present invention, and it will be observed that the essential features of the invention are therein disclosed. The structure delineated in said figure consists of horseshoe magnets 54, 55, one facing north and the other south, that is, each opening in the respective directions indicated and the two being connected by an iron wire 55 which is uninsulated and wrapped about the respective magnets each end portion of the wire 55 being extended from the respective magnets to and connected with, as by being soldered to, a zinc plate 56, there being a plate 56 for each magnet and each plate being arranged longitudinally substantially parallel with the legs of the magnet and with the faces of the plate exposed toward the respective legs of the magnet, the plate being thus arranged endwise toward the north and south. An iron wire 57 connects the plates 56, the ends of the wire being preferably connected adjacent the outer ends of the plates but from experiment I find that the wire may be connected at practically any point to the plate. Lead wires 58 and 59 are connected respectively with the wires 55 and 57 and supply an alternating current at a comparatively low tension, and to control such current the wires 58 and 59 may be extended to a rectifier or combined rectifier and intensifier, as above set forth.

The tests which I have found successful with the apparatus seen in Figure 8 were carried out by the employment first of horseshoe magnets approximately 4 inches in length, the bar comprising the horseshoe being about one inch square, the zincs being dimensioned proportionately and from this apparatus with the employment of a single intensifier and rectifier, as above stated, I was able to obtain a constant current of 8 volts.

It should be obvious that the magnets forming one of the electrodes of this apparatus may be permanent or may be electromagnets, or a combination of the two.

While the magnets mentioned throughout the above may be formed of any magnetic substance, I find the best results obtained by the employment of the nickel chrome steel.

While the successful operation of the various devices which I have constructed embodying the present invention have not enabled me to arrive definitely and positively at fixed conclusion relative to the principles and theories of operation and the source from which current is supplied, I wish it to be understood that I consider myself as the first inventor of the general type hereinbefore described capable of producing commercially serviceable electricity, for which reason my claims hereinafter appended contemplate that I may utilize a wide range of equivalents so far as concerns details of construction suggested as preferably employed.

The current which I am able to obtain is dynamic in the sense that it is not static and its production is accomplished without chemical or mechanical action either incident to the actual chemical or mechanical motion or incident to changing caloric conditions so that the elimination of necessity for the use of chemical or mechanical action is to be considered as including the elimination of the necessity for the use of heat or varying degrees thereof.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is: --- [Claims not included here]

NOTES & COMMENTS

From the Article in *Tech. World Mag*.:

1. First demo model was powerful enough to spark a gas engine.
2. Second model developed 8 volts.
3. Demo model at Patent Office was elevated on short poles.
4. The model planned to power Phoenix AZ would be elevated 200 feet.
5. The Absorber "consists of a series of magnetized steel plates set in a circle (the manner of preparing them is kept secret)".
6. "[T]he magnetizing of one set of plates... is part of the secret of the treatment which makes it respond to the accumulations of the atmosphere".

From British Patent # 1098 (1913):

"I have been able... to produce from a very small apparatus at comparatively low elevation, say about 50 or 60 feet above the earth's surface, a substantially constant current at a commercially useable voltage and amperage".

"This current... is capable of being readily increased by additions of the unit elements in the apparatus".

Fig. 1 and Fig. 2 show the magnet poles are connected N-S by a thick iron rod (thick compared to the lines used for wires in the drawings).

No angle is specified for the V-shaped zinc plates. The article (but not the patent) states that the plates are magnetized (obviously not zinc). Zinc-galvanized steel? Will a thin film of Zn work? Or, powdered Zn in a binder (more surface area)? Or, zinc-galvanized iron wire in a coil?

The Palmer Craig device (www.rexresearch.com/craig/craig.htm) is powered by the terrestrial magnetic field, and employs a thin film of bismuth to capture the energy as diamagnetism. Perhaps this can be integrated with Meyers' device.

Figure 8 (the demonstration of principle) show uninsulated iron wire being used to connect the plates and magnets. The wire is wound around the Bloch wall area of the horseshoe magnets. Perhaps Coler-type windings around the poles could be used here (See: www.rexresearch.com/coler/coler.htm). Coler used copper plates as "condensers" in his device. Could copper plates be used for the Meyers device? Perhaps flat (Tesla non-inductive) coils could be integrated here.

"It is essential that the plates 3 be disposed substantially N and S with their flat faces approximately parallel to the adjacent faces of the co-operating magnets....

"I find that it is immaterial whether the N pole of one of the magnets is disposed to the N and the S pole to the S, or vice versa".

"[T]he magnets and zinc plates... produce electrical currents when disposed... N and S, but when disposed... E and W no such currents are produced".

"[E]levation is by no means vital, but... more efficient results are obtained by placing the zincs and magnets on elevated supports".

"The elements may be disposed in horizontal planes [or vertically]...".

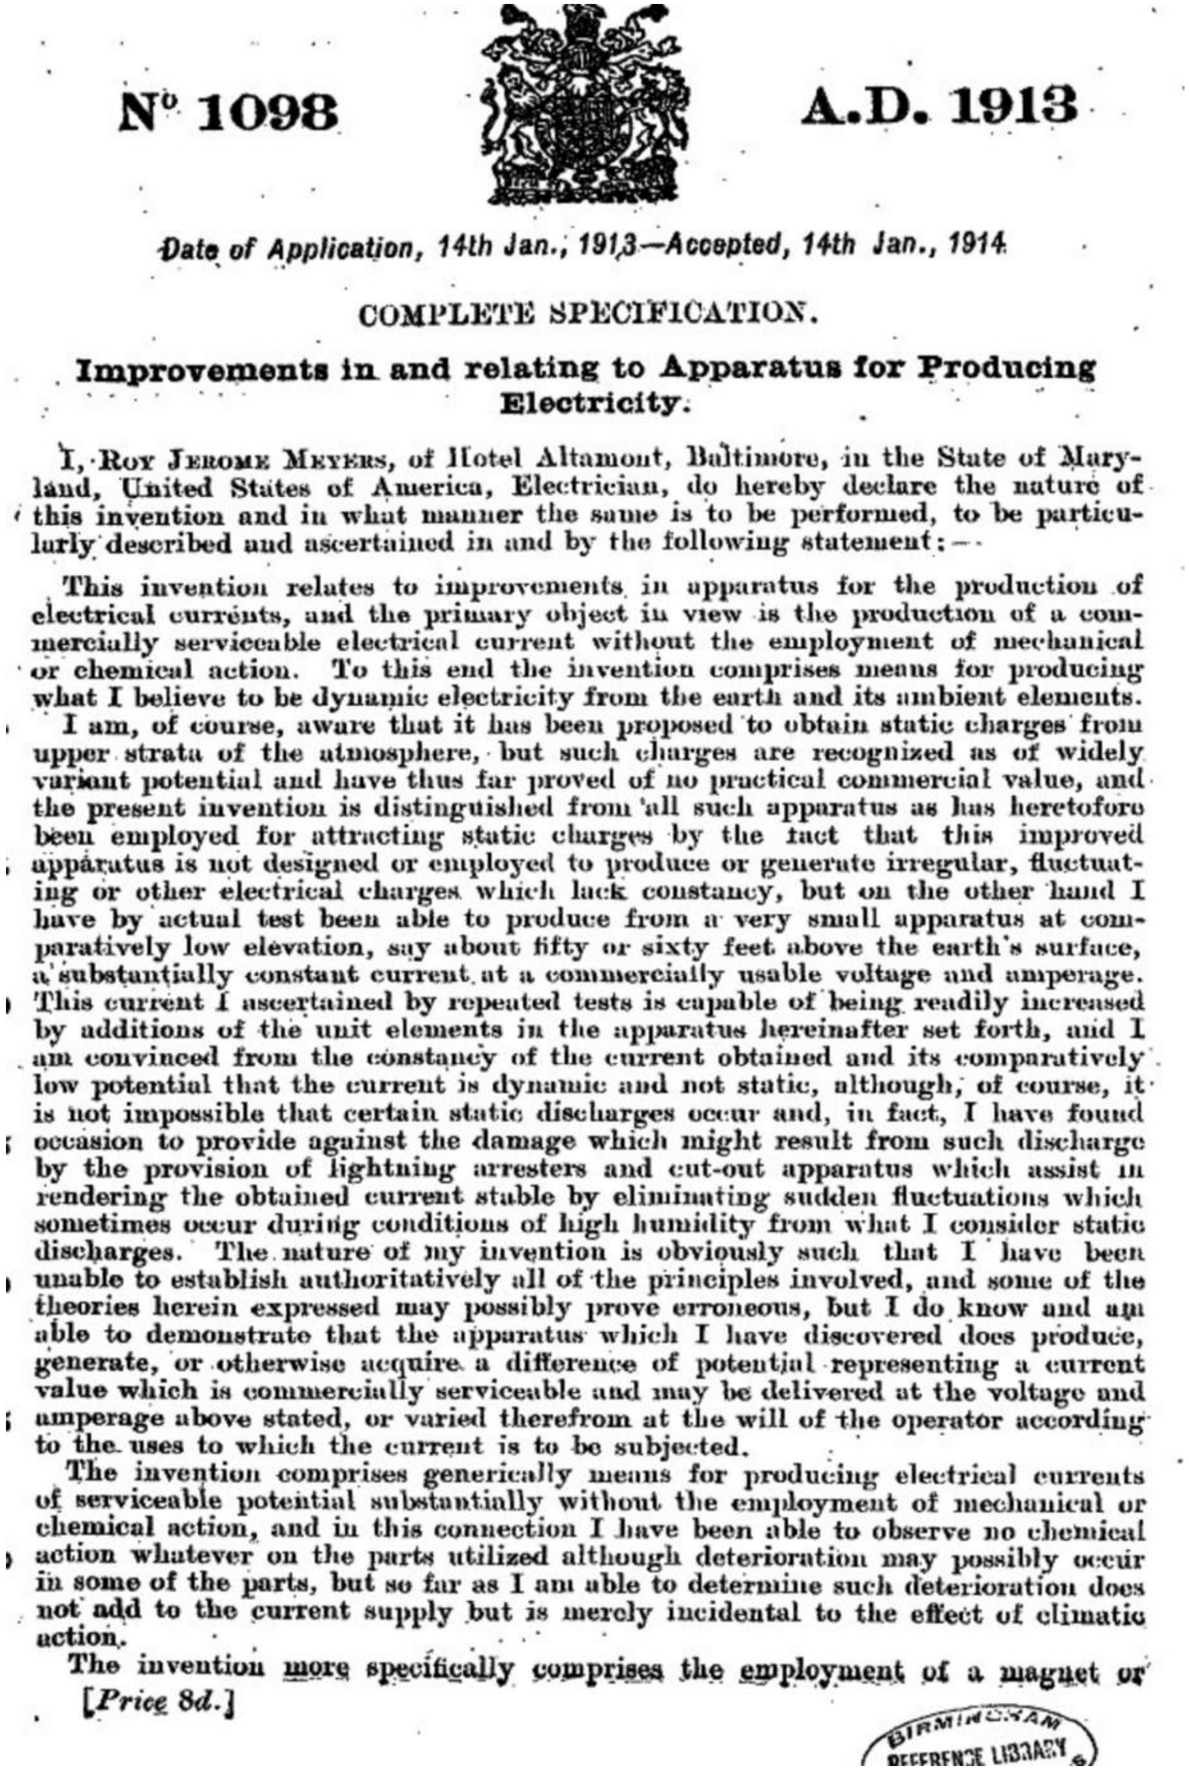
The "zinc plate 56... [is] arranged longitudinally substantially parallel with the legs of the magnet and with the faces of the plate exposed toward the respective legs of the magnet, the plate being thus arranged endwise toward the north and south".

The first model used "horseshoe magnets approximately 4 inches in length, the bar comprising the horseshoe being about one inch square, the zincs being dimensioned proportionately and from this apparatus with the employment of a single intensifier and rectifier, as above stated, I was able to obtain a constant current of 8 volts... [T]he magnets... may be permanent or may be electromagnets, or a combination of the two... I find the best results obtained by... nickel chrome steel".

Comments & Questions:

The rectifier is described as a preferred embodiment, but other designs also work. The Ed Gray capacitor design comes to mind (www.rexresearch.com/evgray/1gray.htm). The Tate Ambient Power Module also might apply (www.rexresearch/tate/tate.htm).

Would non-ferrous magnets work? Is there a frequency involved (oscilloscope tests)? Coler found that ferromagnetism has a resonant frequency about 180 KHz. Can the components be made adjustable for RLC-resonance?



Nº 1098 A.D. 1913

Date of Application, 14th Jan., 1913—Accepted, 14th Jan., 1914

COMPLETE SPECIFICATION.

Improvements in and relating to Apparatus for Producing Electricity.

I, ROY JEROME MEYERS, of Hotel Altamont, Baltimore, in the State of Maryland, United States of America, Electrician, do hereby declare the nature of this invention and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:—

This invention relates to improvements in apparatus for the production of electrical currents, and the primary object in view is the production of a commercially serviceable electrical current without the employment of mechanical or chemical action. To this end the invention comprises means for producing what I believe to be dynamic electricity from the earth and its ambient elements. I am, of course, aware that it has been proposed to obtain static charges from upper strata of the atmosphere, but such charges are recognized as of widely variant potential and have thus far proved of no practical commercial value, and the present invention is distinguished from all such apparatus as has heretofore been employed for attracting static charges by the fact that this improved apparatus is not designed or employed to produce or generate irregular, fluctuating or other electrical charges which lack constancy, but on the other hand I have by actual test been able to produce from a very small apparatus at comparatively low elevation, say about fifty or sixty feet above the earth's surface, a substantially constant current at a commercially usable voltage and amperage. This current I ascertained by repeated tests is capable of being readily increased by additions of the unit elements in the apparatus hereinafter set forth, and I am convinced from the constancy of the current obtained and its comparatively low potential that the current is dynamic and not static, although, of course, it is not impossible that certain static discharges occur and, in fact, I have found occasion to provide against the damage which might result from such discharge by the provision of lightning arresters and cut-out apparatus which assist in rendering the obtained current stable by eliminating sudden fluctuations which sometimes occur during conditions of high humidity from what I consider static discharges. The nature of my invention is obviously such that I have been unable to establish authoritatively all of the principles involved, and some of the theories herein expressed may possibly prove erroneous, but I do know and am able to demonstrate that the apparatus which I have discovered does produce, generate, or otherwise acquire a difference of potential representing a current value which is commercially serviceable and may be delivered at the voltage and amperage above stated, or varied therefrom at the will of the operator according to the uses to which the current is to be subjected.

The invention comprises generically means for producing electrical currents of serviceable potential substantially without the employment of mechanical or chemical action, and in this connection I have been able to observe no chemical action whatever on the parts utilized although deterioration may possibly occur in some of the parts, but so far as I am able to determine such deterioration does not add to the current supply but is merely incidental to the effect of climatic action.

The invention more specifically comprises the employment of a magnet or

[*Price 8d.*]

BIRMINGHAM REFERENCE LIBRARY

magnets and a co-operating element, such as zinc disposed adjacent to the magnet or magnets and connected in such manner and arranged relative to the earth so as to produce current, my observation being that current is produced only when such magnets have their poles facing substantially to the north and south and the zincs are disposed substantially along the magnets.

The invention also comprehends other details of construction, combinations and arrangements of parts as will hereinafter be fully set forth and claimed.

In the accompanying drawings:

Figure 1 is a top plan view of an apparatus embodying the features of the present invention, the arrow accompanying the figure indicating substantially the geographical north, parts of the figure being diagrammatic for condensing the showing.

Figure 2 is a view in side elevation of the parts seen in plan in Figure 1.

Figure 3 is a vertical section taken on the plane indicated by the line 3—3 of Figure 2 and looking in the direction indicated by the arrow.

Figure 4 is a detail view partly in elevation and partly in section showing the detail connections of the converter and intensifier.

Figure 5 is a transverse section taken on the planes indicated by line 5—5 of Figure 4 and looking downwardly.

Figure 6 is an enlarged detail fragmentary section illustrating the parts at the juncture of the conductors and one of the intensifiers.

Figure 7 is an enlarged detail view partly in elevation and partly in section of one of the automatic cut-outs and

Figure 8 is a diagrammatic view of one of the simplest forms of embodiments of the invention.

Referring to the drawing by numerals, 1, 1 indicates magnets connected by a magnetic substance 2, preferably an iron wire. The magnets 1 are arranged in pairs, one pair being spaced beneath the other, and interposed between the magnets are zinc plates 3, 3 connected by an iron wire conductor 4. Suitable insulating supports 5 are arranged for sustaining the respective magnets 1 and plates 3, 3. Each plate 3 is preferably bent substantially into **V** form, as clearly seen in Figure 1, and the **V** of one of the plates opens or faces toward the north and the **V** of the other plate to the south. I have determined by experimentation that it is essential that the plates 3 be disposed substantially north and south with their flat faces approximately parallel to the adjacent faces of the co-operating magnets, although by experience I have not discovered any material difference in the current obtained when the plates are disposed slightly to one side of north and south, as for instance when disposed in the line of the magnetic polarity of the earth. The same is true with respect to the magnets 1, the said magnets being disposed substantially north and south for operative purposes, although I find that it is immaterial whether the north pole of one of the magnets is disposed to the north and the south pole to the south, or *vice versa*, and it is my conviction from experience that it is essential to have the magnets of each pair connected by magnetic material so that the magnets substantially become one with a pole exposed to the north and a pole exposed to the south. In Figure 1, I have indicated in full lines by the letters S and N the respective polarities of the magnets 1, and have indicated in dotted lines the other poles of those magnets when the connection 2 is severed. I have found that the magnets and zinc plates operate to produce, whether by collection or generation I am not certain, electrical currents when disposed substantially north and south, but when disposed substantially east and west no such currents are produced. I also find that the question of elevation is by no means vital, but it is true that more efficient results are obtained by placing the zincs and magnets on elevated supports. I furthermore find from tests that it is possible to obtain currents from the apparatus with the zincs and magnets disposed in a building or otherwise enclosed, although more efficient results are obtained by having the said elements arranged in the open.

While in Figures 1, 2 and 3, I have shown the magnets and the zinc plates as superimposed, it will be apparent, as hereinafter fully set forth, that these elements may be juxtaposed in horizontal planes, and substantially the same results will be secured. Furthermore, the magnets 1 with the interposed zincs 3, as shown in Figures 1, 2 and 3 merely represent a unit which may be repeated either horizontally or vertically for increasing the current supply, and when the unit is repeated the zinc plates are arranged alternating with the magnets throughout the entire series as hereinafter indicated.

A conductor 6 is connected in multiple with the conductors 2 and a conductor 7 is connected with conductor 4, the conductor 6 extending to one terminal of a rectifier which I have indicated by the general reference character 8, and the conductor 7 extending to the other terminal of said rectifier. The rectifier as seen in diagram in Figure 1 may assume any of several well known embodiments of the electrical valve type and may consist of four assymmetric cells or Cooper-Hewitt mercury vapor lamps connected as indicated in Figure 1 for permitting communication of the positive impulses from conductor 7 only to the line conductor 9 and the negative impulses from the conductor 7 only to the line conductor 10, and permitting the positive impulses from the conductor 6 only to the line conductor 9 and the negative impulses from conductor 6 only to the line conductor 10. The current from this rectifier may be delivered through the conductors 9 and 10 to any suitable source for consumption.

While the said rectifier 8 may consist of any of the known types, as above outlined, it preferably consists of a specially constructed rectifier which also has the capacity of intensifying the current and comprises specifically the elements shown in detail in Figures 4, 5 and 6 wherein I have disclosed the detail wiring of the rectifier when composed of four of the rectifying and intensifying elements instead of assymmetric cells or simple mercury vapor valves. As each of these structures is an exact embodiment of all the others, one only will be described, and the description will apply to all. The rectifying element of each construction consists of a mercury tube 11 which is preferably formed of copper but may be formed of glass or other suitable material, and comprises a cylinder having its end portions tapered and each terminating in an insulating plug or stopper 12. Through the upper stopper 12 is extended the electrode 13 which extends well into the tube and preferably substantially one-half the length thereof to a point adjacent the inner end of an opposing electrode 14 which latter electrode extends thence downwardly through the insulation 12 at the lower end of the tube. The tube 11 is supplied with mercury and is adapted to operate on the principle of the mercury vapor lamp, serving to rectify current by checking back impulses of one sign and permitting passage of impulses of the other. To avoid the necessity for utilizing a starter, as is common with the lamp type of electrical valve, the supply of mercury within the tube may be sufficient to contact with the lower end of the electrode 13 when current is not being supplied, so that as soon as current is passed from one electrode to the other sufficiently for volatilizing that portion of the mercury immediately adjacent the lower end of electrode 13, the structure begins its operation as a rectifier. The tube 11 is surrounded by a tube 15 which is preferably spaced from tube 11 sufficiently for allowing atmospheric or other cooling circulation to pass the tube 11. In some instances, it may be desirable to cool the tube 11 by a surrounding body of liquid, as hereinafter indicated. The tube 15 may be of insulating material but I find efficient results attained by the employment of a steel tube, and fixed to the ends of the tube are insulating disks 16, 16 forming a spool on which are wound twin wires 6^1 and 7^1, the wire 6^1 being connected at the inner helix of the coil with the outer end of the electrode 14, the lower portion of said electrode being extended to one side of the tube 11 and passed through an insulating sleeve 17 extending through the tube 15, and at its outer end merging into the adjacent end of the wire 6^1. The wire 7^1 extends directly from the outer portion of the spool through the several helices to a point adjacent the juncture of the electrode 14 with wire 6^1 and thence extends in mechanical parallelism with the wire throughout the coil; the wire 6^1 ending in a terminal 18 and the wire 7^1 ending in a terminal 19. For the sake of convenience of description and of tracing the circuits, each of the apparatus just above described and herein known as an intensifier and rectifier will be mentioned as A, B, C and D, respectively. Conductor 6 is formed with branches 20 and 21 and conductor 7 is formed with similar branches 22 and 23. Branch 20 from conductor 6 connects with conductor 7^1 of intensifier B and branch 21 of conductor 6 connects with the conductor 7^1 of intensifier C, while branch 22 of conductor 7 connects with conductor 7^1 of intensifier A and branch 23 of conductor 7 connects with conductor 7^1 of intensifier D. A conductor 27 is connected with terminal 19 of intensifier A and extends to and is connected with terminal 18 of intensifier C, and a conductor 28 is connected with the terminal 19 of intensifier C and extends to and is connected with electrode 13 of intensifier A. A conductor 29 extends from the terminal 19 of intensifier B to the terminal 18 of intensifier D and a conductor 30 extends from the terminal 19 of intensifier D to electrode 13 of intensifier B. Each electrode 13 is supported on a spider 13^1 resting on the upper disk 16 of the respective intensifier. Conductors 31 and 32 are connected with the terminals 18 of intensifiers A and B and are united to form the positive line wire 9 which co-operates with the negative line wire 10 and extends to any suitable point of consumption. The line wire 10 is provided with branches 35 and 36 extending to the electrodes 13 of intensifiers C and D for completing the negative side of the circuit.

Thus it will be seen that alternating currents produced in the wires 6 and 7 will be rectified and delivered in the form of a direct current through the line wires 9 and 10, and I find by experiment that the wires 6 and 7 should be of iron, preferably soft, and may of course be insulated, the other wiring not specified as iron being of copper or other suitable material.

In carrying out the operation as stated, the circuits may be traced as follows: A positive impulse starting at the zincs 3 is directed along conductor 7 to branch 23 to conductor 7^1 and the winding of intensifier D to terminal 19 through conductor 30 to electrode 13 of the rectifier of intensifier B through said rectifier to the conductor 6^1, through the winding thereof to the contact 18, conductor 32 and to the line wire 9. The next or negative impulse directed along conductor 7 cannot find its way along branch 23 and the circuit just above traced because it cannot pass across the rectifier of intensifier B but instead the negative impulse passes along conductor 22 to conductor 7 of intensifier A and the winding thereof to the contact 19 to conductor 27 to contact 18 of intensifier C, to the winding of the wire 6^1 thereof to the electrode 14 through the rectifier to the electrode 13 and conductor 36 to the line wire 10. A positive impulse delivered to wire 6 passes along the said wire to the branch 21 to the conductor 7^1 of intensifier C and the winding thereof to the contact 19, conductor 28, electrode 13 of the rectifier of intensifier A, electrode 14 thereof and conductor 6^1 to contact 18 and wire 31 to line wire 9. Obviously the positive impulse cannot pass along the wire 20 because of its inverse approach to the rectifier of intensifier B. The next impulse or negative impulse delivered to conductor 6 cannot pass along conductor 21 because of its connection with electrode 13 of the rectifier of intensifier A, but instead passes along conductor 20 to the wire 7^1 and its winding forming part of intensifier B to the contact 19 and conductor 29 to contact 18 and the winding of wire 6^1 of intensifier D to the electrode 14 and through the rectifier to the electrode 13 and conductor 35 to line wire 10. Thus the current is rectified and all positive impulses directed along one line and all negative impulses along the other line so that the potential difference between the two lines will be maximum for the given current of the alternating circuit. It is, of course, apparent that a less number of intensifiers with their accompanying rectifier elements may be employed with a sacrifice of the impulses which are checked back from a lack of ability to pass the respective rectifier elements, and in fact I have secured efficient results by the use of a single intensifier with its rectifier elements, as hereinafter set forth.

Grounding conductors 37 and 38 are connected respectively with the conductors 6 and 7 and are provided with the ordinary lightning arresters 39 and 40 respectively for protecting the circuit against high tension static charges.

Conductors 41 and 42 are connected respectively with the conductors 6 and 7 and each connects with an automatic cut-out 43 which is grounded as at 44. Each of said automatic cut-outs is exactly like the other and one of the same is shown in detail in Figure 7 and comprises the inductive resistance 45 provided with an insulated binding post 46 with which the respective conductor 6 or 7 is connected, said post also supporting a spring 48 which sustains an armature 49 adjacent the core of the resistance 45. The helix of resistance 45 is connected preferably through the spring to the binding post at one end and at the other end is grounded on the core of the resistance, the said core being grounded by ground conductor 44 which extends to the metallic plate 52 imbedded in moist carbon or other inductive material 53 buried in the earth. Each of the conductors 41, 42 and 44 is of iron, and in this connection I wish it understood that where I state the specific substance I am able to verify the accuracy of the statement by the results of tests which I have made, but of course I wish to include along with such substance all equivalents, as for instance, where iron is mentioned its by-products, such as steel, and its equivalents such as nickel and other magnetic substances are intended to be comprehended. The cut-out apparatus seen in detail in Figure 7 is employed particularly for insuring against high tension currents, it being obvious from the structure shown that when potential rises beyond the limit established by the tension of the spring sustaining the armature 49, the armature will be moved to a position contacting with the core of the cut-out device and thereby directly close the ground connection for line wire 41 with conductor 44, eliminating the resistance of winding 45 and allowing the high tension current to be discharged to the ground. Immediately upon such discharge the winding 45 losing its current will allow the core to become demagnetized and release the armature 49 whereby the ground connection is substantially broken leaving only the connection through the winding 45 the resistance of which is sufficient for insuring against loss of low tension current.

In Figure 8 I have illustrated an apparatus which though apparently primitive in construction and arrangement comprehends the first successful embodiment which I produced in the course of the discovery of the present invention, and it will be observed that the essential features of the invention are therein disclosed. The structure delineated in said figure consists of horse shoe magnets 54, 54, one facing north and the other south, that is, each opening in the respective directions indicated and the two being connected by an iron wire 55 which is uninsulated and wrapped about the respective magnets at or adjacent the neutral zone thereof, and the wire 55 is preferably soldered to the respective magnets each end portion of the wire 55 being extended from the respective magnet to and connected with, as by being soldered to, a zinc plate 56, there being a plate 56 for each magnet and each plate being arranged longitudinally substantially parallel with the legs of the magnet and with the faces of the plate exposed toward the respective legs of the magnet, the plate being thus arranged endwise toward the north and south. An iron wire 57 connects the plates 56, the ends of the wire being preferably connected adjacent the outer ends of the plates but from experiment I find that the wire may be connected at practically any point to the plate. Lead wires 58 and 59 are connected respectively with the wires 55 and 57 and supply an alternating current ordinarily at a comparatively low tension, and to control such current the wires 58 and 59 may be extended to a rectifier or combined rectifier and intensifier, as above set forth.

The tests which I have found successful with the apparatus seen in Figure 8 were carried out by the employment first of horse shoe magnets approximately four inches in length, the bar comprising the horse shoe being about one inch square, the zincs being dimensioned proportionately and from this apparatus with the employment of a single intensifier and rectifier, as above stated, I was able to obtain a constant current of 8 volts.

It should be obvious that the magnets forming one of the electrodes of this apparatus may be permanent or may be electro-magnets, or a combination of the two.

While the magnets mentioned throughout the above may be formed of any magnetic substance, I find the best results obtained by the employment of the nickel chromo steel.

While the successful operation of the various devices which I have constructed embodying the present invention have not enabled me to arrive definitely and positively at fixed conclusions relative to the principles and theories of operation and the source from which current is supplied, I wish it to be understood that I consider myself as the first inventor of an apparatus of the general type hereinbefore described capable of producing commercially serviceable electricity, for which reason my claims hereinafter appended contemplate that I may utilize a wide range of equivalents so far as concerns details of construction suggested as preferably employed.

The current which I am able to obtain is dynamic in the sense that it is not static and its production is accomplished without chemical or mechanical action either incident to the actual chemical or mechanical motion or incident to changing calorific conditions so that the elimination of necessity for the use of chemical or mechanical action is to be considered as including the elimination of the necessity for the use of heat or varying degrees thereof.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—

1. Means for producing dynamic electricity without mechanical or chemical action.
2. Electricity producing means as claimed in Claim 1, characterized in that said means is capable of producing low tension current.
3. Electricity producing means as claimed in Claim 1, characterized in that said means comprises a magnet, and means co-operating with the latter.
4. Means as set forth in Claim 3, characterized in that the parts are stationary.
5. Means as claimed in Claim 3, characterized in that the magnet is disposed substantially north and south.
6. Means as claimed in Claims 1, 3 and 5, wherein the means coacting with the magnet is a metal and said parts are disposed substantially north and south.
7. Means as claimed in Claims 1, 3 and 6, in which the metal is zinc, and combined with conductors connected with the co-operating parts to deliver current therefrom.
8. Means as set forth in Claim 1, characterized in that said means comprises spaced magnets with an adjacent co-operating zinc, and an iron wire connecting the magnets, and means to deliver electrical current from said parts.
9. Means as set forth in Claim 8, characterized in that the current delivery means comprises an intensifier and rectifier.
10. Means as set forth in Claim 8, characterized in that the current delivery means comprises wires connected with the magnets and zinc, an electrical valve connected with one of said wires, and independent helices surrounding said valve, one of said helices being connected with the terminal of the valve at the opposite side from the contact of said wire and the other of said helices being connected with the other wire, the electrical valve comprising a mercury vapor rectifier.
11. The process of producing electricity comprising exposing a magnet and

co-operating means disposed substantially north and south and taking off current therefrom.

12. The process of producing electricity comprising disposing stationary elements in co-operative relation in respect to each other and with respect to the earth for giving off relatively low tension electrical current, substantially without chemical action.

13. Electricity producing means constructed and operating substantially as described with reference to the accompanying drawings.

Dated this 13th day of January, 1913.

Roy J. Meyers Absorber, GB Patent 191301098.

This device was brought to my attention by Grumage. Here is my take on why it worked.

In its simplest form the device consists of two horseshoe magnets, some zinc plates and some uninsulated iron wire. The iron wire is wound around the curved ends of the horseshoe magnet and connected to the zinc plates as shown in figure 1. The system has to be aligned with the earth's magnetic field.

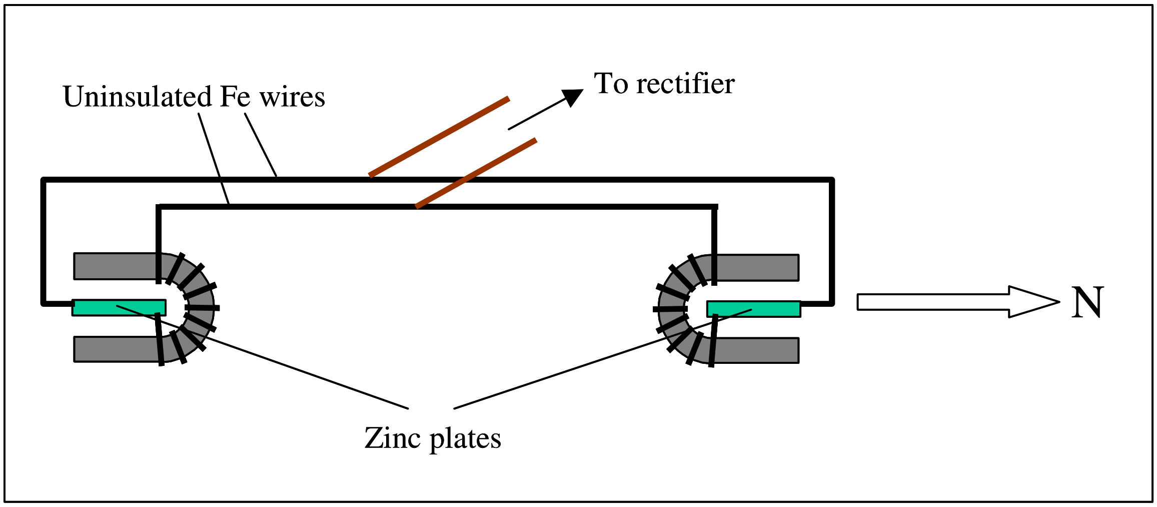

Figure 1. Simple Scheme reported to supply alternating current at low voltage

At first sight this seems incapable of providing alternating voltage but here is a possible explanation. If you follow the magnetization axis of each horseshoe it is seen that the earth's field supplies a magnetic gradient around the curved section, hence spin polarized conduction electrons therein will be dragged along thus creating a tiny potential difference between the two legs of each magnet. The iron wires wound over that curved end do nothing except create contact points at the ends of each curvature. We can discount any galvanic potential between iron wire and magnet since the magnets used were of magnetized steel. However we cannot ignore the galvanic potential between the zinc and the iron connection, or indeed the solder used for the connection. Although the two connections to the zinc would normally result in a zero overall potential, there exists a difference in the magnetic field at each end of the zinc, which could result in a significant (but low) voltage present. This magneto-Seebeck effect is a fairly new phenomenon and would not have been known in 1913 when the patent application was made. Also unknown at that time was the presence of spin-polarized conduction electrons.

This all predicts the presence of DC voltage, so how could this become AC? Well the magneto-Seebeck effect can result in a positive or a negative potential, and it also changes with temperature. In fact there can be a crossover temperature where it changes from positive to negative. Hence the DC current flowing around the closed loop of iron wire could heat the thin zinc plates to take it through that crossover temperature, whereupon the current decreases, the zinc cools down then the whole process repeats itself. This would result in a very low frequency AC voltage being observed.

(57) **ABSTRACT**

Atmospheric Transduction System including a Power Frequency broadcast station, a receiver, and a network. The Power Frequency broadcast station includes a transmitter and a computer server. The receiver is in communication with the Power Frequency broadcast transmitter and also includes a user interface for receiving user input commands comprising a request for information from the Power Frequency broadcast station. The receiver is configured to establish a two-way communication path between the receiver and the Power Frequency broadcast transmitter. The network is in communication with the transducer, controller and the receiver for exchanging information therebetween. In response to oscillation translation and/or rotation of the electronic transducer, portions of forces induced by the mass are transferred to the piezoelectric elements. Electrical energy output by these piezoelectric elements is received in a power controller and can be applied to the battery as self charging. The piezoelectric transducer includes a conductive rotor and bearings, at least one of them incorporating a vibrator of mechanical oscillation, having a piezoelectric transducer converting mechanical vibrations into electric power.

ATMOSPHERIC TRANSDUCTION SYSTEM

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] NONE

BACKGROUND OF THE INVENTION

Field of the Invention

[0002] Self-propelled travel is a type of recreational adventure travel using human powered transport. This includes non-motorized machines such as a bicycle or skateboard. It is in contrast to traveling in a powered vehicle (such as an automobile) as in that case it is the vehicle which powers itself. Self-propelled travel is used to travel short distances or even for much longer distances such as bicycle touring. Self propelled describes something that moves, progresses or acts on its own power without needing outside help. Leonardo da Vinci's 1478 Self-Propelled Car: It was more than 500 years ago, however—sometime around the year 1478 to be more or less specific—when Leonardo drew out his plans for the world's first self-propelled vehicle. Experts originally believed two leaf springs, the simplest form of the spring typically used for automotive suspensions, somehow powered the vehicle. Closer inspection eventually revealed the power came from bigger, coiled springs located in tambours, cylindrical drum-like casings, inside the car's frame. The machine works like a robot or a wind-up toy simply by rotating the wheels opposite of their intended direction, which winds up the springs inside and gives it power. Self propulsion (of a vehicle) provided with its own source of tractive power rather than requiring an external means of propulsion.

[0003] In the middle of the 18th century, Benjamin Franklin's experiments showed that electrical phenomena of the atmosphere were not fundamentally different from those produced in the laboratory. By 1749, Franklin observed lightning to possess almost all the properties observable in electrical machines.

[0004] In July 1750, Franklin hypothesized that electricity could be taken from clouds via a tall metal aerial with a sharp point. Before Franklin could carry out his experiment, in 1752 Thomas-Francois Dalibard erected a 40-foot (12 m) iron rod at Marly-la-Ville, near Paris, drawing sparks from a passing cloud. With ground-insulated aerials, an experimenter could bring a grounded lead with an insulated wax handle close to the aerial, and observe a spark discharge from the aerial to the grounding wire. In May 1752, Dalibard affirmed that Franklin's theory was correct.

Piezoelectric Motor

[0005] A piezoelectric motor or piezo motor is a type of electric motor based upon the change in shape of a piezoelectric material when an electric field is applied. Piezoelectric motors make use of the converse piezoelectric effect whereby the material produces acoustic or ultrasonic vibrations in order to produce a linear or rotary motion. In one mechanism, the elongation in a single plane is used to make a series stretches and position holds, similar to the way a caterpillar moves. A transducer is a device that converts one form of energy to another. Energy types include (but are not limited to) electrical, mechanical, electromagnetic (including light), chemical, acoustic or thermal energy. While the term transducer commonly implies the use of a sensor/detector, any device which converts energy can be considered a transducer. Transducers are widely used in measuring instruments. Piezoelectric materials can also be used to harvest low levels of mechanical energy into electrical energy suitable for powering wireless sensors, low power microprocessors or charging batteries. Rotary Uses include rotating machines such as fans, turbines, drills, the wheels on electric cars, locomotives and conveyor belts. Also, in many vibrating or oscillating machines, an electric motor spins an unbalanced mass, causing the motor (and its mounting structure) to vibrate.

Atmospheric Electricity

[0006] There is always free electricity in the air and in the clouds, which acts by induction on the earth and electromagnetic devices. Experiments have shown that there is always free electricity in the atmosphere, which is sometimes negative and sometimes positive, but most generally positive, and the intensity of this free electricity is greater in the middle of the day than at morning or night and is greater in winter than in summer. In fine weather, the potential increases with altitude at about 30 volts per foot (100 V/m).

Atmospheric Layers

[0007] The electrical conductivity of the atmosphere increases exponentially with altitude. The amplitudes of the electric and magnetic components depend on season, latitude, and height above the sea level. The greater the altitude the more atmospheric electricity abounds. The exosphere is the uppermost layer of the atmosphere and is estimated to be 500 km to 1000 km above the Earth's surface, and its upper boundary at about 10,000 km. The thermosphere (upper atmosphere) is the layer of the Earth's atmosphere directly above the mesosphere and directly below the exosphere. Within this layer, ultraviolet radiation causes ionization. Theories that have been proposed to explain the phenomenon of the polar aurora, but it has been demonstrated by experiments that it is due to currents of positive electricity passing from the higher regions of the atmosphere to the earth.

[0008] The mesosphere (middle atmosphere) is the layer of the Earth's atmosphere that is directly above the stratosphere and directly below the thermosphere. The mesosphere is located about 50-80/85 km above Earth's surface. The stratosphere (middle atmosphere) is a layer of Earth's atmosphere that is stratified in temperature and is situated between about 10 km and 50 km altitude above the surface at moderate latitudes, while at the poles it starts at about 8 km altitude. The stratosphere sits directly above the troposphere and directly below the mesosphere. The troposphere (lower atmosphere) is the densest layer of the atmosphere.

[0009] The planetary boundary layer (PBL), also known as the atmospheric boundary layer (ABL), is the lowest part of the atmosphere and its behavior is directly influenced by its contact with the planetary surface. It is also known as the "exchange layer". (see also: p-n junction.)

[0010] There is a potential gradient at ground level ("Atmosphere ground layer") and this vertical field corresponds to the negative charge in and near the Earth's surface. The negative potential gradient falls rapidly as altitude increases from the ground. Most of this potential gradient is in the first few kilometers. The positive potential gradient rises rapidly as altitude increases from the ground. Volta, over two centuries before the 21st century, discovered with some degree of exactitude that the proportions of the ordinates of the curve or gradient of electric potential increased as the distance from the earth increases, and, more recently, Engel has provided data to calculate the increase (Image to the right).

Drum-Type Generator

[0011] A drum-type homopolar generator has a magnetic field (B) that radiates radially from the center of the drum and induces voltage (V) down the length of the drum. A conducting drum spun from above in the field of a "loudspeaker" type of magnet that has one pole in the center of the drum and the other pole surrounding the drum could use conducting ball bearings at the top and bottom of the drum to pick up the generated current.

Astrophysical Unipolar Inductors

[0012] Unipolar inductors occur in astrophysics where a conductor rotates through a magnetic field, for example, the movement of the highly conductive plasma in a cosmic body's ionosphere through its magnetic field. In their book, Cosmical Electrodynamics, Hannes Alfvén and Carl-Gunne Fälthammar write:

[0013] "Since cosmical clouds of ionized gas are generally magnetized, their motion produces induced electric fields [. . .] For example the motion of the magnetized interplanetary plasma produces electric fields that are essential for the production of aurora and magnetic storms" [. . .]

[0014] " . . . the rotation of a conductor in a magnetic field produces an electric field in the system at rest.

[0015] This phenomenon is well known from laboratory experiments and is usually called 'homopolar' or 'unipolar' induction.

The Faraday Disc

[0016] The homopolar generator was developed first by Michael Faraday during his experiments in 1831. It is frequently called the Faraday disc in his honor. It was the beginning of modern dynamos—that is, electrical generators which operate using a magnetic field. It was very inefficient and was not used as a practical power source, but it showed the possibility of generating electric power using magnetism, and led the way for commutated direct current dynamos and then alternating current alternators.

Boeing 737-800

[0017] The Boeing Fuel Cell Demonstrator Airplane has a Proton Exchange Membrane (PEM) fuel cell/lithium-ion battery hybrid system to power an electric motor, which is coupled to a conventional propeller. The fuel cell provides all power for the cruise phase of flight. During takeoff and climb, the flight segment that requires the most power, the system draws on lightweight lithium-ion batteries.

[0018] The demonstrator aircraft is a Dimona motor glider, built by Diamond Aircraft Industries of Austria, which also carried out structural modifications to the aircraft. With a wing span of 16.3 meters (53.5 feet), the airplane will be able to cruise at approximately 100 kilometers per hour (62 miles per hour) on power from the fuel cell.

[0019] Nikola Tesla explored the wireless transmission of energy through his work with radio and microwaves and his creation of the Tesla coil and the magnifying transmitter. In 1898, Tesla demonstrated his radio-controlled boat, which he was able to control remotely. In the 1930s, Tesla claimed to have invented a particle beam weapon, or, as some called it, a "peace ray." The device was, in theory, capable of generating an intense, targeted beam of energy and sending it across great distances to demolish warplanes, foreign armies, or anything else you'd rather didn't exist.

[0020] "Roy J. Meyers, British Patent Number 1098"

[0021] This invention relates to improvements in apparatus for the production of electrical currents, and the primary object in view is the production of a commercially serviceable electrical current without the employment of mechanical or chemical action. To this end the invention comprises means for producing what I believe to be dynamic electricity from the earth and its ambient elements.

[0022] Edward Leedskalnin: Magnetic Current—

[0023] The Perpetual Motion Holder is primarily a teaching device but it has many functions including an electromagnet, this is easy enough to see; it is a generator—spin a magnet between the coils it will generate electricity; it functions as a transformer; it demonstrates how permanent magnets are made, and is a holder of perpetual motion.

Strategic Defense Initiative

[0024] The Strategic Defense Initiative (SDI) was proposed to use ground and space-based systems to protect the United States from attack by strategic nuclear ballistic missiles.

Description of the Related Art

[0025] The present invention relates to a ball bearing assembly structure, an electromagnetic clutch having the ball bearing assembly structure, and a gas compressor equipped with the electromagnetic clutch.

[0026] When operating the gas compressor, the electromagnet of the electromagnetic clutch is energized to attract or adsorb the follower armature plate to an end surface of the prime-mover pulley and join the prime-mover pulley and the rotor shaft, thereby rotating the rotor shaft.

[0027] The ball bearing of the electromagnetic clutch conventionally has used one having an even number of balls per row. Generally, the ball bearing causes vibration and noise due to rotation. In the case of the ball bearing rotating while undergoing a radial load due to a tension of the belt, vibration and noise considerably occur. Particularly when other vibration and noise levels are lowered during engine idling, the vibration and noise of the ball bearing transmitted to the vehicular compartment is not negligible.

[0028] The inventor has conducted various experiments and discovered that the one factor of high vibration and noise level is an even number of balls of the ball bearing. In the ball bearing having an even number of balls per one row, the balls are in a facing relation to have linear-symmetry arrangement between the inner race and the outer race. The deformation and vibration at a regular particular frequency is caused in the inner and outer races. It is to be considered that the vibration as a source also increases noise.

[0029] The present invention relates generally and in various embodiments to piezoelectric mechanical systems. More specifically, the present invention relates generally and in various embodiments to atmospheric oscillation transducer apparatuses, systems, and methods.

[0030] Although various implementations of the present invention, among many, may be described herein with reference to the specific illustrative embodiments related to particular applications, those skilled in the art will understand that the invention is not in any way intended to be limited to such embodiments and/or applications. Those having ordinary skill in the art and reference to the description of the embodiments herein will recognize additional modifications, applications, and other embodiments falling within the scope of the claimed invention and additional fields in which the present invention may be practiced.

[0031] Digital Radio (also known as Satellite Radio or Satellite Digital Audio Radio Service (SDARS)) is a subscriber-based digital radio service that is broadcast via satellites. Digital radio service provides compact-disc (CD) quality programming that may be digitally transmitted via one or more satellites and/or space stations to one or more Earth-based (terrestrial) digital radio stations, receivers, and/or repeaters. In satellite-based direct-broadcast radio services, digitally-encoded audio program material may be broadcast to terrestrial fixed or mobile digital radio receivers. Fixed receivers may include, for example, stand alone digital radio receivers or digital radio receivers connected via computer networks, including for example, the Internet. Mobile receivers may include, for example, digital radio receivers located in automobiles, aircrafts, watercrafts, and the like.

[0032] Satellite-based digital audio radio services such as SDARS, for example, may be broadcast to one or more digital radio receivers either directly from an orbiting satellite, or indirectly from one or more repeater stations. Such repeater stations may be useful where the digital radio receiver is located in a shielded location or where there is no direct line of sight between the radio and the satellite. In other digital audio radio services systems, the audio programs also may be transmitted in digital form by one or more space stations directly to fixed, mobile, and/or portable radio stations. Such systems may comprise, for example, orbiting satellites, complementary repeating terrestrial transmitters, telemetry, tracking, and control facilities.

[0033] Combinations of mechanical devices U.S. Pat. Nos. 4,019,073, 6,615,968 and atmospheric system interaction are disclosed in U.S. Pat. Nos. 1,119,732, 787,412, 6,902,513 to Nikola Tesla; 28,793 to Charles Vion; and U.S. Pat. No. 1,540,998 to Herman Plauson. Lastly, U.S. Pat. No. 8,102,078 and US2008/0009240. Agnoff discloses an Oscillating watch winder in U.S. Pat. No. 6,543,929, Jennings further discloses an oscillating smart device in application No. 13,572,679.

[0034] As illustrated by a large body of prior art, including the above-noted patents, and a large number of commercial devices, efforts are continuously being made in an attempt to improve helmets, headsets and their methods of fabrication. Nothing in the prior art, however, suggests the present inventive combination of materials and method steps as herein described and claimed. The present invention achieves its purposes, objects and advantages over the prior art through a new, useful and unobvious combination of components and method steps which improve safety, comfort and noise abatement performance.

[0035] Therefore, it is an object of this invention to provide Effectively, the provision of energy such that it meets the needs of the present without compromising the ability of future generations to meet their own needs . . . . Sustainable Energy has two key components: renewable energy and energy efficiency.

[0036] It is still a further objection of this invention to promote Dynamic harmony between equitable availability of energy-intensive goods and services to all people and the preservation of the earth for future generations." And, "the solution will lie in finding sustainable energy sources and more efficient means of converting and utilizing energy.

[0037] It is a further object of the present invention to produce Green Power Energy: is energy that can be extracted, generated, and/or consumed without any significant negative impact to the environment, green power; as electricity produced from solar, wind, geothermal, biogas, biomass, and low-impact small hydroelectric sources.

[0038] Thus, there is a need for a clean energy system that uses atmospheric electricity.

Prior Art

[0039] Quartz crystals have been in regular use for many years to give an accurate frequency for all radio transmitters, radio receivers and computers. Their accuracy comes from an amazing set of coincidences: Quartz—which is silicon dioxide like most sand—is unaffected by most solvents and remains crystalline to hundreds of degrees Fahrenheit. The property that makes it an electronic miracle is the fact that, when compressed or bent, it generates a charge or voltage on its surface. This is a fairly common phenomenon called the Piezoelectric effect. In the same way, if a voltage is applied, quartz will bend or change its shape very slightly.

[0040] If a bell were shaped by grinding a single crystal of quartz, it would ring for minutes after being tapped. Almost no energy is lost in the material. A quartz bell—if shaped in the right direction to the crystalline axis—will have an oscillating voltage on its surface, and the rate of oscillation is unaffected by temperature. If the surface voltage on the crystal is picked off with plated electrodes and amplified by a transistor or integrated circuit, it can be re-applied to the bell to keep it ringing.

[0041] The electronics of the watch initially amplifies noise at the crystal frequency. This builds or regenerates into oscillation—it starts the crystal ringing. The output of the watch crystal oscillator is then converted to pulses suitable for the digital circuits.

Polymers

[0042] Polyvinylidene fluoride (PVDF): PVDF exhibits piezoelectricity several times greater than quartz. Unlike ceramics, where the crystal structure of the material creates the piezoelectric effect, in polymers the intertwined long-chain molecules attract and repel each other when an electric field is applied.

Near Space

[0043] Solar particles become trapped within the Earth's magnetic field and form radiation belts. The Van Allen radiation belt is a torus of energetic charged particles (i.e. a plasma) around Earth, trapped by Earth's magnetic field.

[0044] At elevations above the clouds, atmospheric electricity forms a continuous and distinct element (called the electrosphere) in which the Earth is surrounded. The electrosphere layer (from tens of kilometers above the surface of the earth to the ionosphere) has a high electrical conductivity and is essentially at a constant electric potential. The ionosphere is the inner edge of the magnetosphere and is the part of the atmosphere that is ionized by solar radiation. (Photoionisation is a physical process in which a photon is incident on an atom, ion or molecule, resulting in the ejection of one or more electrons.)

Advantages/Disadvantages

[0045] Energy in electronic elements: Electric potential energy, or electrostatic potential energy, is a potential energy (measured in joules) that results from conservative Coulomb forces and is associated with the configuration of a particular set of point charges within a defined system. The term "electric potential energy" is used to describe the potential energy in systems with time-variant electric fields, while the term "electrostatic potential energy" is used to describe the potential energy in systems with time-invariant electric fields.

[0046] Capacitance is the ability of a body to store an electrical charge. Any body or structure that is capable of being charged, either with static electricity or by an electric current, exhibits capacitance. A common form of energy storage device is a parallel-plate capacitor. In a parallel plate capacitor, capacitance is directly proportional to the surface area of the conductor plates and inversely proportional to the separation distance between the plates. If the charges on the plates are +q and −q, and V gives the voltage between the plates, then the capacitance C is given by

$$C=q/V.$$

[0047] The capacitance is a function only of the physical dimensions (geometry) of the conductors and the permittivity of the dielectric. It is independent of the potential difference between the conductors and the total charge on them.

[0048] Piezoelectricity is the combined effect of the electrical behavior of the material:

$$D=\in E$$

where D is the electric charge density displacement (electric displacement), $\in$ is permittivity and E is electric field strength, and

$$\text{Hooke's Law: } S=sT$$

where S is strain, s is compliance and T is stress.

[0049] Polyvinylidene fluoride, or polyvinylidene difluoride (PVDF) is a highly non-reactive and pure thermoplastic fluoropolymer produced by the polymerization of vinylidene difluoride. PVDF is a specialty plastic material in the fluoropolymer family; it is used generally in applications requiring the highest purity, strength, and resistance to solvents, acids, bases and heat and low smoke generation during a fire event. Compared to other fluoropolymers, it has an easier melt process because of its relatively low melting point of around 177° C.

[0050] It has a low density (1.78) and low cost compared to the other fluoropolymers. It is available as piping products, sheet, tubing, films, plate and an insulator for premium wire. It can be injected, molded or welded and is commonly used in the chemical, semiconductor, medical and defense industries, as well as in lithium ion batteries. It is also available as a crosslinked closed cell foam, used increasingly in aviation and aerospace. PVDF has a glass transition temperature (Tg) of about −35° C. and is typically 50-60% crystalline. To give the material its piezoelectric properties, it is mechanically stretched to orient the molecular chains and then poled under tension. PVDF exists in several forms: alpha (TGTG'), beta (TTTT), and gamma (TTTGTTTG') phases, depending on the chain conformations as trans (T) or gauche (G) linkages. When poled, PVDF is a ferroelectric polymer, exhibiting efficient piezoelectric and pyroelectric properties. These characteristics make it useful in sensor and battery applications. Thin films of PVDF are used in some newer thermal camera sensors.

[0051] Copolymers: Copolymers of PVDF are also used in piezoelectric and electrostrictive applications. One of the most commonly-used copolymers is P(VDF-trifluoroethylene), usually available in ratios of about 50:50 wt % and 65:35 wt % (equivalent to about 56:44 mol % and 70:30 mol %). Another one is P(VDF-tetrafluoroethylene). They improve the piezoelectric response by improving the crystallinity of the material.

[0052] While the copolymers' unit structures are less polar than that of pure PVDF, the copolymers typically have a much higher crystallinity. This results in a larger piezoelectric response: d33 values for P(VDF-TrFE) have been recorded to be as high as −38 pC/N versus −33 pC/N in pure PVDF.

[0053] Applications:

[0054] The piezoelectric properties of PVDF are used to advantage to manufacture tactile sensor arrays, inexpensive strain gauges and lightweight audio transducers. Piezoelectric panels made of PVDF are used on the Venetia Burney Student Dust Counter, a scientific instrument of the New Horizons space probe that measures dust density in the outer solar system. PVDF is the standard binder material used in the production of composite electrodes for lithium ion batteries. 1-2% weight solution of PVDF dissolved in N-Methyl-2-pyrrolidone (NMP) is mixed with an active lithium storage material such as graphite, silicon, tin, $LiCoO2$, $LiMn2O4$, or $LiFePO4$ and a conductive additive such as carbon black or carbon nanofibers. This slurry is cast onto a metallic current collector and the NMP is evaporated to form a composite or paste electrode. PVDF is used because it is chemically inert over the potential range used and does not react with the electrolyte or lithium. Piezoelectric elements can be used in laser mirror alignment, where their ability to move a large mass (the mirror mount) over microscopic distances is exploited to electronically align some laser mirrors. By precisely controlling the distance between mirrors, the laser electronics can accurately maintain optical conditions inside the laser cavity to optimize the beam output. Piezoelectric sensors especially are used with high frequency sound in ultrasonic transducers for medical imaging and also industrial nondestructive testing (NDT).

[0055] For many sensing techniques, the sensor can act as both a sensor and an actuator—often the term transducer is preferred when the device acts in this dual capacity, but most piezo devices have this property of reversibility whether it is used or not. Ultrasonic transducers, for example, can inject ultrasound waves into the body, receive the returned wave, and convert it to an electrical signal (a voltage). Most medical ultrasound transducers are piezoelectric.

[0056] Advantageously,

[0057] Sustainable energy is the sustainable provision of energy that meets the needs of the present without compromising the ability of future generations to meet their needs. Technologies that promote sustainable energy include renewable energy sources, such as hydroelectricity, solar energy, wind energy, wave power, geothermal energy, and tidal power, and also technologies designed to improve energy efficiency.

[0058] This sequence of oscillations causes the rotor within the watch to spin rapidly thereby winding the watch in a manner closely simulating the spinning of the rotor that occurs during normal winding of the watch when the watch is worn by a user. Due to the forces that are exerted, the rotor spins around the watch shaft during the oscillations, as opposed to the partial rotation observed in prior art mechanisms. Therefore, the time required to wind the watch, and the energy required, is substantially reduced. Moreover, since the rotor is spinning about the shaft, as opposed to merely being held in a downward position while the watch is rotated, winding more closely approximating the design mechanism is achieved, thereby putting less wear on the watch.

[0059] This invention relates to satellite communications systems using multiple spot beams from a geosynchronous earth orbit satellite to provide selective coverage of the continental United States and, more particularly, relates to a system having a satellite receiving hub in every spot beam that allows for asynchronous communications between each hub and the satellite for maximizing frequency re-use.

[0060] These purposes, objects and advantages should be construed as merely illustrative of some of the more prominent features and applications of the present invention. Many other beneficial results can be obtained by applying the disclosed invention in a different manner or by modifying the invention within the scope of the disclosure. Accordingly, other purposes, objects and advantages as well as a fuller understanding of the invention may be had by referring to the summary herein mentioned and detailed description describing the preferred embodiments of the invention, in addition to the scope of the invention, as defined by the claims, taken in conjunction with the accompanying drawings.

SUMMARY OF THE INVENTION

[0061] In one general respect, an embodiment of the present invention is directed to a system. The system includes a Power Frequency broadcast station, a receiver, and a network. The Power Frequency broadcast station includes a transmitter and a server. The receiver is in communication with the Power Frequency broadcast transmitter and also includes a user interface for receiving user input commands comprising a request for information from the Power Frequency broadcast station.

[0062] The receiver is configured to establish a two-way communication path between the receiver and the Power Frequency broadcast transmitter. The network is in communication with the server and the receiver for exchanging information therebetween. The request for information is provided to the server via the network and the server is configured to receive the request and transmit a response message to the receiver in accordance with the request.

Continuously Outboard Recharged Electric Vehicle (COREY)

[0063] Given suitable infrastructure, permissions and vehicles, BEVs (battery electric vehicles) can be recharged while the user drives. The BEV establishes contact with an electrified rail, plate or overhead wires on the highway via an attached conducting wheel or other similar mechanism (see Conduit current collection). The BEV's batteries are recharged by this process—on the highway—and can then be used normally on other roads until the battery is discharged. Some of battery-electric locomotives used for maintenance trains on the London Underground are capable of this mode of operation. Power is picked up from the electrified rails where possible, switching to battery power where the electricity supply is disconnected.

[0064] The present invention is directed to overcome the disadvantages of the prior art. The invention is a mechanism which taps into the naturally occurring static electricity in the atmosphere. Whereas heretofore, the attempt to garner electricity from the atmosphere has focused exclusively on capturing lightning, the present invention syphons off the static electricity which is generated from any agitated air and voids lightning.

[0065] Lightning is only the final discharge of the static electricity, whether that lightning is intra-cloud lightning, cloud-to-ground lightning, or inter-cloud lightning. Other types of final discharges are known as heat lightning, summer lightning, sheet lightning, ribbon lightning, silent lightning, ball lightning, bead lightning, elves, jets, and sprites. Well before these discharges are observed, as the atmosphere becomes agitated by wind or thermal, static electricity is being generated. The present invention recognizes that this static electricity is being formed and creates a mechanism to capture it.

[0066] In the preferred embodiment, a sensor array is used to monitor the activities both at the base unit (such as electrical flow within the conductor) and in the surrounding locale. A sensor monitoring the electrical flow (i.e. voltage and/or current) within the conductor is used to monitor the electrical activity within the conductor.

[0067] In the preferred embodiment, a lightning sensor monitors for lightning activity within the locale. As noted earlier, the electrical characteristic of lightning is so extreme that ideally this discharge is avoided as it might damage the mechanism of this invention. The sensor array is utilized by a controller, such as microprocessor, programmed to operate the mechanism as outlined herein.

[0068] The controller operates the winch motor to extend or withdraw the conductive line and by extension the altitude of the balloon. The controller is programmed to operate the winch by monitoring the electrical characteristics of the conductor and adjusting the balloon's altitude to maintain these characteristics within the conductor within a preset range.

[0069] This preset range is established either in the base programming of the controller or is established by an operator of the system. As example, by controlling the amount of current being withdrawn from the atmosphere, the mechanism operates within a safe range and also provides a relatively stable current flow from which a variety of activities can take place (such as DC-AC conversion).

[0070] The controller also utilizes the lightning sensor to protect the mechanism from a lightning strike. Should lightning be detected within a pre-determined range (as established by the software or defined by an operator), then the balloon is pulled down to minimize the risk of damage from a lightning strike.

[0071] Another aspect of the invention relates to the electrical system which accepts the fluctuating atmospheric charge and changes it into an acceptable configuration for either the desired load or for the existing power grid.

[0072] Power grids in the United States operate with a frequency of 60 hertz in an alternating current arrangement. While this basic configuration seems to be universally accepted, the voltage within the grid varies dramatically, such as 15 kv, 34 kv, 69 kv, and even 112 kv.

[0073] Each atmospheric generator is placed proximate to or within easy access to a specific grid; this establishes the required electrical output configuration (i.e. that which is accepted by the power grid). As example, one of the atmospheric electrical collector units as described above collects the atmospheric electrical power as direct current and then supplies the appropriate power grid a specific flow (as example, AC, 60 hertz, at 69 kv).

[0074] The difficulty lies the fact that the DC current being garnered from the atmosphere varies depending on the actual agitation being generated in the atmosphere. This means that the source of DC current is fluctuating.

[0075] The present invention uses a monitoring system which checks the input DC voltage. Depending on the actual voltage being received, the appropriate converter is connected to the input DC voltage so that the desired output is obtained.

[0076] As example, suppose the DC input voltage is 1500 volts, the monitoring system, sensing this input, closes the switch connecting the DC voltage to a converter which accepts DC voltage in the range of 1000-2000 volts which then delivers an AC, 60 hertz 69 kv signal to the power grid. If the DC input voltage increases to 2100 volts, then the monitoring system opens the switch to the first converter (1000-2000 volts) and closes the switch to a second converter (such as 2000-4000 volts) to deliver the desired output of AC (60 hertz, 69 kv) for the power grid.

[0077] In this manner, regardless of the fluctuating input DC voltage, the electrical grid is supplied with a fully configured electrical input conforming to the needs of that specific electrical grid.

[0078] Another aspect of the present invention is the use of a tower or permanent structure instead of an aircraft. In this embodiment, the building or tower is electrically isolated from the ground and a rod (similar to a lightning rod) is extended into the atmosphere. The rod collects the atmospheric charge which is conveyed via an electrical conduit (ideally insulated) where the collected DC charge is reconfigured to meets the need of the locale.

[0079] In this context, for one embodiment of the invention, a tower is placed onto the top of a building. The tower is electrically isolated from the building using such mechanisms well known to those of ordinary skill in the art such as rubber mats. A rod ideally extends from the top of the tower to facilitate the collection of the DC electrical energy.

[0080] Piezoelectricity is a material property that is manifested when voltage is produced by applying mechanical forces, and vice versa, the effect has been described as direct and converse. Piezoelectricity has been described as coupling between a quasi-static electric field and dynamic mechanical motion.

[0081] A piezoelectricity converter mechanism such as described above, is connected to the tower to flow the DC electricity to a converter which modifies the DC current for the specific application. In one application, the DC current is converted to the electrical needs of the building, thereby providing at least some of the electrical requirements of the building itself.

[0082] As noted earlier, the dynamic converter system of the present invention allows a power generator to address a variable voltage in an efficient manner. This makes the dynamic converter system ideal for a variety of alternative energy sources such as the above described atmospheric electrical generator and other alternative energy sources such as wind and wave powered systems. In these systems, the energy being generated must be converted to a proper electrical configuration for a identified load. This may be a particular motor or connection to the power grid which act as a load to the power generating mechanism.

[0083] For these energy generating systems, the converter assembly of this invention utilizes multiple converters. Each converter is configured to accept a unique range of voltages and from these voltages, create the desired electrical configuration. By using multiple converters, a full range is available, from a minimum voltage input to a maximum voltage input.

[0084] The present invention can include systems and methods for integrating sensors for tracking atmospheric transducer system performance metrics into media devices and accessories therefor, thereby reducing or eliminating the need for additional independent monitoring devices. In one embodiment of the present invention.

[0085] It also is known to provide such transducers with connectors to allow their rechargeable batteries to be charged. In some cases, the connector is a Universal Serial Bus (USB) connector, allowing the transducer to be charged by plugging it into the USB port of a computer, grid circuit or other device.

[0086] These and other objects and advantages of the invention will appear more clearly from the following description in which the preferred embodiment of the invention has been set forth in conjunction with the drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

[0087] FIG. **1** Prior Art depicts perspective view of Electric currents created in sunward ionosphere;

[0088] FIG. **2** is a box flow chart of the propulsion cycle systems present invention;

[0089] FIG. **3** is an top view of the piezoelectric disk cylinder orb of the present invention;

[0090] FIG. **4** is a longitudinal sectional view showing an embodiment of this invention;

[0091] FIG. **5** is a top view of the (ATS) slip rotor piezoelectric chamber of the present invention;

[0092] FIG. **6** is an alternate top view of the piezoelectric cylinder orb of the present invention;

[0093] FIG. **7-10** elevation views of spine piezo stacks embodiments of the present invention;

[0094] FIG. **11** illustrates one embodiment of a power service (ATS) system architecture;

[0095] FIG. **12** is a block diagram of the ATS charge schematics systems of the present invention;

[0096] FIG. **13** is a block diagram of an ATS charge and recycle schematics of the present invention;

[0097] FIG. **14** is a view of the piezoelectric ball race cylinder of the present invention;

[0098] FIG. **15** is a view of the piezoelectric housing and gear of the present invention;

[0099] FIG. **16** is a view of a multiple piezoelectric ball race cylinder of the present invention;

[0100] FIG. **17** is another embodiment of the piezoelectric stack ball of the present invention;

[0101] FIGS. **18** & **19** are antenna rod transmit device embodiments of the (ATS) present invention;

[0102] FIG. **20** illustrates substation embodiment of the power service (ATS) system architecture;

[0103] FIG. **21** illustrates a home embodiment of the power service (ATS) system architecture;

[0104] FIG. **22** illustrates a window embodiment of the power service (ATS) system architecture;

[0105] FIG. **23** is (ATS) shock device in accordance with an embodiment of the present invention;

[0106] FIG. **24** is (ATS) shock device in accordance with an embodiment of the present invention;

[0107] FIG. **25** is (ATS) motorcycle device embodiment of the present invention;

[0108] FIG. **26** is (ATS) axle device in accordance with an embodiment of the present invention;

[0109] FIG. **27** is (ATS) train device in accordance with an embodiment of the present invention;

[0110] FIG. **28** is (ATS) plane device in accordance with an embodiment of the present invention;

[0111] FIG. **29** is (ATS) boat device in accordance with an embodiment of the present invention;

[0112] FIG. **30** is (ATS) solar device in accordance with an embodiment of the present invention;

[0113] FIG. **31** a (ATS) turbine device in accordance with an embodiment of the present invention;

[0114] FIG. **32** is (ATS) auto body panel device embodiment of the present invention;

[0115] FIG. **33** is (ATS) motorcycle body fairing panel device in of the present invention; and

[0116] FIG. **34** is (ATS) cross section view of body embed panel device of the present invention.

DETAILED DESCRIPTION

[0117] This sequence of oscillations causes the conductive rotor within piezoelectric molded housing device to spin rapidly thereby winding the mechanism in a manner closely simulating the spinning of the conductive rotor that occurs during normal electric activity when the device is activated. Due to the forces that are exerted, the conductive rotor spins around the piezoelectric cylinder device shaft during the oscillations, as opposed to the partial rotation observed in prior art mechanisms. Therefore, the time required to charge the Atmospheric Transduction System (ATS) device, and the energy required, is substantially reduced. Moreover, since the rotor is spinning about the shaft, as opposed to merely being held in a downward position while the ATS device is rotated, recharging more closely approximating the design mechanism is achieved, thereby putting less wear on the ATS chamber device Innovative Piezoelectric housing and ball bearing, coupler and book spine stacks. There relies the notion of negative ground electricity and positive aerial electricity which is in abundance. This invention substantiates land vehicles recycle recharge by reverse oscillation. Aerial vehicles recycle recharge by forward oscillation in accumulation of environmental positive and negative electricity. These aforementioned activities are integral or synchronous with frequency.

[0118] Prior Art FIG. **1**

[0119] Electric currents created in sunward ionosphere. FIG. **2** is a recycle box flow chart **49** of a self propulsion unit consisting of a battery **27**, engine **29** and piezoelectric transducer **33** unit. FIG. **3** is a multiple disk **31** load part **51** about a 360 degree cylinder **45** and shaft **44**. FIG. **4** is a piezoelectric molded device **100** housing **110** containing a ball bearing race **104**, disk stacks capacitor **102** and conductive rotor **46**. FIG. **5** is a piezoelectric chamber **120** configuration including a counterweights **50**, shaft **44**, conductive slip rotor **106**. FIG. **6** is an alternate part **200** chamber cylinder **201** embodiment containing piezoelectric spine disk stack capacitors **102**. FIG. **7-10** are variations of spine **107**,**108**,**109**,**110** case piezoelectric stack capacitor **102** with plate and ball heads. FIG. **11** Various embodiments of the present invention, among others, will now be described with reference to the accompanying drawings. Accordingly, FIG. **11** illustrates an embodiment of a Atmospheric Transduction (ATS) System **300** architecture. The system **300** may include, for example, a satellite broadcast station **318** that transmits signals **333** containing frequency content from a geostationary satellite **312** by way of airplane antenna **326**. In turn, the satellite **312** transmits line-of-sight (LOS) signals **333** to one or more ATS terrestrial frequency power receiver farms **314**. The system **300** also may include one or more terrestrial repeaters **316** which receive and retransmit the satellite signals **333** as repeater signals **323** to facilitate reliable reception in geographic areas where LOS reception from the satellite **312** is obstructed by tall buildings, hills, tunnels, and other similar impediments to the signals **333**. The ATS receivers **314** maybe designed to receive one or more signals **333** from the satellite **312** and/or from the terrestrial repeater transceiver **316**. In operation, such ATS receivers **314** may receive both the satellite signals **333** and the repeater signals **323**. The receivers **314** also may be located in mobile environments **320**, **321**, **322** which include, but are not limited to, land vehicles **321**, **322**, aircraft **320**, watercraft **900**, and handheld devices, among others. The receivers **314** also may be fixed in stationary units for residential use (e.g., home **325**,**750** entertainment, etc.) or commercial **314**, **328**,**360** use (e.g., business **314**, office **700**, security **328**, etc.). The power frequency broadcast station **318** also may be in communication with a grid network **342**. Two-way communication between the ATS receivers **314** and the power frequency broadcast station **318** may occur via the network **342**. Furthermore, information feedback from the power frequency broadcast station **318** may be transmitted to the ATS receiver **314** both by way of the network **342** as well as via the satellite **312**. Information also may be transmitted to the power broadcast station **318** wirelessly via a wireless network **342**,**707** by way of transducer tower **360**.

[0120] Further disclosed in FIG. **12** and FIG. **13** (in block diagrams **400**, **500**) are electrical schematics for handling the static charge from the atmosphere. By maintaining the voltage being collected in a prescribed range, an electrical conversion system is easily designed. While FIGS. **12**, and **13** illustrate some electrical configurations, those of ordinary skill in the art readily recognize a variety of other configurations which will serve the same function.

[0121] Referencing FIG. **12**, Direct Current In (DC IN) **401** is buffered by a gang of capacitors **410** before being communicated to a DC/AC converter **420**. The DC/AC converter **420** converts the direct current into a an alternating current suitable for placement over an existing electrical grid **430** such as normally found from a power-plant. FIG. **12** Also illustrates an electrical arrangement suitable for use in charging a battery **440**. DC IN **401** is buffered by capacitor **410** bank before entering into a step down transformer **435**. Step down transformer **435** reduces the voltage so that the voltage can safely be introduced into battery **440** which is connected to ground **450** at the battery's other pole. In FIG. **12**, DC IN **401** is fed into an adjustable rheostat **460** which is controlled by the controller **465** so that the DC OUT **470** falls within a computer **475** monitored and sensor **480** specified range. FIG. **13** Hypothetically, unused energy may be recycled current **501** and/or recaptured by reversing the oscillated spin rotation of devices **51**, **100**, **120** with the use of a rectifier **502** and Step up transformer **503**, returned to grid **430** capacitor **410**. This theory lends itself to the concept of positive and negative frequency. FIG. **14-17** Self charging propulsion embodiment of the invention where Da Vinci's ball race **510**,**512** is combined with a disk cylinder **45** and **513** stack balls **525**, conductive rotor **46**, **511** tooth gear **515** and piezoelectric molded housing **555**. FIGS. **18** & **19** Improvement structures Franklin's lightening rod **600**,**603** and a molded vibration transducer **601** quasi replicating Vion's tubes and piezoelectric spine stacks capacitor **602** improving Tesla's Atmospheric transmit device. FIG. **20** is an atmospheric receiving building sub station **700** where energy is consumed and excess rendered to the grid **707** by conductive rotor **702** transducer **710**, tower transducer **703**, antenna rod **701** and transducer windows **704**.

[0122] FIG. **12** and FIG. **2** flowchart illustration also includes battery **440**. Battery **440** may provide electrical power to components of ATS devices within FIG. **11**. Charging circuitry may also be provided to charge battery **440** when an external power supply is connected to an ATS device **100**. FIG. **14-17** eliminates one or more steps by presenting a self charge retaining transducer **510-513** may be configured with an accelerator sensor **480** controller **465** and gears **515**, provide reciprocal power incorporated within piezoelectric molded and ceramic housing **555** along with stack balls **525** and cylinder **545**. This assembly more resembles a motor by characteristics given power with application.

[0123] In operation, as illustrated in FIGS. **2-20** and FIGS. **21-34**, is periodically energized by movement to rotate Orb in either a clockwise or counterclockwise direction. The length of time or activity is energized, and the length of time between the period when the capacitor **31**, **102** battery is energized, will depend on the particular ATS device design. As the Orb rotates, the outer end of the disk moves along a 360° circular pathway to push against with forward and rearwardly spinning. Upon engagement of the Orb, ATS device disk is rotated until carried to the apex or top of the circular pathway. Upon reaching the apex, the gravitational and vibrational force or counterweight **50** promotes additional oscillation. ATS device movement rapidly rotate on Orb at a rotational speed greater than the speed of rotation of Orb. Counterweight **50** is then carried beyond the bottom or lowest point of the pathway by its momentum to a point near the apex on the opposite side of the pathway. The cycle is repeated through multiple increasing oscillations of the ATS device until counterweight **50** stops at the bottom position, or until once again engages to again move counterweight to the top of its circular pathway.

[0124] FIG. **2** is a flow chart showing generation of energy using a rotor according to one or more of the above-described embodiments. First, battery **27** starts the engine **29** and/or mobile transducer **33** is oscillated. In response to this acceleration, forces are imposed on one or more rotation piezoelectric devices. In response to those forces, the piezoelectric devices output electrical energy, which energy is extracted at a power controller **465**. The power controller **465** sensor **480** then makes this energy available to recharge a capacitor **410** battery **440** and/or to electronic components of the mobile terminal. Although FIG. **2** shows a serial flow of events, it is to be appreciated that the events of blocks **33**, **27** and **29** occur substantially instantaneously upon acceleration of the mobile terminal.

Preferred Alternate Embodiments

[0125] The present invention (ATS) device in accordance with an embodiment of the present invention overcomes the foregoing problem in the conventional art and provides an electro energy vibration and alternative to gas, oil or fossil fuel consumption in FIG. **21** homes **750** transducer **755**, FIG. **28** airplane **880** transducer **801**, FIG. **27** train **860** transducer **801**, FIG. **32** auto **950** transducer **910**, FIG. **25** and FIG. **33** motorcycles **960**,**850** transducers **799**, **802**, **810**, **910** and FIG. **29** boat **900** transducers **901**,**910**.

[0126] In order to solve the foregoing problems in the conventional art, the present invention provides an electro transducer having a ball bearing assembly which is compatible with FIG. **26** axle shaft **44** transducer **810** wheel **870** assembly. In order to solve the foregoing problems in the conventional art, the present invention provides an electro transducer having an FIG. **34** housing panel **980** transducer **910** assembly which is compatible with an exterior body assembly. Thereby, an Atmospheric transducer device may be shock **800** integrated as within the FIG. **23** coupler **802**, and FIG. **24** ladder **799**, (vertical friction) piezoelectric absorbers assemblies. In order to solve the foregoing problems in the conventional art, the present invention provides an electro transducer having a capable flat assembly which is compatible with FIG. **22** window **704** disk **31** plate transducer **714**, FIG. **30** solar panel **920** transducer **910**, FIG. **31** wind turbine **930** transducer **910** assembly. This invention provided FIG. **3** piezoelectric plate disks **31**, FIG. **7-10** spine piezoelectric disks stacks **107-110** capacitor **102**, FIG. **17** piezoelectric stack balls **525** capacitor, the arrangement of balls **525** will not be in a facing relation. The deformation in the inner and outer races during rotation of the ball bearing while undergoing a radial load is made irregular and complicated. The spine eliminates the deformation and vibration level increased by a combination of ceramic and molded piezoelectric materials at a regular predetermined frequency thereby multiplying the level of vibration and noise reduction.

[0127] Certain modifications and improvements will occur to those skilled in the art upon a reading of the foregoing description. It should be understood that all such modifications and improvements have been deleted herein for the sake of conciseness and readability but are properly within the scope of the following claims.

[0128] Thus it is seen that an atmospheric transducer device may be integrated and/or provided. It will be understood that the foregoing is only illustrative of the principles of the invention, and that various modifications can be made by those skilled in the art without departing from the scope and spirit of the invention, and the present invention is limited only by the claims that follow.

1-3. (canceled)

4. An atmospheric transduction system comprising:

means for recycle recharge by oscillation and frequency in accumulation of environmental positive and negative electricity, maintaining the voltage being collected in a prescribed range, providing an electrical conversion broadcast network; and

means for collecting the atmospheric electrical power as direct current and then supplies the appropriate power grid, transceiver and capacitates a charge; and

means for self charging propulsion provides motor characteristics, and frequency engine.

5. The atmospheric transduction system in accordance with claim **1**, wherein said means for recycle recharge by oscillation and frequency in accumulation of environmental positive and negative electricity, maintaining the voltage being collected in a prescribed range, an electrical conversion broadcast network comprises piezoelectric transducer molded device(s), rotor, stack ball bearing, coupler, book spine stacks and antenna rod stacks;

wherein said means for collecting the atmospheric electrical power as direct current and then supplies the appropriate power grid and capacitates a charge comprises a piezoelectric network, piezoelectric grid, piezoelectric spine stack antenna, piezoelectric transmitters, piezoelectric receivers, piezoelectric devices, piezoelectric cylinders and orbs, power frequency broadcast;

wherein said means for charging providing motor characteristics, said power frequency engine comprises a sensor accelerator, rotor/gear, battery/capacitor, antenna, controller, for propulsion.

6. An atmospheric transduction system comprising:

a piezoelectric transducer molded device(s), rotor, spine ball bearing, coupler and book spine stack transducers, for recycle recharge by oscillation and frequency in accumulation of environmental positive and negative electricity, maintaining the voltage being collected in a prescribed range, providing an electrical conversion broadcast server network; and

a piezoelectric network, piezoelectric grid, piezoelectric spine stack antenna, piezoelectric transmitters, piezoelectric receivers, piezoelectric devices, piezoelectric cylinders and disc orbs, stack rods, power frequency broadcast, for collecting the atmospheric electrical power as direct current and then supplies the appropriate power grid, transceiver and capacitates a charge; and

a sensor accelerator, rotor/gear, battery/capacitor, controller, antenna, means for self charge propulsion providing motor characteristics, thereby an engine of power frequency.

UNITED STATES PATENT OFFICE

CLEMENT F. STREET, OF GREENWICH, CONNECTICUT, ASSIGNOR TO AMERICAN STEEL FOUNDRIES, OF CHICAGO, ILLINOIS, A CORPORATION OF NEW JERSEY

GRATE ASSEMBLY

Application filed February 21, 1929. Serial No. 341,683.

This invention pertains to grates, and more particularly to the multiple grate assemblies used on locomotives.

Locomotive grates are usually of the rocking type and it is common practice to shake them at frequent intervals while the locomotive is running. This is required for the reason that the coal commonly used leaves a heavy ash and clinkers between the burning coal and the grates, and if this is not removed, it will retard the flow to the fire of the air required for combustion. But there is a wide variation in the character of the coal used on locomotives, and while some of it when burning leaves a heavy ash and clinkers, other leaves a very light ash and few clinkers, if any.

It is common practice to use a drop grate in combination with a set of rocking grates, and this drop grate is operated by means of a set of levers which are handled from the ground. They can therefore be used only when the locomotive is standing.

This drop grate is pivoted near one side and is very different in construction from either the non-rocking type or from the rocking type shown in the construction herewith, and should not be confused therewith.

Grates of this type when used in this service are subject to a high degree of heat on their upper surface while the lower parts are immersed in a continuous flow of cold air. The different parts are therefore subject to different amounts of expansion and contraction, and an object of this invention is to provide a construction in which this will not result in warping and distortion of the parts of the assembly.

Another object of this invention is to provide a grate assembly which is inexpensive to build and maintain and one which fulfills all requirements for economic operation and maintenance.

Still another object is to provide a grate bar assembly which permits rapid cleaning of the fire and changes of the grate bars.

Yet another object is to provide a grate bar assembly which resists distortion, is readily removable and is capable of rapid conversion to provide different drafts to accommodate different fuels.

A further object is to provide a grate assembly wherein the grate members are secured to their supports by a minimum of parts, yet one which is so constructed that the grate members will be effectively and securely kept in place.

Still a further object is to provide a grate assembly which offers substantially no resistance to expansion and contraction yet at the same time is fixedly supported and effectively resists warping and twisting.

Yet a further object is to provide a grate assembly wherein the securing members between parts are reduced to a minimum, and wherein the clearances are predetermined and arranged to permit ease of operation and assemblage.

With these and various other objects in view, the invention may consist of certain novel features of construction and operation, as will be more fully described and particularly pointed out in the specification, drawings and claims appended hereto.

In the drawings, which illustrate an embodiment of the device and wherein like reference characters are used to designate like parts—

Figure 1 is a top plan view, showing the supporting relation of the grate frame to one of the grate plate members;

Figure 2 is a side elevation, partly in section, of the assemblage illustrated in Figure 1, the position occupied by the grate member completing the assembly being indicated in dotted lines;

Figure 3 is an end elevation of the grate assembly, the same being taken from the end of the grate frame provided with the trunnion;

Figure 4 is a cross section of the grate frame assembly illustrated in Figure 2, showing the relation of the shaker arm to the remainder of the assembly;

Figure 5 is a side elevation, partly in section, of a modified form of grate assembly, the position occupied by the grate member completing the assembly being indicated in dotted lines;

Figure 6 is a side elevation, partly in section, of still another modified form of grate assembly;

Figure 7 is a cross sectional view of the grate assembly illustrated in Figure 6; and

Figure 8 is a fragmentary side elevation, partly in section, of a modified form of securing means provided on the plate grate of the modified assembly illustrated in Figure 5.

Referring first of all to the modification shown in Figures 1 to 4 inclusive, the supporting frame 15 of the grate assembly consists essentially of a single longitudinal rib 16 provided at one end thereof with a trunnion socket 17 and at the other end thereof with a horseshoe or U-shaped trunnion socket 18, each of said sockets being provided with outstanding lug members 19 provided for locking purposes in a manner to be later described. It will of course be understood that the frame may be of any length to accommodate any size or any number of plate grates, the embodiment illustrated being for an assembly including two of such plate grates 20. The supporting frame is provided with an enlarged portion 21 adjacent the center thereof, said portion having downwardly extending bosses 22, the said bosses being provided with apertures 23. The grate plates 20 may be either of the arcuate or flat type provided with suitably disposed apertures 24, said apertures being of a size and spacing for proper draft purposes.

The plates 20 adjacent their inner or inboard end are provided with downwardly extending lugs 25 adapted to straddle the rib 16 and the bosses 22, said lugs being provided with aligned apertures adapted to register with the aperture 23 for the reception of a locking pin 26 for securing said plate grate to the support. The lugs 25 merge into and are integral with the plate and also with a reinforcing rib 27 formed on the inner end of the plate, said rib merging into and being integral with longitudinal ribs 28 which in turn merge into and are integral with a rib 29 formed on the outer end of said plate. Ribs 28 are preferably made deeper adjacent their centers than at their ends for the purpose of preventing the plate from sagging as a result of service, and to prevent said ribs from bowing outwardly, a series of local cross-ribs 30 is provided which ribs are integral with said ribs and merge into the plate.

In service, it has been found that under heat the ends of the plate will go up or the center will go down, so in order to prevent either one or both of these movements, local ribs 31 are provided suitably spaced and preferably in between or in staggered position with respect to the ribs 30, said ribs contacting with the longitudinal rib 16 of the frame. The inner end of the plate of course is restrained from going up by the pin 26, and the outer end is restrained from going up by providing the depending flange 29 with inwardly extending hooks 32 adapted to have locking engagement with the lugs 19. The frame may be suitably apertured at any place along its length, shown adjacent the center thereof, and may be provided with a guiding boss 38 adapted to cooperate with a portion of the jaws 33 of the shaker arm 34 secured by means of a rivet or lock connection 35 to said frame.

The structure is assembled with sufficient lost motion between the parts to allow them to go together easily and of course the first effect of warping will be to take up this lost motion and bring all the parts firmly in contact. After this has occurred, any further movement will be resisted by the vertical strength of the frame. In assembling the parts of the device, it is only necessary to slip the hooks 32 into engagement with the lugs 19, dropping the plate into place whereby the lugs 25 straddle the frame and the apertures in lugs 25 register with the aperture 23 provided in the bosses 22 whereupon the locking member 26 may be put in place. The adjacent grate plate may likewise be put in place, there being sufficient clearance for the parts to permit their ready assemblage.

Referring now more particularly to the form of the device illustrated in Figure 5, the longitudinal frame 116 is provided with trunnions 117 at each end thereof and outwardly extending lugs 119 are formed on said frame adjacent said trunnions. The plate grates 120 may be of the same construction as has been already described with respect to grate plate 20, the transverse hook members 132 being provided for cooperation with the lugs 119 for locking one end of the plate grate in operative position. As before, the longitudinal member is provided with an enlarged portion 121 provided with bosses 122 having apertures 123 therein for the reception of locking members cooperating with the depending lugs 125 provided on the grate plates. The longitudinal frame member may be provided at convenient places along its length with apertures 135 and 136 having bosses 137 and 138 disposed adjacent thereto for cooperation with parts of the shaker arm 134 to maintain the same in substantially fixed position with respect to said frame members, said shaker arm being provided with jaws 133 having apertures therein adapted to receive the locking member 139.

In the modification illustrated in Figure 8, the frame member 116 is provided with a trunnion 117 and outwardly extending lugs 119. The grate plate 120 is suitably supported on said frame but is provided with longitudinally extending hooks 140 adapted to cooperate with the lugs 119 to maintain the outer end of the grate plate in its operative position with respect to said frame.

Referring now more particularly to the modification illustrated in Figures 6 and 7, the longitudinal frame member 216 is provided at one end with a trunnion socket 217 and at the other end with the U-shaped trunnion 218. The frame member 216 is deeper adjacent the center thereof as is the case in the modifications already described, and this member may also be of substantially truss formation, as illustrated in Figure 7, that is, it is provided with an enlarged rib or bulbous portion 316 provided along the lower edge thereof. Outwardly extending lugs 219 are provided adjacent the trunnions and are adapted to provide cooperating locking relation with the longitudinal hook members 240 provided on the plate grate 220. The grate plate is provided with reinforcing flanges, as before described, the inner flange thereof being provided with depending lugs 225 provided with aligned apertures adapted to cooperate with apertures 223 provided in the lugs 222 formed on the longitudinal supporting member 216. Bosses 241 may also be provided on the supporting member adjacent suitably spaced apertures 236, said apertures being for the reception of securing means passing through the upstanding jaws 233 of the shaker arm 234, the longitudinal frame member being further provided with bosses 238 cooperating with the shaker arms to maintain the same in fixed position with respect to said frame.

The operation and assemblage of the modified forms are substantially the same as has already been described with respect to the first modification, and it is to be understood that I do not wish to be limited by the exact embodiment of the device shown, which is merely by way of illustration and not limitation, as various and other forms of the device will of course be apparent to those skilled in the art without departing from the spirit of the invention or the scope of the claims.

I claim:

1. In a grate assembly, the combination of a support, a grate member secured thereto, said member having staggered reinforcements thereon, certain of said reinforcements having contacting relation to said support.

2. In a grate assembly, the combination of a support, a grate member secured thereto, said member having reinforcements disposed at the sides and center thereof, the reinforcements at the center being in staggered relation to the reinforcements at the sides, said center reinforcements having contacting relation to said support.

3. In a grate assembly, the combination of a support having securing means thereon, a grate member carried by said support and having securing means at each end thereof adapted to cooperate with said first named securing means for fastening said grate member to said support, and reinforcing ribs disposed on said grate member and contacting with said support to prevent distortion of said grate member.

4. In a grate assembly, the combination of a support having securing means thereon, a grate member carried by said support and having a marginal reinforcement thereon, securing means at each end of said member adapted to cooperate with said first named securing means for fastening said grate member to said support, reinforcing ribs disposed on said grate member and integral with said marginal reinforcement to prevent distortion of the latter, and center reinforcing ribs disposed on said grate member and contacting said support to prevent distortion of said grate member.

5. In a grate assembly, the combination of a support having securing means thereon, a grate member carried by said support and having a marginal reinforcement thereon, securing means at each end of said member, certain of said means being integral with said marginal reinforcement, said last named securing means being adapted to cooperate with securing means on the support for fastening said grate member to said support, and reinforcing ribs disposed on said grate member and integral with said marginal reinforcement to prevent distortion of the latter.

6. In a grate assembly, the combination of a support having securing means thereon, a grate member carried by said support and having securing means at each end thereof adapted to cooperate with the securing means on the support for fastening said grate member to said support, one of said securing means including members disposed transversely of said grate member, and reinforcing ribs disposed on said grate member and contacting said support to prevent distortion of said grate member.

7. In a grate assembly, the combination of a support having securing means thereon, a grate member carried by said support and having securing means at each end thereof adapted to cooperate with the securing means on the support for fastening said grate member to said support, reinforcing ribs disposed on said grate member and contacting said support to prevent distortion of said grate member, and bosses and fastening means on said support for cooperation with shaking means for moving said assembly.

8. As an article of manufacture, a plate grate having marginal flanges, reinforcing means on said grate and integral with certain of said flanges to prevent distortion of said flanges, and fastening means on said grate integral with other of said flanges, certain of said fastening means including facing hook members.

9. As an article of manufacture, a plate grate having marginal flanges, reinforcing means on said grate and integral with certain of said flanges to prevent distortion of said flanges, reinforcing means adjacent the longitudinal center line of said grate and in staggered relation to said first named reinforcing means, and fastening means on said grate integral with other of said flanges, certain of said fastening means including facing hook members.

Signed at Chicago, Illinois, this 14th day of February, 1929.

CLEMENT F. STREET.

Patents

Device for obtaining energy from the electric field of the atmosphere

Abstract

The invention relates to electrical engineering and is intended for uninterrupted power supply of autonomous electrical equipment, for example, automatic weather stations or space probes. The technical result of the invention is the uninterrupted generation of energy from the electric field of the atmosphere in the required quantity. The device is easy, lack of moving parts, the simplicity of structural elements and the convenience of their transportation. The device contains electrodes, a supporting structure and ionizers of atmospheric gas. The electrodes are spaced along the lines of force of the electric field. Surrounded by the atmosphere, the electrodes are located on a supporting structure. The outer surface of these electrodes is structurally combined with ionizers of atmospheric gas. The lower electrode is a grounding electrode. Between the electrodes, Distances along the lines of force of the atmospheric electric field include the load. In the absence of contact of the device with the planet, the outer surface of all atmosphere-surrounded electrodes is structurally combined with ionizers of atmospheric gas. Current-carrying parts of the device, which are under voltage, are electrically isolated from the supporting structure. 2 yl.

Claims (1)

1. A device for obtaining energy from the electric field of the atmosphere, including electrodes spaced along field lines, the lower of which is an earth electrode, a supporting structure with atmosphere-surrounded electrodes, ionizers of atmospheric gas structurally aligned with the outer surface of these electrodes, characterized in that between spaced apart field lines with electrodes, the load is switched on, in the absence of contact of the device with the planet, the outer surface of all atmosphere-surrounded electrodes about aligned with the ionization of atmospheric gas, the conductive portion of the device under voltage, electrically insulated from the supporting structure.

Description

The invention relates to electrical engineering and is intended for uninterrupted power supply of autonomous electrical equipment, for example automatic weather station or space probes on the Earth and other planets having an atmospheric electric field.

Known difficulties associated with the uninterrupted power supply of autonomous electrical equipment. Internal sources of energy (batteries, batteries, fuel cells) require periodic replacement, refueling or recharging, that is, manual, manual maintenance. External sources of energy (running water, wind, sunlight) require massive large structures, converters with moving parts and are not always available.

To solve the problem, we need a low-power, but reliable uninterrupted source of energy at any time and in any place. Taking into account the operating conditions of the autonomous electrical equipment, it must be lightweight, structurally simple and convenient for transportation to any distances.

There are known devices for the indirect generation of energy from the atmosphere by means of water wheels, turbines and other hydropower plants, as well as for direct energy production from the atmosphere by means of windmills, turbines and other windmills. In these devices, the energy of the atmosphere is converted into heat, work or electricity.

The continuity of the supply of energy generated with their help can not be ensured. It depends on the state of the atmosphere, climatic conditions and season. (Chaly G. Energy yesterday, today, tomorrow - Chisinau: Kartia Moldovenna, 1977. - 202 pp., Ill., Pp. 44-64,).

For the prototype a lightning rod is adopted, which is designed to neutralize the energy of the atmospheric electric field. The lightning rod contains a vertically oriented bearing structure that rises above the terrain, and electrodes spaced along field lines, connected by a current collector. At the top of the structure, there is an electrode surrounded by an atmosphere - a lightning receiver in the form of a massive metal rod. It can be combined with an ionizer of atmospheric gas. The lower electrode is a grounding electrode and provides electrical contact of the device with the planet's surface (VVBazutkin et al., High Voltage Engineering .- Moscow: Energoatomizdat, textbook for high schools, 1986. - 464 p., Ill., Pp. 219-220). The construction of the lightning rod does not include the payload.

The features of the prototype, which coincide with the essential features of the claimed invention, are as follows. The lightning conductor contains electrodes, a supporting structure and ionizers of atmospheric gas. The electrodes are spaced along the lines of force of the electric field. Surrounded by the atmosphere, the electrodes are located on a supporting structure. The outer surface of these electrodes is structurally combined with ionizers of atmospheric gas. The lower electrode is a grounding electrode.

The reasons for preventing the required technical result from the prototype are as follows. Lightning conductor ensures the flow through the atmosphere of electric current only in the form of a periodic spark discharge. The transit time of this current is unpredictable, and the magnitude is random and can not be adjusted. The lightning rod does not contain a payload. It is designed to work in an abnormally strong electric field and for the most part of time is uselessly idle. Lightning conductor does not work in places where there are no thunderclouds. The lightning rod does not work in the absence of contact with the planet. The live parts of the lightning rod do not have electrical insulation from the supporting structure.

The technical result is the uninterrupted reception of energy from the electric field of the atmosphere in the required quantity and the creation for this purpose of the claimed device.

The device is advantageous for its lightness, lack of moving parts, simplicity of necessary structural elements and convenience of their transportation. It is more reliable than all devices of autonomous power supply, including wind generators and solar panels, since the electric field of the atmosphere depends little on the time of the year, exists around the clock and is accessible anywhere in the world.

The technical result is achieved as follows. Between the electrodes spaced along the lines of force of the atmospheric electric field, a load is applied. In the absence of contact of the device with the planet, the outer surface of all atmosphere-surrounded electrodes is structurally combined with ionizers of atmospheric gas. Current-carrying parts of the device, which are under voltage, are electrically isolated from the supporting structure.

The essential features of the claimed invention are as follows. An apparatus for recovering energy from the atmospheric electric field comprises electrodes spaced along the electric field lines, the lower electrode is an earth electrode. The electrodes surrounded by the atmosphere are placed on a supporting structure. Ionizers of atmospheric gas are structurally combined with the outer surface of the atmosphere surrounded by an electrode.

Unlike the prototype between spaced along the electric field lines included electrodes load. In the absence of the device in contact with the outer surface of the planet electrodes structurally combined with the atmospheric gas ionizers. The current-carrying live parts of the device are electrically isolated from the supporting structure.

The farther apart the electrodes are separated, the higher the electric field strength near their surface and the greater the spreading rate of free charge carriers in the surrounding gas. Surrounded by the atmosphere, the electrodes are advantageously placed in the vertically spaced points of the supporting structure. Spreading of charge carriers in the atmosphere is facilitated by free movement of gas at the electrodes and the absence of other voltage concentrators around the device.

If there is a contact between the device and the planet, the lower electrode is an earth electrode. This provides a low electrical resistance to the passage of atmospheric electric current through the ground. If there is no contact of the device with the planet, the atmospheric electric current created by it can pass only through the gas discharge channel. In this case, all electrodes surrounded by atmosphere (both upper and lower) are structurally combined with ionizers of atmospheric gas. Thus, the uninterrupted conversion of the energy of the atmospheric electric field into the energy of the electric current flowing through the load is ensured. Further useful conversion of this energy into heat, work or electricity is accomplished by choosing the type of load (heater, electric motor or other electrical equipment).

The effect of the essential features of the claimed invention on the resulting technical effect is as follows. The supporting structure ensures the correct orientation of the device in the atmospheric electric field, which coincides with the direction of its lines of force. It keeps the electrodes spaced along the field lines at the required distance, provides mechanical strength of the device and integrates its individual parts into a single whole. Electrodes should be moved apart from each other for the maximum technically possible distance. Proportional to the distance increases the strength of the electric field on their outer surface, which increases the mobility of charge carriers in the surrounding atmosphere and facilitates the flow of electric current through it.

If there is a contact between the device and the planet, the lower electrode is an earth electrode. This is the simplest, cheapest and reliable way to provide low resistance to the current flowing through it into the ground. Surrounded by the atmosphere, the electrodes are mounted on a supporting structure. This ensures the stability of their spatial position in an external electric field. Ionizers of atmospheric gas are structurally combined with the outer surface of the atmosphere surrounded by an electrode. This ensures a constant presence of a sufficient number of free charge carriers in the space adjacent to the electrodes and the free movement of these charges along the lines of force of the electric field. Thus, an electrical contact is provided with a low resistance between the solid electrodes and the atmospheric gas. The strength of a current passing through such a contact within a wide range does not depend on the strength of the external electric field and is determined only by the capacity of the ionizers. This guarantees the uninterrupted availability of energy, regardless of external factors, minimizes the power consumption for maintaining the channel of a non-self-sustaining electrical discharge through a neutral atmosphere and prevents the occurrence of inrush currents through the device in conditions of thunderstorm activity.

If there is no contact of the device with the planet, the ionizers of the atmospheric gas are structurally combined with the outer surface of all the electrodes surrounded by the atmosphere, both upper and lower. This is the only available way to ensure the flow of electric current through the atmosphere on both sides of the device deployed along field lines of force.

The load is included between the electrodes spaced along the lines of force of the electric field. This ensures its serial connection (together with the electrodes) to the circuit of the current passing through the atmosphere of a non-self-sustaining electric discharge. The product of the voltage drop across the load and the amount of current passing through it determines the useful power received by the device from the atmospheric electric field. The coefficient of efficiency of the device is determined by the balance between the load resistance and the transient resistance of the electrodes with the surrounding space (ionizer capacity). The lower the transient resistance of the electrodes, the greater the proportion of energy released in the load.

The insulation of the current-carrying parts of the device from the supporting structure ensures an optimal arrangement of the electric field lines in the surrounding space and helps prevent the flow of electric current through the conductive parts of the device that are not related to its electrical circuit.

The uninterrupted supply of energy is provided by the fact that the electric field of the atmosphere does not depend on the time of the year, exists around the clock in all weathers, is accessible anywhere in the troposphere. This energy resource of the atmosphere is constantly fueled by the full power of the planetary mechanism for separating electric charges.

Reliability of energy supply is ensured by the simplicity of the device, the lack of moving parts in its most important elements. Obtaining energy from the electric field of the atmosphere does not require large structures (dams, towers of great height) and complex technological methods. The maintenance of such a device is much simpler than in analogues.

The simplicity of the design of the elements of the device for obtaining energy from the electric field of the atmosphere follows from the fact that it contains only standard electrotechnical units without movable parts that do not require adjustment, adjustment and regular maintenance. Parts of the device and parts of the supporting structure do not require careful manufacturing.

The ease of transporting the device is achieved by the fact that it is manufactured with a minimum margin of safety, since it does not experience dynamic loads and, therefore, it does not require massive, large-sized units and parts. The device is made foldable or collapsible.

1 shows a general view of an apparatus for generating energy from the electric field of the atmosphere in the absence of contact with the planet.

The device comprises a vertically oriented support structure, for example a balloon, 1, electrodes 2, 3, air ionizers 4 and 5, insulators 6 and 7, cables 8 and 9, voltage converter 10 and a load, for example a radiosonde 11. In the surrounding balloon space, lines of the atmospheric electric field E. Electrodes, structurally combined with air ionizers, are attached to insulators. The balloon keeps the electrodes at a sufficient distance from each other, and the cables connect them to the voltage converter. The voltage converter is connected to the payload electrically and is connected by a common housing.

The device works as follows. After switching on the device, the ionizers 4, 5 saturate the air surrounding the electrodes 2, 3 with free charge carriers. They start drifting through neutral air, moving along the lines of force of the atmospheric electric field E, additionally amplified by the spaced position of the electrodes on the balloon 1. The leakage of charge carriers from the electrodes is compensated by the constant work of the ionizers. A constant electric current flows through the channels of the non-self-sustained gas discharge 12 and 13 from the electrodes through the atmosphere. A difference of potentials appears between the spaced electrodes. They keep it due to insulators 6 and 7. After the appearance of the working difference of potentials (≈5 kV) on the electrodes, the voltage converter 10 switches on. Atmospheric electric current is closed through it via cables 8 and 9.

Determine the electrical power required for autonomous uninterruptible power supply of the payload. For example, to operate the equipment of a modern radiosonde, suspended to an aerostat, a constant electric power of 10 W is sufficient. Determine the limiting electrical power necessary to supply auxiliary devices and air ionizers. For example, in an amount not exceeding 150% of the useful value, that is, 15 watts. Taking into account operating conditions of current collectors, the limiting potential difference between open live parts of the installation is determined. For example, no more than 10 kV is recommended, but actually 5 kV is chosen. The maximum current in the discharge channel is calculated. In this case, no more than (10 W + 15 W) / 5 kV = 5 mA. This value sets the productivity of ionizers, structurally combined with the electrodes. The density of the vertical conduction current and the field strength in the troposphere at the calculated flight altitude are determined. For example, the conduction current is not more than 1.5 μA / m^2, the electric field strength is 2.2-3.5 V / m. Calculate the distance between the electrodes, their shape and design, ensuring efficient spreading of the charge carriers created by ionizers in the atmosphere. For example, the distance is 50 m, the shape of the receiving electrodes is a ball, the area of each is not less than 0.5 m^2. They fix the electrodes with insulators on the balloon and the suspension system, lay cables, mount a power converter in the container with the equipment.

In Fig. 2, a general view of the device for obtaining energy from the electric field of the atmosphere when the device is in contact with the planet is presented.

The device comprises an electrode 1, an air ionizer 2, an insulator 3, a supporting structure 4, a cable 5, a voltage converter 6, a ground connection 7, a connecting cable 8 and a payload (weather station) 9. In the surrounding space, electric field E. The electrode, structurally combined with the ionizer of air, is attached to the insulator. The stand keeps the electrode at a sufficient height, and the cable connects it to the voltage converter. The voltage converter is electrically connected to the ground through the ground and with the payload through the connecting cable.

The device works as follows:

After switching on the device, the ionizer 2 saturates the air surrounding the electrode 1 with free charge carriers. They begin to drift through neutral air, moving along the lines of the atmospheric electric field E, additionally amplified by the elevated position of the electrode on the column 4. The leakage of the charge carriers from the receiving electrode is compensated by the constant work of the ionizer. A constant electric current flows through the channel of the non-self-sustained gas discharge 10 from the electrode through the atmosphere. The electrode acquires an electrical potential with respect to the ground surface and retains it due to the insulator 3. After the working potential (≈25 kV) appears on the electrode, a voltage converter 6 switches on. The atmospheric electric current closes through it via cable 5 to ground 7.

Determine the electrical power required for autonomous uninterruptible power supply of the payload. For example, for the operation of a modern automatic meteorological station, a constant electric power of 100 W at a nominal voltage of 27 V is sufficient. The limiting electrical power necessary for supplying auxiliary devices and ionizers of air is determined. For example, in an amount not more than 50% of the useful, that is 50 watts. From the climatic conditions and design features of the current collector determine the limiting potential difference between the open live parts of the installation. For example, no more than 30 kV is recommended, but actually 25 kV are chosen. The maximum current in the discharge channel is calculated. In this case, no more than (100 W + 50 W) / 25 kV = 6 mA. This value specifies the productivity of the ionizer, which is structurally combined with the electrode. The electrical activity of the atmosphere (the density of the vertical conduction current and the field strength) in the given area is measured or found from tables. For example, the conduction current is not more than 0.1 μA / m^2, the electric field strength is 110-250 V / m. Calculate the height of the rise of the electrode over the terrain, its shape and working surface, sufficient for efficient spreading of charge carriers created by the ionizer in the near-earth atmosphere. For example, the height is not less than 10 m, the shape is a ball, the area is not less than 1 m^2. The calculations take into account the wind speed, the presence of other voltage concentrators, the geological structure of the ground and other significant factors. Establish the required height of the rack with an electrode on the insulator, arrange grounding, mount auxiliary electrical equipment and power converter.

Thus, uninterrupted energy supply of autonomous electrical equipment is ensured due to the free force of the atmospheric electric field. The device is advantageously distinguished by the lack of moving parts, the simplicity of the necessary structural elements and the ease of their transportation. It is more reliable than all the devices of autonomous power supply, including wind generators and solar panels, since the electric field of the atmosphere depends little on the time of the year, exists around the clock and is accessible anywhere in the world.

FIG. 4

METHOD AND APPARATUS FOR CAPTURING AN ELECTRICAL POTENTIAL GENERATED BY A MOVING AIR MASS

BACKGROUND AND SUMMARY OF THE INVENTION

The instant invention relates to a method and apparatus for capturing an electrical potential generated by a moving air mass. Specifically, the instant invention describes a method and apparatus for capturing an earth-air static electrical potential which is produced by an air mass moving over a stationary airfoil.

Known apparatus and methods of producing electricity from a moving air mass utilize windmills and windmill-driven turbines. Such devices are generally mounted on fairly high towers and require complex propeller systems to effectively drive electrical turbines. The systems also tend to have a rather large affect on the air mass as it passes over the blades of a particular windmill. As with the placement of any artificial barriers in an air mass, the air mass is disturbed, and turbulence is induced into the air mass. As a particular particle of the air mass reaches the next windmill, the induced turbulence results in less driving force on the blades of the secondarily driven windmill.

The present invention does not have a propeller system, nor does it induce significant turbulence into a moving air mass. It is well documented that an object, particularly an airfoil, which is moving relative to an air mass, develops a substantial static electrical charge on its surface relative to the air mass as the result of friction between the airfoil and the air mass. This naturally occurring static charge is particularly strong when the airfoil is a conductive surface, such as a metal-covered aircraft wing. For this reason, virtually all metal-covered aircraft employ static discharge strips along the trailing edges of airfoil surfaces in order to dispel any accumulated static electrical charge.

An object of the instant invention is to collect electrical energy from movement of an air mass over an airfoil.

Another object of the instant invention is to collect electrical energy with a non-complex collecting element.

A further object of the instant invention is to collect electrical energy from movement of an air mass over an airfoil with a substantially non-turbulence producing system.

A further object of the instant invention is to describe a method of collecting electrical energy from the frictional effects of an air mass moving over a conductive airfoil.

The electrical system of the instant invention includes a conductive airfoil, which is rotatably mounted on an insulated bearing, the airfoil being free to align itself with a moving air mass. A second component of the system is a ground rod which extends down to a water table level. Electrical leads are connected to a conductive portion of the airfoil and to the ground rod, and are then connected to a storage battery.

The method of collecting electrical energy from the system involves connecting the negative side of the storage battery to the airfoil and connecting the positive side of the battery to the ground rod. As an air mass moves over the surface of the airfoil, an electrical charge is produced and transmitted to the storage battery. Electrical energy may be drawn from the storage battery as needed.

These and other objects and advantages of the instant invention will become more fully apparent as the detailed description of the invention which now follows is read in conjunction with the drawings.

DESCRIPTION OF THE DRAWINGS

FIG. **1** is a front elevation of an earth-air electrical current friction generator constructed according to the instant invention, with portions broken away to show interior detail.

FIG. **2** is a top plan view of the generator of FIG. **1**.

FIG. **3** is a schematic plan view of a generator field constructed according to the instant invention.

FIG. **4** is a view of the generator field of FIG. **3**, taken generally along line **4**—**4** in that figure.

FIG. **5** is a graph depicting the relationship between current production and wind speed associated with the generator of FIG. **1**.

DETAILED DESCRIPTION OF A PREFERRED EMBODIMENT

Turning now to the drawings, and in particular FIG. **1**, an earth-air electrical current friction generator made according to my invention is depicted generally at **10**. The generator includes a metal airfoil, or conductive airfoil means, shown generally at **12**, which is supported by a rotatable airfoil mount **14** and an electrically conductive electrode **16**. A battery **18** provides storage capability for the collecting apparatus.

Airfoil **12** is vertically mounted above ground level. The airfoil is a zero-lift structure in the preferred embodiment, since both active surfaces are symmetrical. Airfoil **12** is formed of a conductive metal skin **20**, formed of lightweight aluminum sheeting in the preferred embodiment, over a frame **22** which is shown behind the cut-away portion of skin **20**. Frame **22** may be formed of any suitable material, such as wood, plastic or metal. In the preferred embodiment, frame **22** is a substantially square structure.

A wind vane **24** is mounted on the top and at one side of airfoil **12**. Wind vane **24** is also referred to as an air mass alignment means, and provides that airfoil **12** will be windfollowing.

An airfoil support bracket **26** is attached to the base of airfoil **12**. One end of a support post **28** is received within bracket **26**. The other end of post **28** terminates in a non-conductive airfoil bearing race **30** and is received within mount **14**. Bracket **26** and post **28** are electrically conductive and are electrically connected to skin **20**.

Rotatable airfoil mount **14**, or rotatable airfoil mounting means, electrically insulates airfoil **12** from electrode **16**, and is referred to herein as isolation means or isolator means.

Airfoil mount **14** is, itself, supported by an above-ground portion **16*a*** of electrode **16**. Portion **16*a*** terminates in a non-conductive electrode bearing race **32**. A bearing **34** is interposed race **30** and race **32**. The respective airfoil and electrode components are retained together by means of a fastener **36**, which is a nut and bolt combination in the preferred embodiment. Fastener **36** aligns with an airfoil axis of rotation **38**.

Mount **14** is enclosed by a cylindrical enclosure **40** which is secured to portion **16*a*** and which allows post **28** to rotate within a weathertight seal **42**. Enclosure **40** and seal **42** are, of course, electrically non-conductive.

Electrode **16** extends through whatever ground layers exist beneath the surface, which are depicted generally at **44**, and then extends into a permanent water table layer **46**. Extending electrode **16** into a water table provides an electrical surface which is as large as the water table. Although the generator would function if electrode **16** did not extend into a water table, the operation of the generator is greatly enhanced by extending electrode **16** to a water table, for reasons which will be explained later herein.

An electrical commutator **48**, and a grounding screw **50**, make electrical contact with post **28** and portion **16***a*, respectively. Commutator **48** is insulated from and fastened to enclosure **40** by bracket **48***a*. Commutator **48** is connected to a lead line **52** which is attached to battery negative terminal **18***a*, and screw **50** is attached to lead line **54** which is attached to battery positive terminal **18***b*. The commutator, screw and lead line comprise what is referred to herein as means for connecting, or connecting means.

Battery **18**, although represented in FIG. **1** as a solitary unit, may obviously include a plurality of units, connected in series or parallel, depending on the output of generator **10**. A pair of leads **56**, **58**, are shown coming off of battery **18**, and would presumably be attached to an electrical distribution system, possibly through an A.C. inverter. The battery and leads **56**, **58** compise an electrical system.

As an air mass moves over skin **20** of airfoil **12**, there occurs an exchange of ions between the air mass and the surface of the airfoil. This exchange takes place as an air mass moves over any stationary object. In most instances, however, the object is sitting on the surface of the earth, in electrical communication therewith, and a charge does not accumulate on the surface of the object. Since the airfoil of the instant invention is insulated from the earth, a static charge builds up on the surface of the airfoil as an air mass flows over the airfoil.

As the air mass moves over airfoil **12**, a collection of negatively charged ions builds up on the airfoil surface. Were there no electrical connection whatsoever between airfoil **12** and ground surface **44**, and were it not for the fact that eventually a charge built up on airfoil **12** would dissipate into the air mass, a charge would eventually build up on airfoil **12** of sufficient strength to arc, such as thc arc produced between a thunderstorm and the ground in the case of lightning, resulting in the complete discharge of the negative ions accumulated on airfoil **12**.

The electrical charge which accumulates on airfoil **12** is drawn off of the airfoil by means of commutator **48**, which is attached to battery **18**. A corresponding positive charge is drawn off of electrode **16** by means of screw **50**.

The surface area of airfoil **12** is defined by what is referred to herein as a cross-section square inch. This unit is depicted at **60** in FIGS. **1** and **2**. The unit is measured on both sides of the airfoil. The distance between the sides of the airfoil is not a factor. So long as the surface area in electrical contact with electrode **16** equals or exceeds the surface area of airfoil **12**, the generator will produce a current flow of 1-milliamp-per-square-inch of airfoil surface cross section with a wind speed of 7-miles-per-hour.

Because the airfoil collects negative ions, it is sometimes referred to as a negative collector element. Likewise, since electrode **16** acts as a source of a positive charge, it is sometimes referred to as a positive collector element, or conductive earth means.

Turning now to FIGS. **3** and **4**, a friction generator farm **62** is depicted schematically in FIG. **3**, and in a pictorial cross section side view in FIG. **4**. A generator farm, according to the instant invention, would include at least one conductive electrode **64**, placed in the ground down to the level of a permanent water table, which would act as a positive collector element. A plurality of airfoils is depicted by even numbers **66** through **80**. Electrode **64** is connected to a positive side of an electrical system by a conductive line **82**. Airfoils **66** through **80** are connected to a common negative lead **84** which connects to the negative side of an electrical system.

Turning now to FIG. **4**, a side sectional view of generator farm **62** is shown. Electrode **64** is placed in ground, represented by **44** as are the support posts for the airfoils. It should be noted that in this type of arrangement, a single commutator would be required within airfoil mounts **70***a*, **68***a*, **66***a*, **80***a* and **78***a*. An airfoil structure support post, represented at **70***b*, **68***b*, **66***b*, **80***b* and **78***b* may be formed from an electrically insulative material when a single electrode, like that shown at **64**, is utilized, thereby further simplifying the internal portions of the airfoil mount.

In addition to earth-air friction generators, a pair of lightning rod devices **90**, **92**, are shown in FIG. **4**. Rods **90** and **92** also are extended subsurface to provide protection from lightning strikes in the vicinity of generator farm **62**. A generator farm of the type described would be particularly susceptible to damaging lightning strikes were such lightning rods not provided.

Returning for a moment to FIG. **3**, a wind arrow **94** is depicted to show a prevailing wind and direction of air mass movement. It will be noted that airfoils **66** through **80** have aligned themselves with the wind indicated by arrow **94**. It should also be noted that with a generator farm in the layout proposed in FIG. **3**, there would be very little disturbance of wind flow by the airfoils of the generator farm. This is in extreme contrast to the turbulence and generally delaminating effect of conventional windmill generating farms.

It should also be obvious to those skilled in the art that the construction of the generator of the instant invention is many orders of magnitude less complex than the construction required for a conventional windmill-type turbine generator.

Turning now to FIG. **5**, a graph of current output per crosssection square inch mA/in^2 versus wind speed V (mph) is depicted. The above-described generator will produce 1-milliamp of electrical current per cross-section square inch with a 7-mile-per-hour wind. Generator output increases linearly, such that the generator will produce 10-milliamps per cross-section square inch in a 70-mile-per-hour wind. It should also be noted that very few known windmill turbine generators function in a 7- or 70-mile-per-hour wind. The generator of the instant application does not have such a limitation. The generator will produce current in any amount of wind, light or strong. As long as the structure is sufficiently durable to withstand a high wind, the system will continue functioning and producing an electrical current. Most systems are restricted to operations over a set wind speed range, generally in the 10- to 45-mile-per-hour range. Systems which produce electricity in extremely light wind conditions are very costly.

Assume for a moment, that an individual airfoil is constructed with sides which are 10-feet in length, thereby producing a cross section dimension on the order of 100-square feet, and further assume that ten airfoils are arranged similar to generator farm **62**, thereby resulting in a total cross section area of 1,000-square feet. The generator farm so described, when connected to a 12-volt D.C. system, and when excited by a wind of 7-miles-per-hour, will produce 1,728-watts of electrical energy.

Thus, a new method of capturing a usable electric current, and an apparatus for practicing the method described have been disclosed. While a preferred embodiment of the invention has been described, it is appreciated that variations and modifications may be made without departing from the spirit of the invention.

It is claimed and desired to secure by Letters Patent:

1. An earth-air electrical current friction generator which comprises

conductive earth means extending subsurface into a water table,

conductive airfoil means operatively associated with said earth means extending above surface into an air mass responsive to airflow to produce an electrical potential relative to said earth means,

isolation means electrically insulating said airfoil means from said earth means, said isolation means including a rotatable airfoil mounting means which allows said airfoil means to rotate in such an air mass and which supports said airfoil means above surface,

an electrical system, and

means for connecting said airfoil means and said earth means to said electrical system for conduction thereto of an electrical current.

2. An electrical charge collector which comprises

a positive collector element extending to a water table,

a negative collector element operatively associated with said positive collector element, said negative collector element being wind-following and including wind alignment means for aligning said negative collector element with a prevailing wind,

isolator means for insulating said negative collector element electrically from said positive collector element, said isolator means including a rotatable mounting which rotatably supports said negative collector element, and

connecting means for providing an electrical connection from each of said elements to an electrical system.

3. The collector of claim **2**, wherein said positive collector element includes at least one conductive electrode.

4. The collector of claim **2**, wherein said negative collector element includes at least one conductive airfoil.

"Tethers Open New Space Options" by Ivan Bekey, *Astronautics & Aeronautics*, 1983.

Primary Examiner—J. Woodrow Eldred
Attorney, Agent, or Firm—Arthur M. Dula

[57] **ABSTRACT**

The present invention comprises an electrodynamic tether structure and a method of use. The structure of the tether taught by the present invention is a short, wide, interconnected multiwire (compared to the long, narrow single wires of the prior art) conductive tether whose area maximizes electrodynamic drag while simultaneously minimizing the Area-Time-Product swept by the tether during its operating life. The preferred tether length is two kilometers to five kilometers. The preferred tether mass is one percent to five percent of the spacecraft mass. The method of operation comprises orienting the tether structure at an angle to the local vertical to maximize electrodynamic drag on the host spacecraft and minimize tether instability. The angle of 35.26 degrees is preferred.

FORCES AND TORQUES ON AN UPWARD DEPLOYED CONDUCTING TETHER DUE TO THE MOTION OF THE HOST SPACECRAFT THROUGH THE MAGNETIC FIELD OF THE EARTH.

FIG. 12

ELECTRODYNAMIC TETHER AND METHOD OF USE

TECHNICAL FIELD

This invention relates generally to apparatus and methods useful for changing the state vector of a space object when the space object is moving relative to a magnetic field. More specifically, the present invention relates to an apparatus and method of using a conducting tether to produce an electrodynamic force to deorbit a satellite from its orbit around a celestial body, such as the Earth, which has an associated magnetic field.

RESERVATION OF RIGHTS

This application is subject to certain rights of the U.S. government as a result of contracts between the U.S. government and the inventors.

BACKGROUND ART

The present invention has its principal utility in outer space, primarily for deorbiting satellites at the end of their useful life to mitigate the harm and reduce the liability created by the proliferation of space debris. In order to obtain a better understanding of the present invention it is helpful to understand the prior art of space tethers, especially tether dynamics and tether electrodynamics. The present invention may be more readily understood through a review of the experimental prior art and a mathematical analysis of electrodynamic space tethers.

Prior Art Tethers:

A tether was originally a rope or chain used to fasten an animal so that it grazed only within certain limits. Tethers have been used for decades in space to attach astronauts to their spacecraft.

In 1974 Professor Guiseppe Colombo, holder of the Galileo chair of astronomy at the University of Padua in Italy, proposed using a long tether to support a satellite from an orbiting platform. U.S. Pat. No. 4,097,010, which issued to Professor Colombo and Mario Grossi on Jun. 27, 1978, teaches a satellite connected by means of a long tether to a powered spacecraft. Colombo actively pursued the design of a tethered satellite system.

Several NASA experiments, such as the two Small Expendable Deployer System (SEDS 1 & 2) experiments and the Plasma Motor Generator (PMG) experiment used tethers in space. SEDS used a nonconducting tether. The PMG used a 500-meter conducting tether. The Tethered Satellite System flights in 1992 and 1996 (TSS-1 & 1R) used a 20,000-meter conducting tether.

On the TSS-1 mission the tether deployed only 260 meters (853 feet) before the deployer failed. On the TSS-1R the tether was deployed 19,500 meters. In the SEDS-2 flight, a 0.8-mm diameter, 20,000-meter long braided single-line tether was deployed to study tether dynamics and lifetime. Orbital debris or a meteoroid severed this tether in less than four days.

In the TSS-1R flight, the conducting single-line tether was severed after five hours of deployment. This failure was caused by an electric arc produced by the 3,500 volts of electric potential generated by the conductive tether's movement through the Earth's magnetic field.

The Tether Physics and Survivability (TiPS) satellite consists of two end masses connected by a 4,000-meter long non-conducting tether. This satellite was deployed on Jun. 20, 1996 at an altitude of 1,022 kilometers (552 nautical miles). Its tether is an outer layer of Spectra™ 1000 braid over a core of acrylic yarn. The yarn will "puff" its outer braid to two millimeters to "give it a larger cross section to improve its resistance to debris and small micrometeoroids", according to the National Reconnaissance Office (NRO), which is a sponsor of the TiPS mission. As of Jun. 21, 1997 the TiPS tether had survived one year.

The "Hoytether"™, an Improved, High-Reliability Tether:

In 1991, one of the present inventors, Robert Hoyt, invented a lightweight net-like structure that provides many redundant load-bearing paths. A number of primary load bearing lines running the length of the structure are connected periodically by diagonal secondary lines. The disclosed embodiment of this invention has the secondary lines firmly connected by knots to the primary lines. The secondary lines are connected only to the primary lines. At either end of the disclosed structure, a support ring enforces the cylindrical spacing between the primary lines. The secondary lines are designed with a small amount of slack. These secondary lines are only put under load if a primary line fails. This specific tether structure was disclosed to the public in 1992 (Forward, R. L., "Failsafe Multistrand Tether Structures for Space Propulsion", AIAA paper 92-3214, 28^{th} Joint Propulsion Conference, Nashville, Tenn., 1992 (hereinafter "1992 Hoytether structure"). This structure was named a "Hoytether". The term "Hoytether" is used throughout the remainder of this specification for this type of tether structure.

The present invention uses an improved Hoytether, which was invented by the same inventors as the present invention. This improved Hoytether is the subject of a copending PCT application. The Hoytether is discussed briefly in this specification to aid understanding of the present invention.

The 1992 Hoytether design teaches that the normally slack secondary lines have half the cross-section (0.707 the diameter) of the primary lines. There are twice as many secondary lines as primary lines, thus the mass of the secondary lines is equal to the mass of the primary lines. In an undamaged Hoytether, the primary lines carry the entire load, while none of the secondary lines are under load.

While the survival probability of a single-line tether decreases exponentially with time, the Hoytether can maintain a high, i.e. greater than 99 percent, survival probability for periods of months or years (forward and Hoyt, "Failsafe Multiline Hoythther Lifetimes", Paper AIAA 95-2890, 31st Joint Propulsion Conference, July 1995).

The Hoytether is essentially a tri-axial net structure, with 'primary' lines running along the length of the tether and two sets of 'secondary' lines connecting these primaries diagonally. They can be made by hand and connected with knots as is taught by the 1992 Hoytether structure. Because knotted connections severely limit the strength of a structure, it is desirable to use a knotless fabrication technique to achieve interconnections that have strengths approaching the limits of the constituent material. As these tethers may be many kilometers long; fast and inexpensive mechanical methods are required for their practical fabrication.

Hoytethers may be made by mechanical braiding, i.e. three-dimensional braiding, such as 3-D rotation braiding using braiding machines such as those developed by the Herzog Company in Germany (August Herzog Maschinenfabrik GmbH & Co., Postfach 2260.26012, Oldenburg, Germany. The specialized loom developed by the Nichimo Company of Japan (Nichimo Company Ltd., 2-6-2 Ohtemachi, Chiyoda-Ku, Tokyo, Japan) is used to produce "Ultracross" knotless fishing nets in which the individual strands are braided as a 4-braid line, and the strands are interbraided where they cross. This produces netting that has slipless interconnections that are very strong, approaching the maximum capability of the fiber. Such a loom could, with some modifications, produce the present invention's structure. Only two such machines exist, one in Japan, the other in Washington State. Unfortunately neither can work with the small line diameters needed to practice the preferred embodiment of the present invention. See generally, Ko, F. K., "Braiding", in *Engineered Materials Handbook, Vol. 1., Composites*. ASM International, Metals Park, Ohio, 1957. Pp. 519–528.

The most common 3-dimensional braiding machines are 4-step braiders based upon the designs of Maistre (German Patent P230-16986, issued 1973) and Forentine (U.S. Pat. No. 4,312,261, issued 1982). Braiding is accomplished by using pneumatics or solenoids to push the parts of the braiding machine to the proper positions. This is a slow process and making a Hoytether kilometers long with these machines would be very time consuming and expensive. The composites division of Albany International (Albany International Research Company, 777 West Street, Mansfield, Mass.) also produces a 3-D braiding machine. This machine uses modular braiding components that arc assembled breadboard fashion on a large wall.

Although braiding is the preferred technique, alternate fabrication methods such as Raschel knitting and crocheting can be used successfully. Multikilometer long Hoyththers are presently being produced for the inventors by the vendors Culzean Fabrics and Flemings Textiles using an electronically controlled crochet machine produced by Comez in Italy.

Space Tether Systems:

The prior art teaches the use of tethers in space applications. U.S. Pat. No. 5,163,641, issued on Apr. 9, 1990 to Yasaka, teaches the use of a powered spacecraft connected by a tether to a satellite. This tether is disconnected to change the state vector of the satellite. The state of the art of energy and momentum transfer using space tethers is discussed in Ivan Beckey's article "Tethering, a new Technique for Payload Deployment", Aerospace America, March 1997, at pages 36–40. Beckey concludes, "Tethers can perform the same functions as propulsive upper stages of direct payload injection, but at lower weight and cost per pound." U.S. Pat. No. 4,923,151, issued Mar. 1, 1988 to Roberts, Wilknson and Webster, teaches a tether power generator for earth orbiting satellites. U.S. Pat. No. 4,580,747, issued Mar. 15, 1983 to Pearson, teaches use of a long tether extending downward into the atmosphere from a satellite. The state vector of the satellite is changed by forces acting on a lifting body connected to the end of the tether. U.S. Pat. No. 4,824,051, issued Jan. 12, 1987 to Engelking, teaches passing an electric current through a conductive tether attached to a satellite to provide propulsive force to alter the orbit of the satellite. U.S. Pat. No. 5,082,211, issued Jan. 21, 1992 to Werka, teaches use of a tether to deorbit space debris. U.S. Pat. No. 4,727,373, issued Mar. 31, 1986 to Hoover, teaches an orbiting stereo imaging radar system having two spacecraft in synchronous parallel orbits connected by a tether.

Tether Dynamics:

In order to understand the forces that cause a tethered satellite to move upward and away from an orbiting satellite, for example, it is first necessary to explain briefly how a satellite remains in orbit. An orbiting satellite is acted on by the force of gravity which pulls it toward Earth, and by a centrifugal force, which pushes it away from Earth. The centrifugal force" (actually inertia) results from the motion of the satellite around its circular orbit. This is the same force that one can experience by swinging a ball around on the end of a string. A satellite is maintained in its orbit when it travels at the natural speed for its altitude and, as a result, the centrifugal force is equal to the gravitational force.

At the typical orbital altitude of 250 kilometers for a low-Earth orbit satellite, for example, a speed of approximately 7.6-km per second is required to create sufficient centrifugal force to balance gravitational attraction on the satellite. If the altitude is changed, the two opposing forces will no longer be in balance unless the satellite also changes its speed. A higher orbital altitude requires a slightly lower speed so the satellite will take longer to complete an orbit. Because of this, if two free-flying satellites are in orbits at different altitudes, the lower satellite will circle the Earth in less time than the satellite in the higher orbit.

If two satellites, at different altitudes, are connected to each other by a tether, they are forced to travel around their orbits together—in the same period of time, which is longer than the natural period of the lower satellite but shorter than that of the upper satellite. The lower satellite will, therefore, slow down below the natural speed for its orbit and will tend to fall to a lower orbit because the centrifugal force will now be less than the gravitational attraction of the Earth. An upward force in the tether that makes up the difference between centrifugal and gravitational forces holds it in place, however.

Correspondingly, the upper satellite will be accelerated above its natural orbiting speed (increasing its centrifugal force above the gravitational attraction) and will tend to move to a higher orbit. It, too, is held in place by an additional force (downward) in the tether. In other words, the net force downward on the lower satellite is balanced, through the tether, by the net force upward on the upper satellite. The effect of unbalanced forces on the two satellites is, therefore, to create tension in the tether. During the TSS-1 & 1R experiments, the inertia of the tethered satellite causes the satellite to rise above the orbiter as the tether is reeled out. Very close to the orbiter, there is little difference in the two orbits, and the tension force is insufficient to overcome friction in the deployer mechanism; therefore, until the satellite reaches a separation of approximately 1000-meters, the tension is augmented by small tether-aligned thrusters on the satellite. Beyond this point, the tension in the tether is the only force required.

By experimenting with a ball hung on a piece of elastic cord (a paddleball, for example) it is possible to simulate all the different types of oscillations that are possible on a space-based tether system. The elastic cord, representing the tether, may compress and stretch, causing the ball to bounce up and down (longitudinal oscillation). It also may move in a circular (skip-rope) motion or may develop wave-like motions (transverse oscillations). Even if the string itself remains straight, it is possible to get the ball swinging back and forth about its attachment point on the paddle like a child on a swing rope (pendulous motion).

Each type of motion occurs with a particular frequency, which depends on the length and tension of the tether. When the frequencies are different, the motions do not interact; however, at some tether lengths, the frequencies of two or more types of oscillation can become very close. At this point, energy can be transferred from one type of motion to another, a phenomenon known as resonance. For instance, the transverse oscillations in the tether may cause the satellite to swing back and forth in pendulous motion.

Many different factors may cause oscillations; the movements of the satellite or Shuttle are but two of these. For an electrodynamic tether, the skip-rope and pendulous oscillations are of particular interest. If a current is passed through a tether, the current will interact with Earth's magnetic field, resulting in a force that may produce skip-rope and pendulous oscillations. Because it is necessary to maintain control of the satellite, much study has gone into identifying the different types of possible motions and the methods used to control them.

One way to control the magnitude of those motions that cause a change in tension or transverse motion at the end of the tether is to have an end mass connected to the Hoytether that maintains a controlled tension on the tether, working much like a spring-loaded 'dog leash'. This may be as simple as a coiled spring, or as complex as an active control system that measures the tension and transverse forces on the tether and adjusts the applied tension according to a local or remotely operating algorithm.

Electrodynamic Effects of Conductive Tethers:

Electric potential is generated across a conductive tether by its motion through the Earth's magnetic field. Electromagnetic forces acting on a conductive tether in orbit can make the tether system behave like an electric motor or generator, thereby exerting a useful force to alter the state vector of the tether and any mass attached to it.

Electrodynamic tether propulsion is unlike most other types of space propulsion in use or being developed for space application today—there is no hot gas expelled to provide thrust. Instead, the environment of near-Earth space is being utilized to propel a spacecraft or upper stage via electrodynamic interactions.

A charged particle moving in a magnetic field experiences a force that is perpendicular to its direction of motion and the direction of the field. When a current flows through a long, conducting tether the electrons flowing through the tether experience this force due to the fact that they are moving along the wire in the presence of Earth's magnetic field. This force is transferred to the tether and to whatever the tether is attached (like a spacecraft, satellite, space station or upper stage). It can be an orbit-raising thrust force or orbit-lowering drag force, depending upon the direction of current flow. Operation in one mode allows boost from LEO to higher orbit while reversing the current flow provides negative thrust for deboost. The principle is much the same for an electric motor; reverse its operation and it acts as a generator. The current passing through the tether is returned through the ionosphere to complete the current loop with collection and emission occurring on opposite ends of the tether.

The PMG experiment demonstrated that a conducting tether can be used as both a motor and a generator. The TSS experiments, especially TSS-1R showed that very large voltages (about 3500 volts) can be generated by a sufficiently long tether.

Uses of an electrodynamic tether as an orbit raising and lower propulsion system has many advantages over competing systems:

a. It is nearly propellantless. Most other systems expel hot gases and require extensive resupply. To emit current, the electrodynamic tether propulsion system may use plasma contactors developed as a part of the International Space Station Program. These contactors consume less than 20 kg of xenon gas per year with a 50% duty cycle. The electrodynamic tether propulsion system can also use field emitter arrays, which emit electrons without the use of any gas.

b. It can change both altitude and inclination. The Earth's magnetic field is non-uniform and can therefore provide both in- and out-of-plane forces for inclination changes as well as altitude changes. This is of particular interest to payloads requiring polar orbits in that they can be launched on a small launch vehicle into a lower inclination orbit and have it raised in space by the proper phasing of current through the tether.

A demonstration of the propulsive capabilities of electrodynamic tethers was recently approved for a flight test in 1999. The Propulsive SEDS or ProSEDS mission, will fly as a secondary payload on a Delta II launch vehicle and deploy a 5-km conducting tether using the existing SEDS deployer concept. The ProSEDS experiment will be followed by the Electrodynamic Tether Upper Stage (EDTUS) experiment that will demonstrated the use of electrodynamic forces to change both the altitude and inclination of the experimental spacecraft. FIGS. **1B** and **1C** show the calculated electrodynamic thrust at several inclinations and the reentry time sensitivity of the ProSEDS tether, respectively.

One application for long-life conducting electrodynamic tethers is as a "Terminator Tether™" for removing from orbit unwanted Earth orbiting spacecraft at the end of their useful lives. When the mission of the satellite is completed, the Terminator Tether™, weighing a small fraction of the mass of the satellite, would be deployed. The electrodynamic interaction of the conducting tether with the Earth's magnetic field will induce current flow in the tether conductor. The resulting energy loss from the heat generated by the current flowing through the ohmic resistance in the conducting tether will remove energy from the spacecraft, eventually causing it to deorbit, thus reducing the amount of orbital space debris that must be coped with in the future.

In the following analysis, it is shown that the amount of energy loss generated by an electrodynamic tether is essentially independent of its length or area, and instead is primarily proportional to the tether mass and the physical properties of the conductor metal chosen. In the typical example calculated, a 1000-kg spacecraft can be deorbited from a 1000-km high Earth orbit by a 10-kg mass tether in a month, while a 1-kg tether can deorbit a 1000-kg spacecraft in less than a year.

To the knowledge of the inventors, Joseph P. Loftus of NASA/JSC first proposed the general concept of using an electrodynamic tether to deorbit spent satellites. (Joseph P. Loftus <JLoftus@ems.jsc.nasa.gov>, personal communication via email to Robert Forward, Monday Jun. 10, 1996 15:50:10.) In order to show that the Loftus deorbit concept was not obvious to those skilled in the art of electrodynamic tethers, Forward contacted the leading expert, Joseph Carroll, of Chula Vista, Calif., who built and participated in the flight test of the PMG. After being told of the Loftus concept in a telephone conversation, his reply in an Email message dated Aug. 5, 1996, was "such a system would be feasible . . . by it is still not obvious to me that it would be useful . . . "

Loftus was considering the use of electrodynamic drag from a conducting tether to achieve this goal of bringing the unwanted spacecraft down from its high orbit (where atmospheric drag is negligible) to a 200-km orbit, where atmospheric drag would rapidly finish off the task of removing the unwanted spacecraft from orbit. The tether Loftus was considering was a single-line, conducting tether, typically 1-mm in diameter, 1-km long, and, if made of aluminum, 2-kg in mass. He would include means at the ends of the tether to contact the ambient space plasma around the Earth to complete the current loop.

Unfortunately it is probable that space impactors would sever the 1-mm diameter, 1-km long single-line tether proposed by loftus within a 1/e lifetime of four months. This would produce orbital debris rather than removing it. The motivation for this work is the NASA Safety Standard NSS 1740.14 "(Guidelines and Assessment Procedures for Limiting Orbital Debris." The relevant portion of the Standard starts on page 6-3: General Policy Objective-Postmission Disposal of Space Structures. Item 6-1: "Disposal for final mission orbits passing through LEO: A spacecraft or upper stage with perigee altitude below 2000 km in its final orbit will be disposed of by one of three methods." The method of interest is the atmospheric reentry option, Option a: "Leave the structure in an orbit in which, using conservative projections for solar activity, atmospheric drag will limit the lifetime to no longer than 25 years after completion of mission. If drag enhancement devices are to be used to reduce the orbit lifetime, it should be demonstrated that such devices will significantly reduce the area-time product of the system or will not cause the spacecraft or large debris to fragment if a collision occurs while the system is decaying from orbit."

The NASA standard applies only to NASA spacecraft and even then only to completely new spacecraft designs. New versions of existing designs are to make a "best effort" to meet the standard, but will not be required to change their design to do so. The Department of Defense has adopted the NASA standard with the same provisos. An Interagency Group report has recommended that the NASA standard be taken as a starting point for a national standard. It is NASA's recommendation to the Interagency Group that the safety requirement be phased in only as spacefaring nations reach consensus internationally, which is being done through the International Debris Coordination Working Group whose members are Russia, China, Japan, ESA, UK, India, France, Italy, and the US.

Thus, although the NASA Safety Standard in its present form is not the "Law", the existence of the standard means that some time in the future a similar requirement may be imposed on all spacecraft. This could result in major growth in future space tether business, with a sale to every non-geostationary spacecraft being "mandated" by government safety regulations, somewhat as the sale of seat belts and airbags for every car are mandated.

In fact, three of the companies planning to set up "constellations" of low to medium orbit communications: Teledesic, Iridium and Odessey have committed their companies to abide by the spirit of NASA Safety Standard 1740.14 by using one means or another to deorbit their spacecraft before they reach end of life.

Problems with Prior Art Tethers:

All electrodynamic tether designs proposed by the prior art teach that the tether should be operated at a right angle to the magnetic field through which the tether is moving. This is a problem because the electrodynamic force acting on the tether causes the tether to align itself with the magnetic field force lines. To overcome this problem the prior art teaches the use of a large ballast mass attached to the end of the tether and/or use of a very long (tens to hundreds of kilometers) tether. The large ballast mass is expensive to take to orbit because it replaces useful payload. The long tether sweeps a larger Area-Time-Product during its useful life and thus is more likely to impact other space objects, either debris or another spacecraft.

Another problem common to all proposed prior art tethers is tether instability. If the tether produces a large electrodynamic drag force, which is desirable because a large drag force will cause the satellite to deorbit quickly, then the tether will be dynamically unstable. This instability can cause the tether to lose its effectiveness, act uncontrollably and even wrap around the satellite or otherwise malfunction. Experts skilled in the art of tether design have opined that this dynamic instability is inherently unavoidable in any electrodynamic tether system. The prior art solution, such as that presently being used in the ProSEDS experiment, has been to use a large ballast mass to increase the stabilizing gravity-gradient force and/or to limit the electrodynamic drag of the tether to less that the maximum that could be produced. In the ProSEDS experiment, the conducting electrodynamic tether is five kilometers long. To insure stability, it will be augmented by a 20–35 kilometer long non-conducting tether, which to further have stability will have a 40 kilogram ballast end mass.

Yet another problem of all proposed prior art electrodynamic tether systems is how to radiate away the energy produced by the tether's operation. A satellite moving at an orbital velocity of 18,000 miles per hour has a kinetic energy of over 10,000 calories per gram. To put this amount of energy in an understandable perspective, it may be noted that when nitroglycerine explodes it produces about 1,500 calories per gram. Prior art designs of electrodynamic drag tethers teach the use of the electrical energy generated by the tether to charge batteries or operate electronics, with the excess energy being converted into heat by a resistive load. This excess heat must be radiated to the space environment or it will melt the resistive load. Thus the resistive load, and/or its associated radiator structures, must be massive and replace useful payload.

DISCLOSURE OF THE INVENTION

The present invention comprises an electrodynamic tether structure and a method of use. The principal industrial utility of the present invention is to deorbit satellites in Earth orbit at the end of their useful life. This embodiment of the present invention is sometimes referred to in this specification as a "Terminator Tether™" because it terminates the orbital lifetime of the host spacecraft. The structure of the tether taught by the present invention is a short, wide, interconnected-multiwire (compared to the long single wires of the prior art) conductive Hoytether whose area maximizes electrodynamic drag while simultaneously minimizing the Area-Time-Product swept by the tether during its operating life. The preferred tether length is two to five kilometers. The preferred tether mass is one to five percent (1%–5%) of the spacecraft mass. The method of operation comprises orienting the tether structure at a 35.26-degree trailing angle to the local vertical to maximize electrodynamic force on the tether while avoiding tether instability and allowing use of a small tether end mass.

The present invention also teaches that the satellite-tether system may be rotated around its common center of mass to centrifugally produce tension force in the tether structure to oppose forces causing tether instability. The angle of the conductive tether structure of the present invention with respect to the velocity vector of the host spacecraft may be controlled by the method of the present invention so it interacts with the encountered magnetic field to induce a maximum current flow in the tether. This produces maximum electrodynamic drag. All or a portion of this electric power may be stored and then controllably applied to the conductive tether to produce an induced electrodynamic force. This induced electrodynamic force may by used to enhance the drag force, to rotate the tether-satellite system and/or to provide satellite propulsion, i.e. to change the state vector of the satellite for any useful purpose, e.g. to avoid collision or to change the host spacecraft's orbit to an orbit more favorable for more rapid deorbiting.

The present invention also teaches a tether structure that also functions as a thermal radiator and/or plasma contactor. An embodiment of the present invention using conducting elements of the satellite, e.g. the solar arrays, as electrodynamic tether structures is also disclosed.

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention may be better understood with reference to the following drawings:

FIG. **1***a* is a graph comparing the survival probability of a single line tether as taught by the prior art to the Hoytether used by the present invention.

FIG. **1***b* is a graph showing the level of electrodynamic thrust for a 10 kilometer, 10 kilowatt tether at various altitudes and inclinations.

FIG. **1***c* is a graph showing reentry time sensitivity of a five kilometer ProSEDS tether for several conditions of current flow in the electrodynamic tether.

FIGS. **2***a*, **2***b* and **2***c* show the Hoytether structure used by the preferred embodiment of the present invention.

FIG. **2***d* shows the Hoytape structure used by the preferred embodiment of the present invention.

FIG. **3** is a block electrical diagram of an electrodynamic tether system.

FIG. **4** is a graph showing a graph of the Area-Time product for three separate levels of exospheric temperature (for neutral drag calculations) and for two separate assumptions regarding tether mass and power drawn from the ambient plasma (for the Terminator Tether™ calculations).

FIG. **5** is the percent additional mass required in orbit to drop the perigee of a circular orbit at altitude, at, to a value of 200 kilometers using standard chemical rocket as taught by the prior art for deorbiting unwanted spacecraft.

FIG. **6** is a deorbit tether system shown operating with its electrodynamic tether at a trailing 35.26-degree angle to the encountered magnetic field, as is taught by the preferred embodiment of the present invention.

FIG. **7** shows an embodiment of the present invention in which the electrodynamic tether—satellite system is rotated about its center of mass to avoid tether instability.

FIG. **8** shows an embodiment of the present invention wherein the tether is powered to provide induced electrodynamic force.

FIG. **9** shows an embodiment of the present invention wherein the solar power system structure of the satellite is used as an electrodynamic tether.

FIG. **10** shows the use of a portion of the tether structure as a thermal radiator and plasma contactor.

FIG. **11** shows the braiding of an ohmic resistive load into the tether structure.

FIG. **12** is a force diagram showing the forces and torques on an upward deployed conducting tether due to the motion of the host spacecraft through the magnetic field of the Earth.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

The principal industrial utility of the present invention is the deorbiting of satellites in Earth orbit, which necessarily can happen only in outer space. Until the present invention is reduced to actual practice by use with satellites in outer space and a body of practical experience is thereby obtained, the present invention can only be constructively reduced to practice, such as by this written specification and its associated drawings, diagrams and graphs and by reference to electric measurements made on conducting tethers in space by the PMG and TSS experiments. The inventors provide herein a detailed discussion of the theory of the present invention to help those skilled in the art of aerospace and tether engineering to understand the present invention and to make and use the best embodiment of the present invention known to the inventors at the time this specification was prepared, without undue experimentation.

Although the present invention is discussed in this specification in its preferred embodiment as a means of deorbiting satellites, it must be emphasized that discussion of this specific use in no way limits the broad scope of the present invention. The present invention can be used to change the direction and speed, i.e. the state vector, of any space object providing that object is in motion relative to any magnetic field. This magnetic field may be that of the Earth or of any other celestial body, for example Jupiter or the sun.

In this specification the material forming the structure of the electrodynamic tether is specified as being a conductor. For example, a metal, such as copper or aluminum wire could be used. Likewise, nonmetallic conductor, such as carbon nanotubes, or a conductive polymer could form the conductive structure of the tether.

FIG. **1***a* shows the survival curve for a Hoytether as used by the present invention vs. the survival curve of a prior art single line tether. The survival probability curve of the Hoytether as a function of time does not conform to the well known "1/e decay" shape of a single-line tether. The Hoytether can maintain a high level of survival probability, about 99 percent, until it nears its 'lifetime'. Its survival probability then drops rapidly to zero. A detailed mathematical analysis of the difference between Hoytether and single tether survival probabilities is given in Appendix E "Small Impactor Survival Probabilities of Hoytethers" and Appendix F "Large Orbital Debris Survival Probabilities of Hoytethers", both contained in the Final Report of NASA Contract NAS8-40545. The resulting cut probability with time for the Hoytether has a "bingo curve" shapes. In a bingo game, at least five numbers must be called before anyone can win, and usually many numbers have to be called before one of the bingo cards gets five in a row. In the Hoytether at least four cuts must happen at the same level before any failure occurs, and many cuts have to be made before any one of the levels has all four lines cut. The bingo curve has the property that the probability of survival stays very high for periods short compared to the lifetime. The probability of survival is greater than 99% for periods shorter than 10% of the lifetime. This is much better performance than the 1/e curve of a single line tether, where the probability of survival is only 90% at 10% of the 1/e lifetime.

FIG. **1***b* shows the calculated level of electrodynamic thrust, in Newtons, produced by a ten kilowatt, ten kilometer single conductor tether at altitudes between 200 and 1400 kilometers and at orbital inclinations between zero degrees and eighty degrees.

FIG. **1***c* is a graph showing the reentry time sensitivity calculated for a five kilometer ProSEDS single conductor tether at altitudes between 200 and 500 kilometers with current flow in the tether between on flow and one ampere.

FIGS. **1***b* and **1***c* are the work of Enrico Lorenzini of the Smithsonian Astrophysical Observatory from his study "Performance Evaluation of the Electrodynamic Tether Tug", NASA/MSFC Grant NAG8-1303 (Nov. 12, 1966). They show that experts in the field believe that the present invention will have industrial utility, as the current flow of one ampere in FIG. **1***c* decreases the deorbit time for the calculated case from more than 180 days to less than 20 days.

FIG. **2***a* is an isometric drawing showing the generally cylindrical structure of the Hoytether. In FIG. **2***a*, primary lines **201** and **203** are shown connected via secondary lines **211**. In FIG. **2***b*, which is a schematic illustration of the structure shown in FIG. **2***a*, primary lines **201**, **203**, **205**, **207** and **209** are connected, each to their respective adjacent primary lines, by a plurality of secondary lines **221**. These connections, for example as shown at interconnection **213**, are made by knotless, slipless interconnections, such as Soutache braiding of twisted connections.

FIG. **2***c* shows the Hoytether structure of FIG. **2***b* but with a severed primary line **205** at breakpoint **215**. The second level of secondary lines **217**, shown as bold lines in FIG. **2***c*, redistribute the load from the severed primary line **215** at point **217** back to line **215** at points **219** and **221**, above and below the break, respectively.

For the electrodynamic tether, a preferred embodiment would be to unroll the tubular Hoytetherr™ into a flat Hoytape™ as shown in FIG. **2***d*.

FIG. **3** generally shows the arrangement of functional elements of an electrodynamic tether system. Of course such a system must have a means of attachment to the spacecraft, a deployer, the tether itself, some form of space plasma cathode contactor, some form of space plasma anode contactor, a power dissipation system, and a communication and control system. Each of these individual elements are known in some form to those skilled in the art of aerospace engineering. Thus the present inventors do not feel it is necessary to describe them in detail in this specification.

In FIG. **3**, a space object **301**, i.e. a satellite in Earth orbit, or any other space object either natural or man made, is physically connected to the tether system. The tether system comprises a deployer **303** from which a conductive Hoytether **305** having a bare segment **307** extends upward from space object **301**. The positively biased anode end **309** of tether **305** collects electrons from the ionosphere as space object **301** moves in direction **310** across the Earth's magnetic field. These electrons flow through the conductive structure of the Hoytether to the power system interface **311**, where it supplies power to an associated load, not shown. The electrons then flow to the negatively biased cathode **313** where electrons are ejected into the space plasma **315**, thus completing the electric circuit.

In order to allow those skilled in the art to better appreciate the broad scope of the present invention, the inventors will now provide an example using specific tether and system values to compare the Terminator Tether™ to prior art means, ie a rocket, for deorbiting a satellite.

Terminator Tethers™:

When an Earth orbiting conducting space tether moves through the magnetic field of the Earth, an electric field is generated in the tether that is proportional to the velocity of the conductor, the magnetic field strength of the Earth, and the angle between the conducting tether and the magnetic field lines. From data obtained during the various electrodynamic experiments that have been conducted in space to date, such as the PMG, TSS-1, and TSS-1R experiments, a typical value of the generated emf per unit length of tether of E=100–200 Volts/kilometer can be assumed. The electric potential V developed at the ends of a tether of length L is then V=EL. For a tether of length L=10 km, the electric potential developed is V=1000 V. For calibration, the 20-km long TSS-1R tether, at the moment of failure, was developing a potential of 3500 volts, which is 175 volts/km.

The mass of a conducting tether of length L, cross-sectional area A, and densin, d is given by m=dLA. Typical values for the density are d=2700 kg per cubic meter for aluminum and 8900-kg per cubic meter for copper. For a typical aluminum tether of mass m=10 kg and length L=10 km, the cross-sectional area will be A=0.37 mm squared. If this were a solid-wire single-line tether, the diameter of the wire would be D=0.69 mm (21.5 gauge). If this were an 18 line tubular Hoytether, the diameter of the lines in the Hoytether would be D=0.16 mm (34 gauge).

The resistance of a conducting tether of length L and cross-sectional area A is given by R=rL/A, where r is the resistivity of the conductor in nano-ohm-meters (nΩ-m). Typical values for the resistivity are r=27.4nΩ-m for aluminum and 17.0 -nΩ-m for copper. For the m=10 kg aluminum tether of length L=10 km and cross-sectional area A=0.37 mm squared at 20 degrees C, the end-to-end resistance is 750 Ω. This value of resistance is the essentially the same whether the conductor area is concentrated into a single-line tether or divided up into many lines as in a multiline Hoytether.

The current I generated in the conducting tether by the electric potential V between the ends of the tether applied across the tether resistance R is I=V/R. For the 10 kg mass aluminum tether of length L=10 km, electric potential V=EL=1000 volts, and resistance R=750 Ω the current is I=V/R=1.33 Amps. Currents near these values were measured in the TSS-1R experiment at the time of failure. At the time of failure of the TSS-1R tether, none of the plasma contactors on the Space Shuttle or the Italian Satellite were operating. Thus the current was being collected by the conductive surface area of the Space Shuttle and the Italian

Satellite at the two ends of the tether. The Space Shuttle area is quite large, so it was not the limiting factor in current collection. The diameter of the Italian Satellite was 1.6 m, which would give it an effective plasma contact area of about 8 square meters. This shows that, if the plasma contact area of the ends of a conductive space tether can be make large enough, then ampere level currents can be extracted from the ambient space plasma without the use of space plasma contactors.

The power dissipated as ohmic heating in the tether is given by P=IE. For an aluminum tether of mass m=10 kg, resistivity r=27 nΩ-m, and density d=2700 kg/cubic meter, subjected to an electric field of E=100 V/m, the power dissipated in the ohmic losses of the conductor is P=IV=1330 Watts. For a 1 kg mass tether, it would be still a considerable 133 Watts of dissipation.

There will no doubt be additional dissipation of energy in plasma ohmic losses, plasma wave generation, and plasma ion acceleration, but the ohmic losses in the conducting tether alone are sufficient for the task of deorbiting an unwanted spacecraft massing 100 to 1000 times more than the tether.

The decay time of a metric ton spacecraft moving from a 1000 km altitude orbit to a 200 km altitude orbit with an energy difference of dU=3.3GJ, when its energy is being dissipated at a power of P=1330 W by an aluminum tether massing just 10 kg, or 1% the mass of the spacecraft, is about one month. This is a remarkably short time, and indicates that the concept of using a conductive tether to deorbit a spacecraft is indeed feasible. If the aluminum tether massed only 1 kg, or 1/1000th the mass of the spacecraft it was deorbiting, then the decay time would rise to 10 months, still a reasonable value.

In reality, of course, the actual decay time will be longer than this. If the electrodynamic drag force is very large, and becomes larger than the gravity gradient forces pulling on the ends of the tether (which force is proportional to the mass of the tether), then the tether will tend to align itself along the magnetic field lines instead of across them, and the drag force will decrease because of the small angle between the conductor length and the magnetic field lines. The tether will then settle into an angle determined by the balance between these two forces.

Is the Terminator Tether™ theoretically a better means than atmospheric drag or a rocket engine for deorbiting satellites at the end of their useful life?

In the formula for da/dt (change in altitude per change in time), using the assumptions of near-circular spiral trajectories, the Area-Time-Product (Z), the criteria by which NASA judges compliance with Safety Standard 1740.14, is given by:

$$Z = A\int dt = -\frac{m}{C_D}\int \frac{da}{\rho(a)\sqrt{\mu a}},$$

where ρ(a) is simply the density as a function of semi-major axis. Thus, for a static atmosphere, the problem of area-time product is reduced to quadrature. Note that the area-time product depends only on the density profile and the ratio of spacecraft mass to drag-coefficient and is linearly related to that ratio.

The basic altitude-dependence of the atmospheric density, represented here by ρ(a) can be expressed in a low-order power series of ln(density)=f(ln(altitude)), so that it will be possible to develop a representation of the log—log relationship between altitude and density. The three static levels of atmospheric density are modeled as 5th order polynomials in the natural log of the altitude and are representative of well known atmosphere models, for example, Jacchia, L. G., "Thermospheric Temperature, Density, and Composition: New Model," SAO Special Report 375, March 1977. 2. Anon., Marshall Space Flight Center, "Long-Range Statistical Solar Activity Estimation," Atmospheric Sciences Division, 1989.) The values of exospheric temperature are reasonable (about 2-sigma) high and low solar activity values of 1400 and 800 kelvins respectively. The mean value is taken to be 1100 kevins.

FIG. 4 shows a graph of the Area-Time product for three separate levels of exospheric temperature (for neutral drag calculations) and for two separate assumptions regarding tether mass and power drawn from the ambient plasma (for the Terminator Tether™ calculations). The density profiles for the three values of exospheric temperature represent the extremes and mean values to be expected during the next several decades. The exospheric temperature goes through a cycle of about an 11 year period with maximum about 1400 kelvins and minimum about 800 kelvins.

The tether calculations include an inherent assumption that the Terminator Tether™ transfers all the energy extracted from the ambient space plasma into drag that decreases the orbital energy of the spacecraft at a rate given by the power drawn by the tether. Thus, the change in energy for a spacecraft of mass m at an initial altitude h is given by the expression:

$$\Delta E = -m\left\{\frac{\mu}{2(R_e + h)} - \frac{\mu}{2(R_e + 250)}\right\},$$

and the time required to effect this change in energy of the mass, m, is just

$$\Delta t = \Delta E / P,$$

where P is the power drawn by the tether from the ambient plasma charge.

The curves for 1% and 5% tethers do not include the effects of atmospheric drag because the electrodynamic drag is orders of magnitude greater than the neutral atmospheric drag. At altitudes greater than about 700 km, the electrodynamic drag is 200 to 3000 times greater than the neutral drag forces.

It is clear, from FIG. 4 that the Terminator Tether™ concept is far superior to neutral drag in removing spacecraft from orbit, no matter how much additional area is added to the passive spacecraft to increase the atmospheric drag. The analyst should note that FIG. 4 is proportional to mass; that is, the Area-Time-Product values should be multiplied by the mass of the spacecraft and divided by 1000 kg. This is true for the neutral drag and Terminator Tether™ curves alike. The power levels assumed for the 1% and 5% tethers are only 80% of their theoretical values. This is done to provide a 20% margin on the power available from the ambient plasma and electrodynamic gradient.

Conventional rocket mechanisms can remove spacecraft from orbit, but this mechanism is apparently not viable from mass considerations when these factors are compared with the capabilities of the Terminator Tether™. A satellite owner may decide to satisfy the NASA safety requirements by adding a small solid motor and the associated hardware, software, sensors and structure to make the package independent, to be used to deorbit the spacecraft in case the main spacecraft power, attitude, or propulsion system fails.

The requirements of such a rocket motor system are more stringent than those attributed to ordinary spacecraft. The rocket motor deorbit system must operate when some or all other systems of the spacecraft have failed. These more stringent requirements are balanced by lesser requirements of performance. The backup system must simply deorbit the spacecraft; it does not have to perform all the other duties of the spacecraft. But the backup system must know when to fire under all kinds of anomalous situations, including tumbling, offset of center of mass (because of loss of parts due to collisions), and lack of knowledge of the orbital position.

FIG. **5** shows the percent additional mass required by the rocket motor system to drop the perigee of a circular orbit at some initial perigee altitude to a value of 200 km. The atmospheric drag at this 200 km perigee altitude will remove any spacecraft (in the range considered) from orbit in a few revolutions. The contours of constant stage propellant mass fraction, λ, range from low values of 0.5 through reasonable values of 0.65 to 0.7, up to the values associated with the best solid motors ($\lambda \nabla 0.93$) without adding any extra hardware to the emergency stage. An effective, independent stage to provide a retro deltaV of from 50 to 325 m/s will almost certainly have a λ of the order of 0.6 to 0.75. If the emergency stage is required to perform its own attitude determination, the stage propellant mass fraction may be as low as 0.55 or 0.50. Note that the additional mass, shown in FIG. **5**, must also be lofted to orbit in the first place, to provide the mass on orbit for the originally intended service. The stage propellant mass fraction, λ, is a key stage performance parameter that describes the ratio of the mass of propellant to the mass of the stage. That is $\lambda=m_p/(m_p+m_I)$, where m_p is the mass of the propellant and m_I is the mass of everything else in the stage (not including the payload or any stages above or below the stage being considered). Typical independent small rocket stages have values of λ from 0.60 to 0.75. The curves of stage propellant mass fraction are shown as straight lines (a minor approximation) and are included only from 0.5 to 0.95, the extremes of reasonable design practice.

These calculations that show, beyond any reasonable doubt, that the Terminator Tether™ concept is far superior to conventional mechanisms such as drag enhancement devices or small rocket deorbit propulsion systems. The superiority is measured in terms of Area-Time-Product, NASA's measure of the likelihood of collision with other spacecraft in the path of the descending spent member of a constellation. Tether calculations were made using conservative assumptions that the power extractable from the ambient plasma and electrodynamic gradient is only 80% of the theoretical power available to a perfect tether crossing the magnetic field lines at a right angle, i.e. normally.

The following analysis is presented by the inventors to help those skilled in the art to better understand the present invention when it is used as a Terminator Tether™ for removing from orbit unwanted non-geostationary Earth-orbiting spacecraft at the end their useful lives. The primary result of that analysis is that the electrical power P in the tether that is converted into heat by the resistance of the tether and radiated away into space will remove energy from the spacecraft, causing it to rapidly deorbit, thus reducing the amount of orbital space debris that must be coped with in outer space. Tether electric power P is given by:

$$P=(vB)^2m/2rd$$

where m is the mass of the conducting tether, r and d are the resistivity and density of the conducting material, and v is the velocity of the spacecraft's motion through the Earth's magnetic field B. For a m=10 kg tether of aluminum with resistivity of r=27.4 nΩ-m and density d=2700 kg/m^3, moving at a velocity v=7037 m/s relative to the Earth's horizontal magnetic field B=26.5 μT, the power dissipated is P=2350 W! This energy loss in the form of heat must necessarily come out of the kinetic energy of the host spacecraft. For a typical example, a 1000 kg spacecraft in a 1000 km high orbit subjected to an energy loss of 2350 J/s from a 10 kg tether (1% the mass of the host spacecraft) will be deorbited in a few weeks.

Power levels of the magnitude estimated in the previous paragraph have been measured in a real orbital space experiment, the TSS-1R mission carried out on the Shuttle Orbiter in 1995. In that experiment, a large Italian spacecraft, 1.6 m in diameter, was deployed upward from the Shuttle Orbiter at the end of a conducting copper wire tether covered with electrical insulation. As the tether was slowly deployed upwards, a series of measurements were made of the open circuit voltage induced in the tether by its motion through the Earth's magnetic field. The voltage between the end of the tether and the Orbiter ground varied from zero volts at the start to 3500 V when the amount of tether deployed approached its maximum length of 20 km. Periodically, the end of the tether was connected either to one of two different electron guns, which supplied contact to the surrounding space plasma, or to the Orbiter ground. The bare surfaces of the Shuttle Orbiter proved to be a surprisingly good plasma contactor via a combination of ton collection and secondary electron emission. The current flow through the tether was deliberately limited by control circuits and the current capacity of the electron guns to about 0.5 amperes, but power levels of 1800 Watts were reached.

The tether was intended to have a fully deployed length of 20 km, but at a deployed length of 19.5 km, when about 3500 V was being induced at the end of the tether inside the Orbiter reel mechanism, a flaw in the insulation allowed an electrical spark to jump in an uncontrolled manner from the tether to the Orbiter ground. With no control circuits to keep the current level down to 0.5 amperes, the current flow jumped to 1.1 amperes, and the total power generated was P=3850 Watts Most of this energy went into the electrical arc, which burned through the tether, causing it to break and halting the experiment. This experiment showed that large areas of bare conducting material, such as that provided by the 8 square meter area of the Italian spacecraft at one end of the tether and the very large surface area of the Shuttle Orbiter spacecraft at the other end of the tether, can collect and emit amperes of current, while thousands of volts of potential can be generated by sufficiently long tethers moving at orbital speeds.

Thus, both theory and experimental data collected in the space environment indicate that significant amounts of electrodynamic drag force can be obtained from a low mass conducting tether attached to a host spacecraft, provided the ends of the conductor can exchange sufficient numbers of electrons with the surrounding space plasma.

Experimental data from the TSS-1R data also produced the amazing result that the efficiency of a bare metal surface in "contacting" the space plasma is many times better than the standard theory would predict. The 8 square meters of bare surface area of the Italian spacecraft were sufficient to collect the 1.1 A of electron current. This amount of area is easily replicated by a few hundred meters of bare wire, considering that the effective collection diameter around the wire is the Debye length, which is a few centimeters at the typical values for space plasma density and temperature.

Because of this result, that a bare wire can easily collect electrons, Les Johnson, Nobie Stone, Chris Rupp, and others at NASA Marshall Space Flight Center have formed a team, which includes the present inventors, which is embarked on a new flight experiment. The experiment is scheduled for a piggy-back flight on a Delta II launch of an AF Global Positioning Satellite in early 2000. The goal of the experiment is to demonstrate that electrodynamic drag from a wire moving at orbital speeds through the Earth's magnetic field will create a large enough electrodynamic drag force to deorbit the Delta II second stage, whose mass is greater than 1000 kilograms, in a few weeks. This is essentially a demonstration of the Loftus electrodynamic drag deorbit concept and the first step in the development of a Terminator Tether™.

The ProSEDS (Propulsion Small Expendable-tether Deployer System) mission will use a 5 km long copper wire conductive tether massing 18 kg connected to a 20–35 km long nonconducting tether, which is in turn connected to a 25–40 kg ballast mass. The total of 25–40 km of tether length and the 25–40 kg ballast mass on the end will provide enough gravity gradient force to keep the tether aligned near the zenith, so that the direction of the current in the tether is at right angles to both the direction of the spacecraft motion in the nominal EW direction and the Earth's near-equatorial magnetic field in the nominal NS direction.

An important feature of the ProSEDS experiment is that it is designed to be completely self-powered. It uses a battery to initiate deployment and to power up the plasma contactor, but once current is flowing through the tether, some of the power is tapped off and used to recharge the battery. The battery, in turn, powers the current control electronics, the telemetry, system, and the plasma contactor. The ProSEDS mission will not be designed to allow ground control changes in operation, primarily because of the increase in complexity and cost associated with that option.

The present invention is the use of a small, low-mass deployer/controller package containing a large collecting area, short length, multiline space tether, such as a Hoytape mesh made of aluminum wire, as a "Terminator Tether™" for a constellation spacecraft. The Terminator Tether™ would be deployed when the host spacecraft is no longer working or no longer wanted. The electrodynamic drag from the Terminator Tether™ would rapidly remove the unwanted spacecraft from the constellation and a few weeks later complete the deorbit of the host spacecraft from space by burnup in the upper atmosphere of the Earth. For a Terminator Tether™ to be of maximum usefulness for constellation spacecraft, it would be desirable to minmize the mass and the length of the tether. A lower added mass means more mass for revenue producing transponders, while a shorter tether length means a lower collision cross-section Area-Time Product during deorbit.

FIG. **6** shows a spacecraft **600** having a state vector **602** that causes the spacecraft to move across magnetic field lines **601**. Spacecraft **600** has a conductive tether **603** attached to it by tether deployer and control system **605**. The outer end of tether **603** is attached to tether end mass **607**. Spacecraft **600** also has an attached electron emitter means **613**.

In FIG. **6**, spacecraft **600** has a velocity and direction defined by state vector **602**. As spacecraft **600** moves it causes conductive tether **603** to cut magnetic field lines **601**. As this happens the distal end of the conductive tether collects electrons, shown as arrows **611**, from the space plasma. Electrons **611** move through the conductive tether **603**, are passed through a resistive load, not shown, in control system **605**, and are emitted back into the space plasma as electrons **615** from electron emitter **613**. This produces an electrodynamic drag in the direction shown by arrow **609**.

As is discussed in detail in the electrodynamic drag analysis below, especially in that sections of the analysis titled "Optimization of Tether Angle", the maximum electrodynamic drag of the tether is achieved when the angle, shown as the Greek letter τ in FIG. **6**, is 35.26 degrees, trailing, to the direction of the magnetic field lines. This angle may be maintained by a feedback control circuit that maximizes the electrodynamic drag of the tether system, as is discussed in detail below. The tether structure **603** is a Hoytether having a length of about 2 to 5 kilometers. The use of the 35.26 degree angle to the magnetic field reduces the tether instability, allowing the use of a short tether which will have a small Area-Time-Product. This will minmize the possibility that the tether will impact another space object during its use.

In FIG. **7**, spacecraft **700** has a state vector **702** across magnetic field lines **704**. Conductive tether **706** is attached to spacecraft **700** by tether deployer and control system **708**. The distal end of tether **706** is attached to a tether end mass **710**. Spacecraft **700** has an electron emitter means **714**.

Functionally, electrons **712** flow from the space plasma into conductive tether **706**, are passed through a resistive load in control unit **708** and are emitted into the space plasma by electron emitter **714** as free electrons **716**. As is discussed in detail in the analysis below, this produces an electrodynamic drag on satellite **700**, which causes it to deorbit.

In FIG. **7**, spacecraft **700** is rotating with an angular velocity indicated by arrow **718**. This rotation causes a centrifugal force **720** to place tension on conductive tether **706**. This force **720** places tension on the tether **706** in a direction that counters tether instability. The Tether **706** may be at any angle to the magnetic field while the rotation of the tether-satellite system is producing this useful tension. FIG. **7** shows the angle to be 35.26 degrees, which is optimum, but any angle will work.

FIGS. **8***a* and **8***b* show a powered Terminator Tether™. In FIG. **8***a* the spacecraft **800** has a state vector **802** that causes it and its associated conductive tether **806** to move across magnetic field **804**. Tether **806** has an end mass **808** that is proximate a plasma contactor **810**. Just as was discussed in the embodiment of the present invention shown in FIG. **6** and FIG. **7**, an electric current moves through the circuit formed by the space plasma, the plasma contactor **810**, the conductive tether **806**, and the electron emitter **815**, thence back into the space plasma as electrons **816**. This creates an electrodynamic drag on the tether in the direction shown by arrow **818**.

In FIG. **8***b*, similar numbers indicate similar structures. In FIG. **8***b*, however, an electric power source, not shown, in spacecraft **800** provides electrons to conductive tether **806**. The electrons are emitted from the end **812** of the tether **806**. Electrons are collected to from the space plasma **814** by contactor **815**, thus completing the electric circuit. The result is an electrodynamic force on tether **806**, and therefore on spacecraft **800**, in the direction show by arrow **820**.

Spacecraft **800** in FIG. **8***b* may be rotated as is taught in the embodiment of the invention shown in FIG. **7**, above, to allow the control system to time the application of electric current to the tether **806** to cause force **820** to be exert force in any desired direction along the circle made by the rotating tether. This allows the state vector of the spacecraft to be modified to raise or lower the spacecraft's orbital altitude, or to otherwise usefully change its orbital elements.

FIG. **9** show an embodiment of the present invention wherein the conductive structure of a satellite is used as the tether. In FIG. **9**, a spacecraft **900** which has a state vector

901 and is moving across magnetic field **903**, has two attached solar panels, **902** and **904**. Solar panels **902** and **904** have conductive aluminum frames **908** and **906**, respectively. Frame **906** is electrically and mechanically connected to plasma contactor **912**. Frame **908** is electrically and mechanically connected to electron emitter **910**. As spacecraft **900** moves across magnetic field **903**, electrons from the space plasma **914** flow through contactor **912** and frame **906** to the body of spacecraft **900**, where the current flows through a resistive load, not shown, and then into frame **908** and electron emitter **910** to the space plasma **916**, thus completing the circuit. This creates an electrodynamic drag on spacecraft **900**. If the power output from solar panels **902** and **904** was directed to flow into the frames, **906** and **908**, then the electrodynamic interaction with the space plasma would cause a useful force to be impressed on spacecraft **900**, as was discussed in connection with FIG. **8** above. The spacecraft may be rotated and/or oriented to a desired angle with the magnetic field lines, as was also discussed above.

FIG. **10** shows an embodiment of the present invention wherein the plasma contactor and the resistive load are structurally part of the conductive tether. In FIG. **10** spacecraft **1000** has a state vector **1001** that causes it to pass through magnetic field **1003**. Spacecraft **1000** has a tether control and deployment system **1005** that is connected to a conductive tether **1007** having an end mass **1013**. A contactor portion **1015** of the conductive tether **1007** near end mass **1013** is adapted to contact the space plasma so as to receive or emit electrons. This may be the bare wire strands of a wide Hoytether, or it may be any other plasma contactor means that can be conveniently made electrically part of the Hoytether structure, such as points or metal fuzz. A second resistive portion **1009** of tether structure **1007** is adapted to be a resistive load. This may be done by making a portion of the tether structure from a material, such as nichrome steel wire, that has suitable electrical resistance The large surface area of the Hoytether provides an excellent radiator structure into the three degree Kelvin radiation sink of outer space.

FIG. **11** shows an alternative embodiment of the load resistance/radiator structure of the present invention. In FIG. **11**, a biline Hoytether **1002** is attached to its control and deployer system **1100** on a spacecraft, not shown, and to a tether end mass **1004**. A resistive load, **1006** is woven into the Hoytether structure, whereby this load **1006** and the section of the Hoytether **1002** into which it is woven act together as a thermal radiator allowing photons **1008** to radiate into the thermal sink of outer space.

The following detailed analysis of the present invention will help those skilled in the art to better understand and use the present invention.

Electrodynamic Drag Analysis:

The following is an optimization analysis of the electrodynamic drag produced by a conducting tether deployed from a host spacecraft that it is to deorbit. The force and torque diagram used in the analysis is shown in FIG. **12**, which shows the forces and torques on an upward deployed conducting tether due to the motion of the host spacecraft through the magnetic field of the Earth.

Physical Constants and Assumptions:

The analysis that follows will use the following physical constants and assumptions:

Newton's gravitational constant $G=6.67\times10^{-11}$ $m^3/kg\text{-}s^2$.

Mass of Earth $M_e=5.976\times10^{24}$ kg.

Radius of Earth near equator $R_e=6378$ km.

Assumed host spacecraft altitude h=622 km.

Assumed host spacecraft orbital radius a=7000 km.

Host spacecraft orbital velocity $w=\omega a=[GM_e/a]^{1/2}=7546$ m/s.

Vertical gravity gradient at spacecraft $2\Gamma=2GM_e/a^3=2.32\times10^{-6}\ s^{-2}$.

Centrifugal gradient at spacecraft $\omega^2=GM_e/a^3=1.16\times10^{-6}\ s^{-2}$.

Combined gradient at spacecraft $3\Gamma=3GM_e/a^3=3\omega^2=3.49\times10^{-6}\ s^{-2}$.

Magnetic field of Earth (tilted dipole approximation):

Magnitude $B_o=35\ \mu T=0.35$ gauss.

Angle between magnetic pole and spin pole 11.5°.

Field components at spacecraft with altitude a and angle β between radius vector of spacecraft and magnetic equatorial plane.

Horizontal $B_H=B_o(R_e/a)^3\cos\beta=26.5\ \mu T\cos\beta$.

Vertical $B_V=2B_o(R_e/a)^3\sin\beta=52.9\ \mu T\sin\beta$.

Electrodynamic Tether Constants and Assumptions:

The electrodynamic tether is assumed to be made of a conducting metal, and have a length L, density d, resistivity r, and cross-sectional area A that is constant along the length of the tether. If the tether is a single round wire of diameter D, then the cross-sectional area is $A=\pi D^2/4$. Because of the micrometeorite and space debris hazard, however, it is likely the tether will be made up of redundantly interconnected multiple lines whose individual cross-sectional areas add up to A. Given these assumptions, the tether mass is then $m_T=dLA$, while the end-to-end tether resistance is $R_T=rL/A=rdL^2/m_T$.

Specific Conductivity Parameter:

The choice of the metal conductor to be used in a space tether is determined by a combination of low resistivity (high conductivity) and low density, with cost, strength, and melting point as secondary considerations for certain applications. Copper has a resistivity r=17.0 nΩ-m, a density d=8933 kg/m, and a "specific conductivity" of 1/rd=6,585 $m^2/\Omega\text{-kg}$. Aluminum has a resistivity r=27.4 nΩ-m, which is significantly greater than that of copper, but it has a much lower density of $d=2700\ kg/m^3$. As a result, aluminum's "specific conductivity" of $1/rd=13{,}500\ m^2/\Omega\text{-kg}$ is twice the conductivity per unit mass of copper. Silver, because of its higher density and higher cost, is not competitive as an electrodynamic space tether even though its resistivity of 16.1 nΩ-m is slightly better than that of copper. An alternate candidate material would be beryllium, with a resistivity r=32.5 nΩ-m, density $d=1850\ kg/m^3$, and a "specific conductivity" of $1/rd=16{,}630\ m^2/\Omega\text{-kg}$, slightly better than that of the much cheaper aluminum. Beryllium also has a higher melting point at 1551 K than aluminum at 933 K, so some of its alloys may be a preferred material for some electrodynamic applications despite its higher materials cost. Unfortunately, despite decades of metallurgical research by the nuclear power industry, highly ductile alloys of beryllium have not been found, so it is difficult to pull beryllium into wire. As a result, because of its high specific conductivity, low cost, and ready availability in ductile wire form, it will be assumed for this analysis that the electrodynamic tether will be made of aluminum wire.

Typical Resistance Values:

To be economically competitive, the mass of the tether needs to be a small fraction of the mass of the host spacecraft it is required to deorbit. Since a typical constellation spacecraft has a mass of about 1000 kg, a typical Terminator Tether™ with a mass that is 2% of the host spacecraft mass would consist of a deployer/controller package with a mass $m_D=10$ kg, containing an aluminum tether with a mass $m_T=10$ kg with a volume of $LA=m_T/d=3.70\times10^{-3}\ m^3$. If this 10 kg of aluminum were formed into a tether with a length of $L=2$ km and a cross-sectional area of $A=1.85\ \text{mm}^2$, then the end-to-end resistance of the tether would be $R=rL/A=rdL^2/m_T=29.6\ \Omega$ A longer tether would have a proportionately smaller cross-sectional area and a higher resistance; for example, a 5 km long tether with the same mass would have a resistance of 185 Ω.

Orbit Inclination Assumption:

In order to make the remainder of the analysis mathematically tractable, it will be assumed that the orbit of the host spacecraft is circular and above the magnetic equator, so that the angle between the radius vector to the spacecraft and the magnetic equatorial plane is $\beta=0$ degrees. In this orbit, the velocity v of the spacecraft with respect to the magnetic field is the orbital velocity w less the rotational velocity of the magnetic field at the orbital radius a due to the once per day rotation of the Earth, or:

$$v=W-2\pi a/1\text{day}=(7546-509)\text{m/s}=7037\text{m/s}$$

This equation also shows why electrodynamic drag will not be useful for removing geostationary spacecraft from orbit. At the geostationary orbital radius of $a=42{,}200$ km, the relative velocity of the spacecraft and the rotating magnetic field of the Earth is zero.

With this assumption of an orbit above the magnetic equator, the vertical component of the Earth's magnetic field is zero and the horizontal component of the Earth's magnetic field is at right angles to both the local vertical and the direction of motion of the spacecraft. The total magnetic field seen by the host spacecraft and its Terminator Tether™ is then orthogonally horizontal and has the magnitude:

$$B=B_H=B_o[R_e/a]^3 \cos \beta=26.5\mu T.$$

Where for simplicity the subscript H will be dropped for the remainder of this analysis.

This orbit, with its inclination of 11.5° with respect to the spin equator, will not stay in the plane of the magnetic equator, but will vary ±11.5° above and below it as the Earth rotates, causing a variation in magnetic field strength of $\pm 0.5\ \mu T$, as well as a slight variation in angle. This 2% variation is negligible in terms of the other uncertainties in this analysis. It is not until the orbital inclination of the host spacecraft orbit reaches 60°, where $\cos 60°=0.5$, that there is a significant drop in the expected magnitude of the electrodynamic drag forces calculated in this analysis.

Electromagnetic Drag Effects in Polar Orbit:

In many medium Earth orbit communication satellite constellations, there are a significant number of spacecraft at high inclinations and in nearly polar orbits. The high inclination spacecraft, with inclinations between 60° and 78.5°, will all have orbits that stay between the magnetic poles. Although the amount of electrodynamic drag will be significantly less than that experienced by spacecraft with orbits at lower inclinations, the direction of the induced electric fields in the tether will always be in the proper direction. If the tether is vertically upward, the outer tip of the tether will be positively charged and the bare wire in the tether will pull electrons out of the surrounding space plasma, while the electron emitter at the host spacecraft end will eject the electrons back into the space plasma to complete the circuit.

For spacecraft in near polar orbits with inclinations between 78.5° and 90°, however, there will be much more drastic variations. First of all, for a spacecraft in a 90° orbit that happens to pass directly over the magnetic poles, there is no horizontal component of the magnetic field when it is passing over one of the magnetic poles, so no voltage is generated in the tether during that part of the orbit, while the horizontal component of the magnetic field near the magnetic equator, while strong in magnitude, is along the spacecraft velocity vector, so no voltage is generated in the tether in that part of the orbit either. As a result, there will be negligible electrodynamic drag experienced by the host spacecraft during that particular orbit. The Earth is rotating, however, and the magnetic pole is rotating with it. A few orbits later, the host spacecraft will be passing over the Earth's spin pole at a point where the horizontal component of the magnetic field is exactly at right angles to the direction of motion of the spacecraft, so the full voltage is generated in the tether. When passing over the spin pole, the spacecraft radius vector is at an angle of 11.5° from the magnetic pole and at an angle $\beta=78.5°$ away from the magnetic equatorial plane. With these assumptions, the magnitude of the horizontal component of the magnetic field at the Earth's spin pole is a respectable:

$$B=B_o[R_e/a]^3 \cos 78.5°=5.28\mu T$$

or 20% of the maximum value experiences by spacecraft orbiting above the magnetic equator. This value will drop slightly as the orbit continues, then build back up as the spacecraft passes over the opposite pole. As the Earth continues to rotate, bringing the magnetic pole again under the orbit, and the interaction of the tether with the horizontal component of the magnetic field again drops to zero. The average coupling of a tether to the Earth's magnetic field over all polar trajectories has been calculated to be 12.3 percent.

A problem experienced only by spacecraft with orbit inclinations greater than 78.5°:

The spacecraft will no longer be traveling from west to east with respect to the magnetic field axis, but will have a retrograde motion as it moves through the magnetic field. As a result, the voltage generated by the motion of the tether through the Earth's magnetic field will switch direction. The outer tip will be negatively charged and will attempt to collect ions, which is a much less efficient process than collecting electrons.

There are a number of solutions to this problem. The first is to increase the mass and length of the tether supplied to a spacecraft assigned to a polar orbit, so that higher voltages, currents, and drag are generated during the limited times the spacecraft is passing over the poles in the right direction. The second is to supply a tether with plasma contactors at both ends that can emit electrons from either end, allowing the current to flow either way, depending upon which direction the spacecraft is passing around the magnetic pole. The third is to utilize the first number of passes to torque the orbit of the spacecraft until the orbit inclination has been shifted below 60°, then turn on the electrodynamic drag full time to deorbit the spacecraft from this more favorable orbit inclination. This orbit torqueing maneuver is accomplished by activating the electrodynamic drag mechanism only when the magnetic field orientation is such that a strong out-of-plane component of force is created. This orbit torqueing maneuver can be augmented by switching to a propulsion mode, where power saved in the batteries during the drag force mode is pumped back into the tether when the magnetic field is in the opposite direction, applying electrodynamic propulsion to torque the orbit even further. With the tether at a large and stable trailing orientation, the coupling to the magnetic field can be significant to a vertical tether.

In summary, spacecraft in near-polar orbits might take longer to bring down, and might have to utilize specially designed Terminator Tethers™ that might cost and mass more than the simpler Terminator Tethers™ usable in lower inclination orbits, but a Terminator Tether™ can still remove a spacecraft from a polar orbit when desired.

The inventors now present a detailed analysis and optimization of a typical Terminator Tether™ attached to a typical host spacecraft in a typical low inclination orbit.

Electromotive Generation of Voltage and Current in the Tether:

When an object is moved at a velocity v through a magnetic field B, an electric field is generated in the frame of reference of the moving object given by:

$$E=v\times B=vB$$

where the magnetic field B of the Earth, being mostly tangent to the Earth's surface in the north-south direction, is at right angles to the velocity vector v of the spacecraft, assumed to be orbiting in a generally west-east direction. The direction of the electric field E will be at right angles to both v and B, or along the local vertical. It should be noted that this electric field exists in the moving frame of reference because a moving magnetic field creates an electric field. No object actually has to be there, but if it is, then the relative motion of the magnetic field of the Earth will not only apply magnetic forces to whatever material the object is made out of, but electric forces too.

Note also that the velocity used in this equation is the relative velocity between the object and the magnetic field. Because the Earth's magnetic field rotates with the Earth, the motion of the magnetic field must be subtracted from the orbital velocity of the object to obtain the relative velocity.

Voltage generation in a Conducting Tether:

If the moving object is a long conducting wire of length L, the electric field E, generated in the wire produces a voltage V between the opposite ends of the wire given by:

$$V=E\bullet L=EL\cos\tau=vBL\cos\tau$$

where τ is the angle between the length vector L of the tether and the electric field vector E, assumed to be in the vertical direction at right angles to the velocity vector v in the plane of FIG. **12** and the magnetic field vector B out of the plane of FIG. **12**. A typical value for the voltage level built up in a vertically oriented tether with length L=5 km and $\tau=0$, moving at a velocity of v=7037 m/s through the Earth's horizontal magnetic field of strength 26.5 μT, is 932 V, or 0.186 V/m. Spacecraft in higher inclination orbits would experience somewhat smaller electric fields. For calibration, the voltage measured between the ends of the 19.5 km long TSS-1R tether was 3500 V, or 0.175 V/m.

Contacting the Space Plasma:

Although a voltage will build up between the ends of the conducting tether, no current will flow unless the circuit is completed. The circuit cannot be completed with another wire, for it too will have a similar voltage generated in it by the moving magnetic field. Fortunately, empty space is not empty, and in near-Earth regions not too distant from the Earth's atmosphere there exists highly electrically conductive space plasma, kept partially ionized by radiation from the Sun. The electron and ion density varies from the dark to light side, with altitude, with season, with sunspot cycle, with contamination level, etc. but it typically varies from 10^{11} to 10^{13} electrons/cc.

Fortunately, it has been found that if a bare conductive surface such as the spherical Italian spacecraft in the TSS-1R experiment, or the long bare wire to be used in the ProSEDS experiment, or a multiline conducting wire Hoytape mesh, is charged to a few hundred volts, the bare conductor will readily pull electrons out of the space plasma. So all that is needed to complete a connection to the space plasma at the positively charged (upper) end of the tether is a sufficient large area of uninsulated conductor.

It is more difficult to eject electrons from a wire or to collect positive ions from the space plasma. Although it is conceivable that a very large area at the other end of the tether could collect enough ions to complete the circuit as was demonstrated during the TSS-1R mission when the Shuttle orbiter was found to be an adequate plasma contactor for over an amp of current, the present method chosen is to use an electron emitter of some sort, either a hot cathode, a plasma cathode or contactor, a field-emission device, or something similar. Once provisions have been made at both ends of the tether to allow the flow of electrons out of one end of the tether and into the other end, and the altitude of the host spacecraft is not too high, then there will be sufficient conductivity in the space plasma surrounding the host spacecraft to allow current to flow through the tether.

Current Flow In The Tether:

The amount of current I flowing through the tether depends upon the total resistance R in the circuit. This resistance will consist of three components, the effective resistance of the plasma, the resistance of the tether, calculated earlier as $R_T=rL/A=rdL^2/m_T$, and a control resistor R_C, which will be varied as needed to optimize the Terminator Tether™ performance. There will also need to be a parasitic load on the current in the form of a charging device to charge some batteries. The batteries in turn will be used to power the control and communication circuits, and drive the electron emitting devices at the negative end of the tether. A well-designed Terminator Tether™ will thus be completely self-powered, except for an initial charge in the batteries to provide electrical power for the deployment and startup procedure. For simplicity of analysis it will be assumed that this battery charging load, which absorbs power like a resistor, but which stores it and uses it later instead of dissipating it immediately as heat, is included in the control resistor R_c. Normally, this load would act as a "base resistance" below which the control resistor could not be lowered, but since the charging circuit can be turned off when desired, and operations continued without interruption using the power stored in the batteries, it will be assumed that the control resistor can be taken to near zero value in those circumstances where the space plasma conductivity is low, or the magnetic field is in the wrong orientation and the voltage being generated in the tether is not large. Under these circumstances, lowering the control resistor to near zero allows a much higher current to flow for a given generated voltage, thus increasing the power being dissipated in the tether and maintaining a high level of electrodynamic drag on the host spacecraft.

A properly designed Terminator Tether™ will have plenty of bare metal area for electron collection at the positive end, while the electron emitters at the other end are efficient in terms of emitting large electron currents at low voltages and therefore low powers, while at the same time the mass, length, and area of the conducting tether have been made such that the resistance of the tether is moderately high. Under these conditions, the effective resistance of the space plasma will be much less than the design resistance of the tether. To make the mathematics more tractable it will be assumed that the plasma resistance is can be neglected and that the voltage available to drive the tether is the full voltage generated by the moving magnetic field. Although voltage will be needed to power the electron emitter, whatever its form, it will be assumed that the required voltage and power will be supplied by the batteries. The batteries in turn will be powered by the battery charging circuit, whose effective resistance is included in the control resistor (except for those short periods when the plasma or magnetic field interactions are weak).

Given all these assumptions concerning the total resistance in the circuit, the current I flowing through the tether is then given by:

$$I=V/R=vBL\cos\tau/(R_C+rdL^2/m_T)$$

A typical current level can be estimated by assuming that the control resistance R_C should be about the same size as the tether resistance R_T, which for an aluminum tether with resistivity r=27.4 nΩ-m, density d=2700 kg/m^3, length L=5 km, and mass m_T=10 kg, is R_T=185 Ω, giving a total resistance, including the control resistance R_C, of R=370 Ω. Thus the current flowing though a tether of length L=5 km, generating a voltage of V=932 V, would be I=V/R=2.52 A.

Power Dissipation Analysis:

The induced current I flowing through the tether resistance R_T will generate heat in the wire, which will be radiated into space and lost. That radiated energy must come from somewhere. There is also power taken out of the current flow by the battery charging circuit and ultimately dissipated. In order to conform to energy conservation laws, this power and energy must come from a decrease in the total kinetic and potential energy of the host spacecraft, causing it to deorbit. Set forth below is a detailed, optimized force analysis which will calculate the drag force on the host spacecraft. In this section, by using some simplifying assumptions, it is possible to produce a general argument based on energy conservation laws, which will illustrate the broad scope of the present invention.

For this energy conservation analysis it will be assumed that the plasma resistance is small compared with the tether resistance, and that the control resistance is equal to the tether resistance:

$$R_C=R_T=rL/A=rdL^2/m_T$$

Assume that the ballast mass at the end of the tether is a large piece of the defunct host spacecraft, such as a solar panel, antenna, or battery pack, so that the gradient force is large and the tether is always oriented along the vertical so that the angle τ=0°. Also assume the spacecraft is in an orbit above the magnetic equator and thus is moving at right angles to the Earth's magnetic field, so that the angle between the orbital velocity vector and the magnetic field vector is 90°, and the electric field vector is in the vertical direction, aligned perfectly with the tether length vector. Under these ideal conditions, the voltage between the ends of the tether is given by:

$$V=E\bullet L=(v\times B)\bullet L=vBL$$

The current in the tether is then just:

$$I=V/(R_C+R_T)=vBm_T/2rdL$$

The power dissipated as ohmic heating in the tether is then given by:

$$P=IV=(vB)^2m_T/2rd$$

This equation shows the interesting result that the power dissipated does not depend upon the length or the area of the tether (within reason), but only the mass of the tether m_T, the resistivity r and density d of the tether material, and the velocity v of the conducting tether through the Earth's magnetic field B.

For a typical aluminum tether of mass m_T=10 kg, the power dissipated is an impressive P=2350 W. Even if only a small fraction of this power is dissipated in a real system, the kinetic energy of the host spacecraft would suffer a significant energy loss with time.

Orbital Energy Extraction Analysis:

The total energy U of a spacecraft of mass M in orbit around the Earth consists of two components, its positive orbital kinetic energy and its negative gravitational potential energy. If a circular orbit of altitude h and radius a=R_e+h is assumed, then the total energy of the spacecraft moving at a velocity w=$(GM_e/a)^{1/2}$ is:

$$U=+Mw^2/2-GMM_e/a=-GMM_e/2a$$

The system will be dissipating energy in the tether to decrease the energy U of the unwanted spacecraft from its relatively low negative value in a high Earth orbit to a greater negative value in a lower Earth orbit. To give a specific example, an unwanted spacecraft with a mass of M=1000 kg (a metric ton) in an orbit with an altitude of h=1000 km and a high orbital radius of a(H)=R_e+h=7371 km, then its (negative) total energy is:

$$U(H)=-GMM_e/2a(H)=-27.1\text{ GJ or }-27.1\text{ MJ/kg}$$

It is desired to lower the spacecraft to an orbit with an altitude just outside the atmosphere of h=200 km or a lower orbital radius of a(L)=R_e+h=6571 km, where atmospheric drag will finish the job. The total (negative) energy of a metric ton spacecraft at 200 km altitude is:

$$U(L)=-GMM_e/2a(L)=-30.4\text{ GJ}$$

Thus, the amount of energy needed to be dissipated in order to move the 1000 kg spacecraft from a 1000 km orbit with a total energy U(H)=−27.1 GJ down to a 200 km orbit with energy U(L)=−30.4 CJ is:

$$dU=U(H)-U(L)=3.3\text{ GJ.}$$

The decay time T of a metric ton spacecraft moving from a 1000 km altitude orbit to a 200 km altitude orbit with an energy difference of dU=3.3 GJ, when its energy is being dissipated at a power of P=2350 W by a typical aluminum tether massing just 10 kg or 1% the mass of the spacecraft, is found to be T=dU/P=16 days.

The actual decay time will be longer than this. If the electrodynamic drag force is very large, and becomes larger than the gravity gradient forces pulling on the ends of the tether, then the tether will tend to align itself along the magnetic field lines instead of across them, and the drag force will decrease because of the small angle between the conductor length and the magnetic field lines. The tether current will need to be controlled until the angle of the tether settles into an angle determined by the balance between these two forces. These electrodynamic torque vs. gradient torque dynamic interaction effects are discussed in the next section.

Force and Torque Balance Analysis:

It is now possible to calculate the forces and torques on the tether. It is also possible to use the fact that the electrodynamic and gravity forces and torques on the tether must balance each other out to calculate and teach some optimum values for some of the Terminator Tether™ parameters.

Electrodynamic Force and Torque:

As discussed above, both theory and experiment show that: provided the conducting tether is moved rapidly through the Earth's magnetic field in order to generate a voltage across it, and provided good contact is made with the space plasma, the conducting tether will have a current flowing through it. When a wire (moving or not) carrying a current I is embedded in a magnetic field B, there will be an electrodynatnic force F_E generated on each element of the wire. The electrodynamic force will be at right angles to the magnetic field vector and the length vector of the wire element, with a magnitude given by:

$$F_E = J \times B = ILB$$

where B is the horizontal component of the magnetic field, which is perpendicular to the assumed magnetic equator orbit plane, while the tether length vector L is assumed to lie in the orbit plane. If, as will be the case most of the time, the electron current is leaving the space plasma and entering the tether along the length of the tether, then IL needs to be replaced with an integral of the current along the length of the tether.

Note that the electrodynamic force amplitude or direction is not directly dependent on the motion of the tether through the Earth's magnetic field. The electrodynamic force would be the same if the tether were not moving and the current was being supplied by a battery. Since the current I is a function of the orbital velocity, however, there is a secondary dependence of the electrodynamic force magnitude on the orbital velocity, but not its direction. The electrodynamic force is always at right angles to the conductor, and stays at right angles to the conductor as the angle τ varies, as shown in FIG. **12**.

Assuming that the electrodynamic drag force is applied uniformly along the length of the tether, it is possible to make the simplifying assumption that the integrated force is effectively applied at right angles to the center of mass of the tether at the point L/2 as shown in FIG. **12**. The electrodynamic torque on the tether is then:

$$T_E = F_E L/2 = IBL^2/2 = vB^2L^3 \cos \tau/2(R_C + rdL^2/m_T) = vB^2L^3 \cos \tau/2R$$

Gravity Gradient Forces and Torques:

When a tether and its ballast end mass are deployed from a host spacecraft, the gravity gradient force field of the Earth, combined with the orbital centrifugal gradient force field, will cause the tether to deploy either up or down from the host spacecraft. The direction desired depends on which end of the tether is connected to the electron emitter. Normally, the electron emitter will be on the end attached to the host spacecraft, in which case the desired direction of deployment will be upward so that the induced voltage in the tether will produce an excess of electrons at the electron emitter end of the tether. The desired upward direction is chosen by having the deployer eject the ballast mass in the upward direction. Once the ballast mass has been started in that direction, the centrifugal force due to the orbital motion of the ballast mass will cause the ballast mass to continue to accelerate in the upward direction until it is brought to a halt by the full deployment of the tether.

If there were no electrodynamic or atmospheric drag, the equilibrium direction of the tether would be exactly along the vertical, since the combined gradient field is a maximum in that direction. Because a significant amount of electromagnetic drag is expected, the actual angle of the tether with respect to the local vertical will be at some angle τ, lagging behind the spacecraft motion in the plane of the orbit, as shown in FIG. **12**. In the following analysis shows that there is an optimum angle for τ that produces the largest electrodynamic drag force on the host spacecraft without producing tether instability.

The combined vertical gravity gradient and centrifugal gradient field 3Γ acting on the ballast mass m_B at the end of the tether of length L will produce a gradient force F_{GB} given by:

$$F_{GB} = -3_{\Gamma} m_B L \cos \tau$$

The strength of the force depends not only on the ballast mass m_B and the strength of the gradient field 3Γ, but also the component along the radial direction of the distance of the ballast mass from the center of mass, which is L cos τ. This force acts in the vertical direction along the radius vector leading from the ballast mass away from the center of the Earth. The amount of gradient force is not large. For a ballast mass of m_B=10 kg and a tether length of L=5 km, the gradient force is about 0.175 N.

As can be seen in FIG. **12**, the component of this gradient force that is at right angles to the tether, given by F_{GB} sin τ, will produce a torque T_{GB} on the tether that tends to restore the tether toward the vertical, lessening the angle τ.

$$T_{GB} = LF_{GB} \sin \tau = -3_{\Gamma} m_B L^2 \sin \tau \cos \tau$$

The tether mass m_T also contributes to the gradient force and torque. If it is assumed that the tether has a uniform cross section, then it is possible to replace the distributed mass of the tether with an equivalent point mass m_T placed at the center of mass of the tether, which is the point L/2 along the tether, and a distance L/2 cos τ in the radial direction. The gradient force due to the tether mass is then:

$$F_{GT} = -3/2_{\Gamma} m_T L \cos \tau$$

While the gradient torque is:

$$T_{GT} = -L/2F_{GT} \sin \tau = -3/4_{\Gamma} m_B L^2 \sin \tau \cos \tau$$

The total gradient torque attempting to restore the tether to its vertical orientation is then:

$$T_G = T_{GB} + T_{GT} = 3_{\Gamma}(m_B + m_T/4)L^2 \sin \tau \cos \tau$$

It is important to notice the variation of the total gravity gradient torque as the tether angle τ is varied. Since the gradient force is always in the radial or vertical direction, there is no torque on the tether when the tether is vertical, as is the case when there are no aerodynamic or electromagnetic drag forces. Once the drag forces become important and start to apply torque to the tether, increasing the tether angle τ, those drag torques causing an increase in tether angle τ will be opposed by a rising gradient torque which will attempt to decrease the tether angle. For small tether angles, the gradient torque increases first linearly with τ, then as sin τ, since cos τ is near unity for small τ, then at τ=45° the gradient torque reaches its maximum, where sin τ=cos τ=0.707 and sin τ cos τ=0.50. When this angle is reached, the tether is a point of catastrophic instability, for if there is a further increase in the electrodynamic drag force, causing the angle τ to become greater than 45°, the gradient torque, instead of growing stronger to counteract the increased drag torque, will become weaker and the tether angle will go rapidly to 90°.

To restore control to the tether angle if the instability occurs, it will be necessary to turn off the electrodynamic drag forces by shutting off the current flow through the tether. The τ=90° position for the tether and ballast mass is a gravitationally unstable orientation. After a time, slight fluctuations in the gravity field will allow the gradient force to slowly take over and restore the tether to the vertical orientation, which, unless it can be controlled in some way, is equally likely to be up or down. It would therefore be desirable to maintain control of the tether angle so as to avoid the tether angle getting into the region of instability.

Torque Balance on the Tether:

The angle τ of the tether is determined by a balance between the electrodynamic torque T_E attempting to increase the angle τ and the gradient torque T_G attempting to decrease the angle τ. Balance is achieved when the two torques are equal:

$$T_E=T_G=T_{GB}+T_{GT}$$

or:

$$vB^2L^3 \cos \tau/2R=3_{\Gamma}(m_B+m_T/4)L^2 \sin \tau \cos \tau$$

Simplifing and rearranging yields an equation giving us the angle τ at which torque balance occurs:

$$\tau=\arcsin[vB^2L/6_{\Gamma}(m_B+m_T/4)R]$$

The physical interpretation of this equation is that the maximum electrodynamic force that can be sustained on the tether is limited by the gradient force on the tether. It is possible to increase the electrodynamic force by decreasing the total resistance R of the tether (for example, by using a tether with a larger mass and a lower tether resistance), but if the tether resistance is too low, then the quantity in brackets becomes greater than unity and this equation has no solution, indicating that the tether has reached an angle where instability sets in.

To maintain control of the tether angle, it will be necessary to vary the control resistance of the tether to compensate for variations in magnetic field strength and direction, plasma density (which affects the plasma resistance), and other factors, and thereby maintain the tether at an intermediate angle where both the electrodynamic and gradient forces are at an appreciable level and balance each other.

Optimization of Tether Angle:

At first glance, it might seem that the optimum angle for the tether would be 45°, since at that angle the gradient torque is largest and therefore can counteract a larger electrodynamic drag force. However, since the 45° angle is the point where instability sets in, it is desirable to set the tether angle at some value below 45°. The optimum angle is that which maximizes the horizontal or drag component of the electrodynamic force. This optimum angle τ is derived from the equation for the horizontal component of the electrodynamic force, or the electrodynamic drag force, since it opposes the host spacecraft motion:

$$F_{ED}=F_E \cos \tau=6[m_B+m_T/4]\Gamma L \sin \tau \cos^2\tau$$

By setting the partial derivative$\square F_{ED}/\square\tau=0$ and solving, it is possible to calculate that the optimum angle for the tether that gives the maximum electrodynamic drag force F_{ED}, while still keeping the tether torques balanced and under control, is τ=arctan(0.707)=35.26°. With this angle selected and maintained by varying the control resistor R_C to compensate for variations in plasma contact resistance and variatins in the strength and direction of the Earth's magnetic field B seen at the spacecraft, the tether experience the maximum stable value for the electromagnetic drag force of:

$$F_{ED}(\max,\tau=35.26°)=2.31[m_B+m_T/4]\Gamma L$$

There are many ways to provide the sensing information needed to provide the feedback signals to the control resistor, but the simplest is to merely measure the drag acceleration on the host spacecraft with a set of accelerometers, and maximiize the force in the direction opposite to the host spacecraft motion. Another method would be to measure the current in the tether, and knowing the tether resistance and the amount of control resistance, calculate the power being extracted and maximize that value. Alternate methods would be to use an optical position sensor or GPS receivers at both ends of the tether to measure the angle of the tether or the position of the ballast mass with respect to the host spacecraft.

To make an estimate of the magnitude of drag force attainable, assume that a typical aluminum tether with a length of L=5 km, a tether mass of m_T=10 kg and a ballast mass of m_B=10 kg is being used. Then the maximum gradient force limited electrodynamic drag force is F_{ED}=0.167 N. The power being dissipated in the canoical tether at the angle τ, with $R_C=R_T=rdL^2/m_T=185\ \Omega$ is given by:

$$P=IR=[vBL \cos \tau]^2(R_C+rdL^2m_T)$$

which for an angle τ=35.26° results in a power dissipation of 1570 W. Thus, the thrust level per unit power obtained by the typical Terminator Tether™ would be about 0.106 N/kW. This number is comparable to the value of 0.148 N/kW estimated for the much heavier and longer TSS-1R tether.

Reconciliation of Energy and Force Analysis:

By a force and torque balance analysis an optimum angle for the tether has been discovered at which it is possible to obtain a maximum in the drag component of the electrodynamic force. There is also an additional component of the electrodynamic force, the component in the vertical direction, $F_{EV=FE}$ sin(τ), which is downward for an upwardly deployed tether. This component of force combines with the gravity force of the Earth to effectively allow the host spacecraft to orbit a little faster than normal for that orbital altitude. It does not contribute to the deorbiting of the host spacecraft. But since this vertical component of force is created by current running through the tether, and that current is creating heat and dissipating energy as it passes through the tether, there might be some concern that the force and torque balance analysis above does not conform to the law of conservation of energy.

The inventors will now show, in a very general manner, that no matter what the tether angle, the electrical power being dissipated in the tether is exactly equal to the power being lost by the slowing of the host spacecraft.

The "deorbit power" P_D that must be removed from a spacecraft moving at a velocity v when that motion is opposed by a drag force F_{ED} is:

$$P_D=v\bullet F_{ED}=vF_E \cos \tau=vILB \cos \tau=I[vBL \cos \tau]$$

But, since the voltage V induced across the tether of length L and tilt angle τ moving at a velocity v through a horizontal magnetic field B is

$$V=E\bullet L=EL \cos \tau=vBL \cos \tau$$

Therefore:

$$P_D=IV=P_E$$

And the deorbit power P_D extracted from the slowing of the spacecraft by the drag component of the electrodynamic force is always exactly equal to the electrical power P_E being dissipated as heat in the tether circuits, independent of the tether angle.

Optimization of Tether Mass Distribution:

If it is not possible to use a piece of the host spacecraft as ballast mass, then the mass of the ballast must be included in the Terminator Tether™ mass. It would be desirable to minimize the total Terminator Tether™ mass, since every kilogram saved means that another kilogram's worth of revenue-producing transponders can be added to the working payload of the host spacecraft. Given a total mass for the Terminator Tether™ and the mass of the deployer/controller unit, it is possible to optimize the mass distribution between the ballast mass and the tether mass to obtain a minimum total Terminator Tether™ mass. A well-designed Terminator Tether™ will also have most, if not all, of the deployer mass incorporated into the ballast mass.

Assume that the total Terminator Tether™ mass consists of the deployer/controller mass m_D, the tether mass m_T, and the ballast mass m_B, with $m_B > m_T > m_D$. Of the three mass components in the Terminator Tether™, two of them affect the electrodynamic drag performance. If it is assumed that the ballast mass is a factor X larger than the tether mass, or $m_B = Xm_T$, the maxinum drag force that can be obtained is now:

$$F_{ED}(\max)=2.31m_T(X+0.25)\Gamma L$$

If it is assumed that the control resistor has been adjusted so that this maximum value for the electrodynamic drag force is maintained as the motion of the spacecraft along its orbit moves the spacecraft into regions with different magnetic field strengths and plasma densities, then for the angle $\tau=35.26°$, $\cos(35.26°)=0.817$, and the maximum electrodynamic drag force in terms of the electrodynamic parameters will be:

$$0.817vB^2L^2/(R_C+rdL^2/m_T)=F_{ED}(\max)=2.31m_T(X+0.25)\Gamma L$$

or canceling out terms and rearranging:

$$(X+0.25)=0.353vB^2L/\Gamma m_T(R_C+rdL^2/m_T)$$

It is now possible to make the further simplifying assumption that to maintain control of the tether, the control resistor needs to be roughly the same size as the tether resistance or $R_C \approx rdL^2/m_T$. Using this assumption produces an equation for the optimum value for the ratio X of the ballast mass to the tether mass:

$$\begin{aligned} X = vB^2/\Gamma rdL - 0.25 &= -0.25 + \frac{vB^2}{12\sin\gamma\cos\gamma\Gamma rdL} \\ &= -0.25\frac{\Lambda}{L} \end{aligned}$$

Where Λ is the "effective electrodynamic length".

If the tether is short, so that L is small, this equation indicates that the ballast mass must be increased to increase the gradient force, since it is the gradient force which determines the upper limit to the amount of electrodynamic drag force that can be generated without losing control of the tether.

Assuming the usual values for the Earth's magnetic and gradient fields, the velocity of the host spacecraft through the magnetic field, and the resistivity and density of aluminum, this equation becomes:

$$X=10.9/L-0.25$$

where L is in kilometers.

For a typical tether of length L=5 km, X=1.93. If the total mass for the Terminator Tether™ is 20 kg, or 2% of the host spacecraft mass, and the mass of the deployer is 10 kg, then the remaining 10 kg should be distributed so that 6.59 kg is in the ballast mass while 3.41 kg is in tether mass.

Optimization of Tether Length:

If the ballast mass consists of a piece of the host spacecraft, then the mass of the ballast does not have to be considered in the optimization of the Tether system. In this case, the optimum distribution of the Tether mass is to put as much mass as possible into the tether, with a minimum in the deployer/controller package. Under this assumption, the optimum length of the tether is determined by the desire to keep the Area-Time Product of the host spacecraft plus Tether to a minimum.

In a long tether of length L, the effective "collision" cross-sectional area is not the area of the tether, but the larger area produced by multiplying the length of the tether by sum of the width of the tether plus the width of the "target" spacecraft that would be damaged by the tether hitting it. Thus, to decrease the "area" portion of the Area-Time Product, it would be desirable to shorten the tether, making it thicker, and perhaps slightly wider, at the same time, thus keeping the same tether mass and electron collection area, and thereby maintaining the drag force and keeping the decay time at the same level. The result will be a shortening of the Area-Time Product.

If the tether is shortened too much, however, the smaller voltage generated across the shorter tether will leave less voltage margin for the operation of the plasma contactors and the battery recharge system. Since the maximum voltage that can be generated is about 200 V/km, and typical plasma contactors and battery, chargers take 25–100 V to operate, a minimum length for a Tether would be roughly 2 km. Host spacecraft operating in polar orbits, where the conditions for voltage generation are not as good, may require a tether length of 5 km or more.

Since many watts of heat power will be dissipated in the control resistor, means must usually be provided to radiate the heat away into space. One low-mass method of accomplishing this is to make the control resistor (or resistors) in the form of a long, electrically insulated, high resistivity wire similar to those used in electric blankets, but designed to operate at a higher temperature, and during the fabrication of the electrodynamic tether, incorporate the high resistivity wire (or wires) into the end of the tether closest to the control circuit by weaving or braiding the insulated high resistivity wire in with the uninsulated aluminum wire of the electrodynamic tether. The surface area of a long wire is very large, so in this extended wire configuration, exposed to the space all around it, the hot control resistor wire can self-radiate its power into cold space without incurring the mass penalty of a separate radiating surface.

Implementation:

The basic optimum structure for a Terminator Tether™ would be one of the many types of Hoytethers. A multiline (6–12 primary line) Hoytape™ will provide the largest contact area with the plasma, since both sides of the tape would be able to pass current to the plasma. If the spacing between the primary lines is chosen to be larger than twice the Debye length of the plasma, then the effective current collection area per unit length of the Hoytape is proportional to the width of the Hoytape mesh, not the diameter of the wires in the mesh. Thus, a Hoytape not only provides an assured longer life for the Terminator Tether™, but very short lengths will also provide a very large current collection areas.

The deployer for the tether can deploy the Terminator Tether™ either down or up or both. The deployer can stay attached to the spacecraft as was done in the SEDS missions, or perhaps a better alternative would have the deployer ejected from the spacecraft, with one end of the tether still attached to the spacecraft, reeling out tether as it leaves. The empty deployer would then act as a ballast mass at the end of the Terminator Tether™, which would improve the performance.

The "Remora Remover"

In addition to attaching Terminator Tethers to spacecraft before launch, it is possible to consider a missile-like application. This "Remora Remover" missile would use a Terminator Tether™ carried by a seeker missile similar to the small "hit-to-kill" missiles developed by the Space Defense Initiative Office that deployed a net loaded with oriented metal rods. The Remora Remover missile would hunt down a spacecraft that needs to be removed from space, but instead of hitting the spacecraft, the missile would be programmed to rendezvous with the spacecraft and attach itself to the host spacecraft using a hooked net, harpoon, or adhesive "sucker". The Remora Remover missile would then deploy the Terminator Tether™, which would bring down both the spacecraft and the missile.

The inventors have presented two analyses, backed up with data obtained from space flight experiments. One analysis was based on generalized energy conservation laws while the other analysis use force and torque balance arguments. Both analyses show that optimized aluminum wire tethers 2 to 5 km in length and massing just 1% to 5% of the mass of the host spacecraft can deorbit the host spacecraft in the order of a few weeks, thus mitigating the long-lived orbital debris hazard created by a constellation spacecraft after their end-of-life.

Power Augmented Operation of the Tether:

It is well known in the aerospace literature that if a spacecraft has a power supply and a conducting tether hanging from it, and the spacecraft is in an orbit or trajectory that takes it near a body, such as the Earth or Jupiter, which has both a magnetic field and a region of moderate density electron-ion plasma, and electrical current is pumped from the power supply through the tether and back through the plasma, that the current flowing through the tether will interact with the magnetic field of the body, producing forces on the tether and thence on the spacecraft, changing its orbit or trajectory. These forces can be used to increase or decrease the spacecraft altitude and/or inclination. The amount of altitude or inclination change is proportional to the ratio of the power available from the power supply divided by the mass of the spacecraft and varies with altitude. The unpowered Terminator Tether™ is a simple example of such a system, in which only altitude decrease is possible, although small amounts of both inclination increase or decrease are possible at the same time. Some typical references to this prior art are: Les Johnson, "Propulsive Small Expendable Deployer System Mission (ProSEDS)", Proceedings of the OAST 8^{th} Advanced Propulsion Workshop, JPL, Pasadena, Calif., 20–22 May 1997; and Les Johnson, Joe Carroll, Robert D. Estes, Enrico Lorenzini, Brian Gilchrist, Manuel Martinez-Sanchez, Juan Sanmartin, and Irwin Vas, "Electrodynamic Tethers for Reboost of the International Space Station and Spacecraft Propulsion, AIAA Paper 1996.

Since the Terminator Tether™ of the invention is normally associated with a satellite that has a power supply in the form of a solar panel combined with a storage battery, the Terminator Tether™ can be operated in the "powered propulsion" mode if desired. Such a mode would be useful when attempting to avoid a collision between the Terminator Tether™ and another spacecraft. In such cases, the power from the solar panel, augmented by the power stored in the battery, can be used to temporarily operate the Terminator Tether™ in the propulsion mode instead of the normal drag mode. This would enable to Terminator Tether™ to raise its altitude and/or increase or decrease its inclination to avoid a collision.

In addition, the Terminator Tether™ could be operated in the "power-augmented drag" mode. In this mode, there will be a current induced in the tether by the motion of the spacecraft through the magnetic field, which will cause a drag force on the spacecraft. This induced current would then be augmented by additional current in the same direction generated by the solar panel and the storage batteries in the power supply. The increased current will cause an increased drag force. If there is a significant vertical component of the magnetic field there will also be an increased force normal to the orbital plane, which will cause an increased rate of change of inclination.

When the Terminator Tether™ is operated in the "powered propulsion" or "power-augmented drag" mode, the conditions for stable optimum operation will be essentially the same as in the "unpowered drag" mode. The reason the conditions stay the same is that the maximum tether force than can be effectively utilized is limited by the strength of the gradient force, which has not changed, since the length and mass of the tether and the ballast mass has not changed for these different modes of operation. As a result the optimum operational angle for the tether is still 35.26 degrees, and the optimum ratio of ballast mass to tether mass for different tether lengths and tether material is still determined by the analysis of the invention as is set forth above.

In the analysis given above, where the optimum tether angle was found, the tether was assumed to be in the plane of the orbit and lagging behind the spacecraft motion, since in the "unpowered drag" mode, that would be its normal position, although if the component of the magnetic field along the orbit were high, there would be some tilt of the tether out of the plane of the orbit, producing a force tending to change the inclination of the orbit. In either of the "powered" modes of operation of the Terminator Tether™, however, the tilt of the tether could be forward toward the motion of the spacecraft or strongly tilted to one side or the other of the orbital plane. In all these cases, if the electrodynamic force is allowed to become too large, and the tether angle exceeds 45 degrees, the restoring force of the gradient field will drop off and the tether angle will go unstable. As a result, the optimum angle for the tether that will give the maximum stable force, whether it is a maximum drag force, and maximum propulsion force, or a maximum inclination change force, will be 35.26 degrees, and the optimum ratio for the mass of the tether versus the mass of the ballast will be the same as for the unpowered drag case.

The analysis that gave the optimum angle as 35.26 degrees assumed that the tether would be oriented like a rigid rotor. In reality, variations in forces along the tether will probably cause the tether to hang in a slightly curved shape, where the optimum angle may not be exactly 35.26 degrees from the local vertical. The optimum angle of the tether as it leaves the host spacecraft in such a case is where the drag force is largest.

The present invention is discussed in this disclosure in terms of its space applications as a Terminator Tether™ useful for the removal of unwanted satellites. It should be understood, however, that the present invention is useful in any application where a space object can use a conductive tether to produce electrodynamic force through interaction with a magnetic field. The invention, therefore, should be limited not by this description, but only by the appended claims and their equivalents.

What is claimed is:

1. A method of operating a conductive tether attached to a space object, said conductive tether being oriented at an angle to magnetic field lines of an external magnetic field and said conductive tether moving across the magnetic field lines of said external magnetic field at said angle to producing an electric current in said conducting tether and a resulting electrodynamic force acting on said tether and said attached space object comprising,

Controlling the amount of electric current flowing in said conducting tether to vary the angle between the conductive tether the field lines of the external magnetic field and the electrodynamic force acting on said tether and attached space object.

2. A method as in claim **1** wherein said angle is less than 45 degrees.

3. A method as in claim **1** wherein said angle is 35.26 degrees.

4. A method as in claim **1** wherein said angle is controlled to average 35.26 degrees over time.

5. A method as in claim **1** wherein said angle is controlled to average 35.26 degrees over the length of the tether.

6. A method as in claim **1** wherein the space object and the tether connected to it are rotated about their center of mass while the conductive tether interacts with the external magnetic field.

7. A method as in claim **1** wherein the angle of the conductive tether to the external magnetic field is controlled by sensing a measurable parameter of the space object/conductive tether system.

8. A method as in claim **7** wherein the parameter is current flow in the conductive tether.

9. A method as in claim **7** wherein the parameter is the electrical power dissipated in the conductive tether and the current control system.

10. A method as in claim **7** wherein the parameter is the relative position of the space object and the position of the far end tip of the tether.

11. A method as in claim **7** wherein the parameter is the acceleration of the space object.

12. A method as in claim **6** wherein the parameter is the state vector of the space object as measured by the Global Positioning System.

13. A method as in claim **1** including the step of applying electric power to the conductive tether to change the state vector of the space object.

14. A method of operating a conductive tether attached to a space object, said conductive tether being oriented at an angle to the local vertical between said space object and a celestial body having a magnetic field having magnetic field lines external to said conductive tether; said conductive tether moving across said magnetic field lines of said external magnetic field at an angle to the local vertical to produce an electric current in said conducting tether and a resulting electrodynamic force acting on said tether and said attached space object comprising,

Controlling the amount of electric current flowing in said conducting tether to vary the angle between the conductive tether the local vertical between said space object and said celestial body to vary the electrodynamic force acting on said tether and attached space object.

15. A method as in claim **14** wherein said angle is less than 45 degrees.

16. A method as in claim **14** wherein said angle is controlled to average 35.26 degrees over time.

17. A method as in claim **14** wherein the space object and the tether connected to it are rotated about their center of mass while the conductive tether interacts with the external magnetic field.

18. A method as in claim **14** wherein the angle of the conductive tether to the external magnetic field is controlled by sensing a measurable parameter of the space object/conductive tether system.

19. A method as in claim **18** wherein the parameter is current flow in the conductive tether.

20. A method as in claim **18** wherein the parameter is the acceleration of the space object caused by the electrodynamic force acting on the space object.

21. A method as in claim **18** wherein the parameter is the change in the state vector of the space object as measured by the Global Positioning System.

22. A method as in claim **14** including the step of applying electric power to the conductive tether to change the state vector of the space object.

23. A method as in claim **14** wherein the celestial body is the Earth and the magnetic field is the Earth's magnetic field.

24. A method as in claim **14** wherein the celestial body is the sun and the magnetic field is the Sun's magnetic field.

25. A method as in claim **14** wherein the magnetic field is the vector sum of the magnetic fields from all celestial bodies in the solar system.

26. A method as in claim **14** wherein the conductive tether is a Hoytether.

UNITED STATES PATENT OFFICE.

WILLIAM HENRY WARD, OF AUBURN, NEW YORK.

IMPROVEMENT IN COLLECTING ELECTRICITY FOR TELEGRAPHING, &c.

Specification forming part of Letters Patent No. 126,356, dated April 30, 1872.

I, WILLIAM HENRY WARD, of Auburn, in the county of Cayuga and State of New York, have invented an Electrical Tower for Accumulating Natural Electricity for Telegraphic Purposes, of which the following is a specification:

My invention consists of a tower for the purpose of receiving and imparting natural electricity, so as to be in constant contact with that upper stratum of electricity which surrounds the earth, by tapping which a never-failing supply is formed when brought into contact with the earth, as will be more fully explained hereinafter.

In the accompanying drawing, Figure 1 represents a side elevation of my improved electrical tower. Fig. 2 is a vertical central section of the upper part of the same. Figs. 3, 4, 5, 6, and 7 are detached views of several parts of the same.

The tower is constructed in three separate sections, a lower, a middle, and an upper one, and is placed on elevated mountain tops or peaks. The lower one, A, is a mere shell, having a door, *a*, and is constructed of any material suitable for the purpose. It is insulated from the middle portion B by means of a glass diaphragm, *c*, held between similar diaphragms of rubber, *d*, and of gutta-percha, *e*, by means of flanges *a'* and *b'*, formed on the upper end of the lower portion and the lower end of the middle portion of the tower respectively. These flanges are secured to each other by insulated bolts *f*. The middle portion B is provided with suitable openings or windows, G, having shutters or slats *g* pivoted in them, so that, by means of raising or lowering rods *h*, suitably connected to said shutters, the openings G may be shut or opened. A projecting roof, H, is formed on or secured to the middle portion B just over the openings G, and which serves the double purpose of protecting the said openings from the effects of the weather, such as rain or snow, and also for receiving the aerial electricity, which may be drawn from it by wires *i*, for land-line purposes. Above this roof H the middle portion of the tower is again insulated by diaphragms of glass, rubber, and gutta-percha from the upper portion I of the tower in the same manner as it is insulated from its lower portion. A circular plate, *j*, secured on the inside of this upper portion, bears a short tube, J, which is surrounded by the tube K of the ventilator L, from which latter the vane M extends; or the tube J may be held by rods extending from the side of the tower centrally. This ventilator is supported by a rod or shaft, *k*, firmly attached to the tube K, and having its lower bearing in a step, *l*, on a brace, *m*, crossing the middle portion B of the tower just above the openings G. This rod or shaft *k* is formed in two parts, insulated from each other, as shown at *k'*. On the lower portion of this shaft *k* is keyed or otherwise secured a sleeve, *n*, from which a horizontal serpentine cam-plate, *o*, shown in detail in Figs. 4 and 5, extends, over the rim of which the forked ends *p* of rods *h* seize, and which is so arranged relatively to the vane M and the shutters or slats *g* that the revolution of the vane by the wind will open the windward and close the leeward shutters or slats *g* and openings G by means of the rods *h*. Guide-plates or their equivalents N, provided with suitable openings, through which the rods *h* pass, keep the upper forked ends *h* of the latter in constant contact with the cam-plate *o*, which raises or lowers the rods, and consequently opens or closes the openings G as it revolves. A circular roof, O, extends from the tube K of the ventilator so as to cover and protect the open upper end of the tower. The upper portion I of the tower is provided with an insulating-tube, *p'*, through which a copper wire, *q*, enters the portion I of the tower, and is coiled around the tube J just under the tube K, which wire may connect that upper portion of the tower with any land line of wires. The upper portion I of the tower, as well as the tubes J K, may be constructed of zinc, while the vane may be made of zinc, copper, or any equivalent material, which, with the zinc and the moisture of the atmosphere, would form an electrical current. As the vane revolves it opens the openings to windward and closes those to leeward, thus helping to drive an aerial current of electricity into the insulated middle portion of the tower, which current passes upwardly through the upper portion of the tower and out through the ventilator or the top, which is swung around by the wind or aerial electrical current, thus forming a draught in addition to the closing of the shutters or openings to leeward, by means of which draught the electrical current is forced upwardly and out at the vane. The top portion of the tower is of course completely insulated from all below it, including the revolving central ventilator-shaft. As the middle portion of the tower allows the electrical current of atmosphere, wind, &c., to pass within, up, and out at the top it forms a continuous current, whereby the tower is receiving continually fresh and new supplies of electricity, which can be drawn from the projecting roof H by the wires *i* for the use of land lines of telegraphs or for other purposes, such as light, heat, &c. By the use of aerial electricity I entirely dispense with artificial batteries, forming my circuit merely by connecting the aerial current with the earth current. For instance, to bring Buenos Ayres, in South America, into direct connection with New York, the following plan would be pursued: One electrical tower is erected on Pike's Peak or any other suitable high mountain in North America, and another similar tower on some suitable peak of the Andes in South America. The former would, by means of land-lines, be connected directly with Denver, which place is again connected with all the prominent cities of the States. In a similar manner the southern tower is connected by land-lines with the prominent cities via Quito. New York telegraphs to the tower on Pike's Peak, and the operator having connected the land-line with the aerial current, the signals are transmitted through the aerial current to the tower in the Andes in South America; and from there—the land-lines being suitably connected with the aerial current—to Quito and Buenos Ayres. In this manner a message would be sent entirely by natural electricity in place of artificial. In the same manner a message may be sent across the ocean by having a high tower on each continent, each of which towers would have to be, of course, through land-lines connected with the earth to enable the ground current with the aerial current to form a circuit. Different towers may be erected on the different continents, and if they are all what is technically called hooked on—that is to say, connected to the earth—a signal given at one tower will be repeated at all the towers, they being connected with each other by the aerial current. If the earth-connection is severed, or the insulation with the tower destroyed, there is no power; but by insulating the tower and concentrating its force to a point, bringing the same corresponding effect from the earth current in connection, an exceedingly powerful electrical force is created.

Having described my invention, I claim—

1. A tower constructed so as to collect, hold, distribute, and utilize aerial currents of natural electricity for telegraphic and other purposes, essentially as described.

2. A tower for collecting aerial currents of natural electricity, constructed of three sections, insulated from each other and the earth, or their equivalents, substantially in the manner described.

3. In an electrical tower, the combination of the shutters or slats *g* with the ventilator-vane in such a manner that the vane, through suitable mechanism, always opens the shutters to windward and closes them to leeward, substantially as described.

4. In an electrical tower, the collecting, distributing, and protecting roof H, substantially as and for the purpose described.

5. The combination of the tube J and ventilator L with its vane M and the coiled wire or small cable *q*, substantially as and for the purpose set forth.

6. The combination of the insulated shaft *k* and rods *h* having forked upper ends *k'* with the shutters or blinds *g*, serpentine cam-plate *o*, and ventilator L, substantially as and for the purpose described.

The above specification of my improvement, being a tower for accumulating natural electricity for telegraphic purposes, signed this 29th day of June, A. D. 1871.

THE NORRIS PETERS CO., PHOTO-LITHO., WASHINGTON, D. C.

UNITED STATES PATENT OFFICE.

NIKOLA TESLA, OF NEW YORK, N. Y.

APPARATUS FOR TRANSMISSION OF ELECTRICAL ENERGY.

SPECIFICATION forming part of Letters Patent No. 649,621, dated May 15, 1900.

Original application filed September 2, 1897, Serial No. 650,343. Divided and this application filed February 19, 1900. Serial No. 5,780. (No model.)

To all whom it may concern:

Be it known that I, NIKOLA TESLA, a citizen of the United States, residing at the borough of Manhattan, in the city of New York, county and State of New York, have invented certain new and useful Improvements in Apparatus for the Transmission of Electrical Energy, of which the following is a specification, reference being had to the drawing accompanying and forming a part of the same.

This application is a division of an application filed by me on September 2, 1897, Serial No. 650,343, entitled "Systems of transmissions of electrical energy," and is based upon new and useful features and combinations of apparatus shown and described in said application for carrying out the method therein disclosed and claimed.

The invention which forms the subject of my present application comprises a transmitting coil or conductor in which electrical currents or oscillations are produced and which is arranged to cause such currents or oscillations to be propagated by conduction through the natural medium from one point to another remote therefrom and a receiving coil or conductor at such distant point adapted to be excited by the oscillations or currents propagated from the transmitter.

This apparatus is shown in the accompanying drawing, which is a diagrammatic illustration of the same.

A is a coil, generally of many turns and of a very large diameter, wound in spiral form either about a magnetic core or not, as may be desired. C is a second coil formed by a conductor of much larger size and smaller length wound around and in proximity to the coil A.

The apparatus at one point is used as a transmitter, the coil A in this case constituting a high-tension, secondary, and the coil C the primary, of much lower tension, of a transformer. In the circuit of the primary C is included a suitable source of current G. One terminal of the secondary A is at the center of the spiral coil, and from this terminal the current is led by a conductor B to a terminal D, preferably of large surface, formed or maintained by such means as a balloon at an elevation suitable for the purposes of transmission. The other terminal of the secondary A is connected to earth, and, if desired, to the primary also, in order that the latter may be at substantially the same potential as the adjacent portions of the secondary, thus insuring safety. At the receiving-station a transformer of similar construction is employed; but in this case the longer coil A′ constitutes the primary, and the shorter coil C′ the secondary, of the transformer. In the circuit of the latter are connected lamps L, motors M, or other devices for utilizing the current. The elevated terminal D′ connects with the center of the coil A′, and the other terminal of said coil is connected to earth and preferably, also, to the coil C′ for the reasons above stated.

The length of the thin wire coil in each transformer should be approximately one-quarter of the wave length of the electric disturbance in the circuit, this estimate being based on the velocity of propagation of the disturbance through the coil itself and the circuit with which it is designed to be used. By way of illustration, if the rate at which the current traverses the circuit including the coil be one hundred and eighty-five thousand miles per second then a frequency of nine hundred and twenty-five per second would maintain nine hundred and twenty-five stationary moves in a circuit one hundred and eighty-five thousand miles long and each wave would be two hundred miles in length.

For such a low frequency, which would be resorted to only when it is indispensable for the operation of motors of the ordinary kind under the conditions above assumed, I would use a secondary of fifty miles in length. By such an adjustment or proportioning of the length of wire in the secondary coil or coils the points of highest potential are made to coincide with the elevated terminals D D′, and it should be understood that whatever length be given to the wires this requirement should be complied with in order to obtain the best results.

It will be readily understood that when the above-prescribed relations exist the best conditions for resonance between the transmitting and receiving circuits are attained, and owing to the fact that the points of highest potential in the coils or conductors A A′ are coincident with the elevated terminals the maximum flow of current will take place in the two coils, and this, further, necessarily implies that the capacity and inductance in each of the circuits have such values as to secure the most perfect condition of synchronism with the impressed oscillations.

When the source of current G is in operation and produces rapidly pulsating or oscillating currents in the circuit of coil C, corresponding induced currents of very much higher potential are generated in the secondary coil A, and since the potential in the same gradually increases with the number of turns toward the center and the difference of potential between the adjacent turns is comparatively small a very high potential impracticable with ordinary coils may be successively obtained.

As the main object for which the apparatus is designed is to produce a current of excessively-high potential, this object is facilitated by using a primary current of very considerable frequency; but the frequency of the currents is in a large measure arbitrary, for if the potential be sufficiently high and the terminals of the coils be maintained at the proper elevation where the atmosphere is rarefied the stratum of air will serve as a conducting medium for the current produced and the latter will be transmitted through the air, with, it may be, even less resistance than through an ordinary conductor.

As to the elevation of the terminals D D′, it is obvious that this is a matter which will be determined by a number of things, as by the amount and quality of the work to be performed, by the condition of the atmosphere, and also by the character of the surrounding country. Thus if there be high mountains in the vicinity the terminals should be at a greater height, and generally they should always be at an altitude much greater than that of the highest objects near them. Since by the means described practically any potential that is desired may be produced, the currents through the air strata may be very small, thus reducing the loss in the air.

The apparatus at the receiving-station responds to the currents propagated from the transmitter in a manner which will be well understood from the foregoing description. The primary circuit of the receiver—that is, the thin wire coil A′—is excited by the currents propagated by conduction through the intervening natural medium from the transmitter, and these currents induce in the secondary coil C′ other currents which are utilized for operating the devices included in the circuit thereof.

Obviously the receiving-coils, transformers, or other apparatus may be movable—as, for instance, when they are carried by a vessel floating in the air or by a ship at sea. In the former case the connection of one terminal of the receiving apparatus to the ground might not be permanent, but might be intermittently or inductively established without departing from the spirit of my invention.

It is to be noted that the phenomenon here involved in the transmission of electrical energy is one of true conduction and is not to be confounded with the phenomena of electrical radiation which have heretofore been observed and which from the very nature and mode of propagation would render practically impossible the transmission of any appreciable amount of energy to such distances as are of practical importance.

What I now claim as my invention is—

1. The combination with a transmitting coil or conductor connected to ground and to an elevated terminal respectively, and means for producing therein electrical currents or oscillations, of a receiving coil or conductor similarly connected to ground and to an elevated terminal, at a distance from the transmitting-coil and adapted to be excited by currents caused to be propagated from the same by conduction through the intervening natural medium, a secondary conductor in inductive relation to the receiving-conductor and devices for utilizing the current in the circuit of said secondary conductor, as set forth.

2. The combination with a transmitting coil or conductor having its ends connected to ground and to an elevated terminal respectively, a primary coil in inductive relation thereto and a source of electrical oscillations in said primary circuit, of a receiving conductor or coil having its ends connected to ground and to an elevated terminal respectively and adapted to be excited by currents caused to be propagated from the transmitter through the natural medium and a secondary circuit in inductive relation to the receiving-circuit and receiving devices connected therewith, as set forth.

3. The combination with a transmitting instrument comprising a transformer having its secondary connected to ground and to an elevated terminal respectively, and means for impressing electrical oscillations upon its primary, of a receiving instrument comprising a transformer having its primary similarly connected to ground and to an elevated terminal, and a translating device connected with its secondary, the capacity and inductance of the two transformers having such values as to secure synchronism with the impressed oscillations, as set forth.

4. The combination with a transmitting instrument comprising an electrical transformer having its secondary connected to ground and to an elevated terminal respectively, and means for impressing electrical oscillations upon its primary, of a receiving instrument comprising a transformer having its primary similarly connected to ground and to an elevated terminal, and a translat-

ing device connected with its secondary, the capacity and inductance of the secondary of the transmitting and primary of the receiving instruments having such values as to secure synchronism with the impressed oscillations, as set forth.

5. The combination with a transmitting coil or conductor connected to ground and an elevated terminal respectively, and means for producing electrical currents or oscillations in the same, of a receiving coil or conductor similarly connected to ground and to an elevated terminal and synchronized with the transmitting coil or conductor, as set forth.

6. The combination with a transmitting instrument comprising an electrical transformer, having its secondary connected to ground and to an elevated terminal respectively, of a receiving instrument comprising a transformer, having its primary similarly connected to ground and to an elevated terminal, the receiving-coil being synchronized with that of the transmitter, as set forth.

7. The combination with a transmitting coil or conductor connected to ground and to an elevated terminal respectively, and means for producing electrical currents or oscillations in the same, of a receiving coil or conductor similarly connected to ground and to an elevated terminal, the said coil or coils having a length equal to one-quarter of the wave length of the disturbance propagated, as set forth.

8. The combination with a transmitting coil or conductor connected to ground and to an elevated terminal respectively, and adapted to cause the propagation of currents or oscillations by conduction through the natural medium, of a receiving-circuit similarly connected to ground and to an elevated terminal, and of a capacity and inductance such that its period of vibration is the same as that of the transmitter, as set forth.

9. The transmitting or receiving circuit herein described, connected to ground and an elevated terminal respectively, and arranged in such manner that the elevated terminal is charged to the maximum potential developed in the circuit, as set forth.

10. The combination with a transmitting coil or conductor connected to ground and to an elevated terminal respectively of a receiving-circuit having a period of vibration corresponding to that of the transmitting-circuit and similarly connected to ground and to an elevated terminal and so arranged that the elevated terminal is charged to the highest potential developed in the circuit, as set forth.

UNITED STATES PATENT OFFICE.

ANDOR PALENCSÁR, OF BUDA-PESTH, AUSTRIA-HUNGARY.

APPARATUS FOR COLLECTING ATMOSPHERIC ELECTRICITY.

SPECIFICATION forming part of Letters Patent No. 674,427, dated May 21, 1901.

Application filed July 10, 1900. Serial No. 23,102. (No model.)

To all whom it may concern:

Be it known that I, ANDOR PALENCSÁR, a subject of the King of Hungary, residing at Buda-Pesth, Austria-Hungary, have invented a certain new and useful Apparatus for Collecting Atmospherical Electricity, of which the following is a full, clear, and exact specification.

The present invention concerns an apparatus for collecting and driving or conducting atmospherical electricity which renders it practicable to obtain material quantities of the same in serviceable form.

The experiments made hitherto have been limited to deviating or conducting the electricity by simple lightning-rods without making allowance for the progress of the theory of atmospherical electricity. It is obvious that only extremely small quantities of electricity can be collected in this manner, and, moreover, it was obtained in a form which entirely precluded its utilization. It is evident that a source of electricity of irregular yield can only be utilized by means of accumulators and for charging accumulators only a current of constant potential can be employed. The potential of electricity derived or deviated by means of a lightning-rod varies within wide limits, and, moreover, it is so high that it cannot be used at all for charging accumulators. All these drawbacks are remedied by the present invention, by which the atmospheric electricity is obtained in larger quantities with as low and constant a potential as may be desired.

The idea underlying the invention is based on the modern theory of atmospheric electricity, according to which it is produced by the condensation of steam or aqueous vapors, and that the increase of potential is effected by the concentration of the small drops of water into larger ones, as the proportion of the surface of the drops to the volume of same is materially reduced thereby. According to this theory the water-droplets floating in the layers of air are considered as vehicles or carriers of the electricity, and a rational system of the deviation of the atmospheric electricity must derive it from the water-drops. This is attained by the present invention in the following manner: A collecting-body of as large a surface as possible is provided with sharp needles. This is moved in the higher layers of air, while being continually heated by a suitable heating device. Owing to the heat the water-drops immediately ambient to the collecting-body will be evaporated, their capacity is gradually reduced, while the potential of the charge grows until it reaches an infinite height with infinite smallness of the drops. It is readily apparent that the whole charge of the drops as soon as they have been evaporated will have passed to the collector or collecting-body, from which it can be conducted. For the purpose of replacing the evaporated drops, which have been deprived of their charge by new-charged drops, the collector is moved in relation to the ambient air.

One way of carrying out the invention is represented in diagram in the accompanying drawings, in which—

Figure 1 is a longitudinal section of the collecting-balloon. Fig. 2 shows the deviating and conversion device, and Fig. 3 a detail. Fig. 4 is a diagrammatic perspective view of a form of automatic regulator for the rheostatic machine.

The apparatus consists of a balloon having two walls and covered with a light wire net, preferably of aluminium wire, said net being studded with needles. Besides, the balloon carries the net 3, on which the ring 4, made of a solid but light material, (wood, cane, &c.,) is fixed. This ring carries the basket 6 by means of the cords or ropes 5. On a level with the ring 4 is the ring 7, which is kept spread by the blades or wings 9, which are journaled in a manner to rotate easily. The ring 7 is kept fixedly in position by the cords or ropes 8. The blades or wings consist of a frame covered with light material, and their rotation in either direction is limited by the stops or ledges 10. The blades or wings form advantageously an angle of sixty to seventy degrees with the vertical line.

All wire nets, ropes, rings, and blades or wings may be covered with small metal needles which are electrically connected with each other.

From the space 11, formed between the double walls of the balloon, the pipe 26 leads from the lowest point of the same to the serpentine 12, arranged in the basket 6, which in turn is

connected with the pipe 13, ending in the upper part of the space 11 between the two walls 12. The serpentine is heated by means of a suitable source of heat, whereby a warm current of gas or air circulates continually between the double walls of the balloon.

Under the basket the ball-bearing 14 is arranged in electrical connection with the wire nets, and its stud is electrically connected with the carefully-insulated light though sufficiently strong cable 15.

On the earth's surface is a winch 16, Fig. 2, by means of which the balloon can be made to ascend or descend as soon as the interior space of the balloon is filled with illuminating gas or hydrogen.

The end of the cable-core is soldered to a collector arranged upon and insulated from the axle of the winch, and the electricity is conducted from this collector by means of a sliding contact. The collecting of the electricity takes place by moving the balloon continuously up and down by means of the winch. In this movement the balloon is turned by means of the wings or blades 9, which are adapted to turn the balloon always in the same direction whether ascending or descending, as in the change from ascending into descending of the balloon, or vice versa, the blades are turned over by the aerial resistance, and thus impart the rotating motion to the balloon in the same direction. In order to avoid torsion of the cable, the ball-bearing 14 is provided. This up-and-down motion and rotating of the balloon accomplishes the purpose of bringing it into contact with as many water particles floating in the air as possible.

As the electricity conducted from the collector-wing 17 possesses a much too high and varying potential for making its direct application practicable, and as it is usual with an irregular source of electricity to first charge accumulators and to further utilize the easily-regulated current of the same only, it becomes necessary to seek to maintain the electricity conducted from the collector 17 for the charging of the accumulators at a constant potential and convert the potential to a much lower one; but as we deal in this case with a direct current ordinary converters cannot be used for this purpose. Moreover, the electricity possesses in this case a much too high potential, so that with the employment of ordinary converters the greatest part of the collected electricity would be lost again. The only practical method for this purpose is the converting by means of the Planté rheostatic machine, by which this high-voltage electricity can be transformed almost without any loss whatever. Thus the question of conversion would be solved, and only the question of maintenance of constant potential remains. This is obtained in the following manner: The rheostatic machine 18 or only a part of the plates is connected with an electrometer of any construction, the movable part of which closes a contact which eventually actuates an electromagnet which effects the switching or reversion of the rheostatic machine. After the switching of the rheostatic machine it is discharged, the potential falls to zero, (*nil*,) and the electrometer resumes its initial position, whereby the current of the electromagnet which effects the reversion is interrupted and the plates of the rheostatic machine are reconnected to potential. The machine is then ready for renewed charge and is again discharged when the determined potential is reached. This action is continually repeated as long as the apparatus is in operation.

A form of the automatic regulator for the rheostatic machine is represented in Fig. 4. 27 is the contact-cylinder of the rheostatic machine, on which, for clearness sake, only the contacts for the charging position of the condenser-plates are shown, while the contacts for the discharging position, which come into action after the contact-cylinder has been turned, are omitted. The coating of the condenser-plates is connected in electrical circuit with the stationary ball 29 and the movable ball 32 of the charge-meter 30. When the charge of the rheostatic machine rises, the ball 32, arranged on the one extremity of the lever 31, is repelled and at a certain stroke actuated by means of the fork 33, which is fastened on the ball 32, and by dipping into a mercury-cup it closes the circuit of the source of current 34. This current passes through the windings of the anchor or armature 35, fixed on the shaft of the contact-cylinder, and it also passes through the electromagnet 36. Thereby the contact-cylinder is turned by a certain angle and the rheostatic machine is thus reversed. Then if the tension decreases by discharge and the repulsion of the balls 29 32 declines so far that the contact is interrupted at 33 the spring 37 turns the contact-cylinder into its normal position and the rheostatic machine is again switched to tension. The regulation of the electrometer is effected by the adjustable weights 38 39. When larger quantities of electricity shall be derived or deviated, two rheostatic machines may operate alternately so, that while the one is being discharged the other can be charged. It is readily apparent that if the capacity of the rheostatic machine is not changed the switching or reversion by the electrometer will always take place at the same potential of the rheostatic machine, and as the number of plates, and hence the proportion of conversion, remains the same the current impulses derived or deviated from the rheostatic machine will also have the same potential.

The irregularities of the source of electricity change the interval of time in which the charges follow each other; but as long as the potential remains constant this has no injurious effect on the charge of the accumulators. The current derived. or deviated from the

rheostatic machine can be further transformed by an ordinary converter 21 22, and whenever it is sufficiently constant it can be utilized without the intervention of the accumulators. The converters can be connected or disconnected by means of the double switch 19 20 23.

24 and 25 are the conducting-wires, which run either directly to the place of consumption or to an accumulator-battery.

Having now described my invention, what I claim as new, and desire to secure by Letters Patent, is—

1. An apparatus for collecting atmospheric electricity comprising a collecting-body adapted to be kept in motion, heating means for said body, and a rheostatic machine and a converter connected with the said body electrically, substantially as described.

2. An apparatus for collecting atmospheric electricity for storage comprising a collecting-body adapted to be kept in motion in the ambient air, heating means for said body, a conductor leading from said body, a rheostatic machine connected with the said conductor, an electrometer connected with said rheostatic machine electrically, a contact controlled by the electrometer, and an electromagnet controlled by said contact, said electromagnet controlling the reversing of the rheostatic machine, substantially as described.

3. In combination, the balloon-like collecting-body, having the collecting-points, means for heating the interior space of said body, a conductor leading from the balloon-like body, and electrical devices for receiving the current therefrom, substantially as described.

4. In combination, the balloon-like collecting-body, means for turning the same constantly in one direction in both ascending and descending, conducting means leading from the balloon and electrical devices for receiving the current therefrom, substantially as described.

In witness whereof I have hereunto set my hand in presence of two witnesses.

UNITED STATES PATENT OFFICE.

NIKOLA TESLA, OF NEW YORK, N. Y.

APPARATUS FOR THE UTILIZATION OF RADIANT ENERGY.

SPECIFICATION forming part of Letters Patent No. 685,957, dated November 5, 1901.

Application filed March 21, 1901. Serial No. 52,153. (No model.)

To all whom it may concern:

Be it known that I, NIKOLA TESLA, a citizen of the United States, residing at the borough of Manhattan, in the city, county, and State of New York, have invented certain new and useful Improvements in Apparatus for the Utilization of Radiant Energy, of which the following is a specification, reference being had to the drawings accompanying and forming a part of the same.

It is well known that certain radiations—such as those of ultra-violet light, cathodic, Roentgen rays, or the like—possess the property of charging and discharging conductors of electricity, the discharge being particularly noticeable when the conductor upon which the rays impinge is negatively electrified. These radiations are generally considered to be ether vibrations of extremely small wave lengths, and in explanation of the phenomena noted it has been assumed by some authorities that they ionize or render conducting the atmosphere through which they are propagated. My own experiments and observations, however, lead me to conclusions more in accord with the theory heretofore advanced by me that sources of such radiant energy throw off with great velocity minute particles of matter which are strongly electrified, and therefore capable of charging an electrical conductor, or, even if not so, may at any rate discharge an electrified conductor either by carrying off bodily its charge or otherwise.

My present application is based upon a discovery which I have made that when rays or radiations of the above kind are permitted to fall upon an insulated conducting-body connected to one of the terminals of a condenser while the other terminal of the same is made by independent means to receive or to carry away electricity a current flows into the condenser so long as the insulated body is exposed to the rays, and under the conditions hereinafter specified an indefinite accumulation of electrical energy in the condenser takes place. This energy after a suitable time interval, during which the rays are allowed to act, may manifest itself in a powerful discharge, which may be utilized for the operation or control of mechanical or electrical devices or rendered useful in many other ways.

In applying my discovery I provide a condenser, preferably of considerable electrostatic capacity, and connect one of its terminals to an insulated metal plate or other conducting-body exposed to the rays or streams of radiant matter. It is very important, particularly in view of the fact that electrical energy is generally supplied at a very slow rate to the condenser, to construct the same with the greatest care. I use, by preference, the best quality of mica as dielectric, taking every possible precaution in insulating the armatures, so that the instrument may withstand great electrical pressures without leaking and may leave no perceptible electrification when discharging instantaneously. In practice I have found that the best results are obtained with condensers treated in the manner described in a patent granted to me February 23, 1897, No. 577,671. Obviously the above precautions should be the more rigorously observed the slower the rate of charging and the smaller the time interval during which the energy is allowed to accumulate in the condenser. The insulated plate or conducting-body should present as large a surface as practicable to the rays or streams of matter, I having ascertained that the amount of energy conveyed to it per unit of time is under otherwise identical conditions proportionate to the area exposed, or nearly so. Furthermore, the surface should be clean and preferably highly polished or amalgamated. The second terminal or armature of the condenser may be connected to one of the poles of a battery or other source of electricity or to any conducting body or object whatever of such properties or so conditioned that by its means electricity of the required sign will be supplied to the terminal. A simple way of supplying positive or negative electricity to the terminal is to connect the same either to an insulated conductor supported at some height in the atmosphere or to a grounded conductor, the former, as is well known, furnishing positive and the latter negative electricity. As the rays or supposed streams of matter generally convey a positive charge to the first condenser-terminal, which is connected to the plate or conductor above mentioned, I usually connect the second terminal of the condenser to the ground, this being the most convenient way of obtaining negative electricity, dispensing with the necessity of providing an artificial source. In order to utilize for any useful purpose the energy accumulated in the condenser, I furthermore connect to the terminals of the same a circuit including an instrument or apparatus which it is desired to operate and another instrument or device for alternately closing and opening the circuit. This latter may be any form of circuit-controller, with fixed or movable parts or electrodes, which may be actuated either by the stored energy or by independent means.

My discovery will be more fully understood from the following description and annexed drawings, to which reference is now made, and in which—

Figure 1 is a diagram showing the general arrangement of apparatus as usually employed. Fig. 2 is a similar diagram illustrating more in detail typical forms of the devices or elements used in practice, and Figs. 3 and 4 are diagrammatical representations of modified arrangements suitable for special purposes.

As illustrative of the manner in which the several parts or elements of the apparatus in one of its simplest forms are to be arranged and connected for useful operation, reference is made to Fig. 1, in which C is the condenser, P the insulated plate or conducting-body which is exposed to the rays, and P′ another plate or conductor which is grounded, all being joined in series, as shown. The terminals T T′ of the condenser are also connected to a circuit which includes a device R to be operated and a circuit-controlling device *d* of the character above referred to.

The apparatus being arranged as shown, it will be found that when the radiations of the sun or of any other source capable of producing the effects before described fall upon the plate P an accumulation of electrical energy in the condenser C will result. This phenomenon, I believe, is best explained as follows: The sun, as well as other sources of radiant energy, throws off minute particles of matter positively electrified, which, impinging upon the plate P, communicate continuously an electrical charge to the same. The opposite terminal of the condenser being connected to the ground, which may be considered as a vast reservoir of negative electricity, a feeble current flows continuously into the condenser, and inasmuch as these supposed particles are of an inconceivably small radius or curvature, and consequently charged to a relatively very high potential, this charging of the condenser may continue, as I have actually observed, almost indefinitely, even to the point of rupturing the dielectric. If the device *d* be of such character that it will operate to close the circuit in which it is included when the potential in the condenser has reached a certain magnitude, the accumulated charge will pass through the circuit, which also includes the receiver R, and operate the latter.

In illustration of a particular form of apparatus which may be used in carrying out my discovery I now refer to Fig. 2. In this figure, which in the general arrangement of the elements is identical to Fig. 1, the device *d* is shown as composed of two very thin conducting-plates *t t′*, placed in close proximity and very mobile, either by reason of extreme flexibility or owing to the character of their support. To improve their action, they should be inclosed in a receptacle, from which the air may be exhausted. The plates *t t′* are connected in series with a working circuit, including a suitable receiver, which in this case is shown as consisting of an electromagnet M, a movable armature *a*, a retractile spring *b*, and a ratchet-wheel *w*, provided with a spring-pawl *r*, which is pivoted to armature *a*, as illustrated. When the radiations of the sun or other radiant source fall upon plate P, a current flows into the condenser, as above explained, until the potential therein rises sufficiently to attract and bring into contact the two plates *t t′*, and thereby close the circuit connected to the two condenser-terminals. This permits a flow of current which energizes the magnet M, causing it to draw down the armature *a* and impart a partial rotation to the ratchet-wheel *w*. As the current ceases the armature is retracted by the spring *b*, without, however, moving the wheel *w*. With the stoppage of the current the plates *t t′* cease to be attracted and separate, thus restoring the circuit to its original condition.

Fig. 3 shows a modified form of apparatus used in connection with an artificial source of radiant energy, which in this instance may be an arc emitting copiously ultra-violet rays. A suitable reflector may be provided for concentrating and directing the radiations. A magnet R and circuit-controller *d* are arranged as in the previous figures; but in the present case the former instead of performing itself the whole work only serves the purpose of alternately opening and closing a local circuit, containing a source of current B and a receiving or translating device D. The controller *d*, if desired, may consist of two fixed electrodes separated by a minute air-gap or weak dielectric film, which breaks down more or less suddenly when a definite difference of potential is reached at the terminals of the condenser and returns to its original state upon the passage of the discharge.

Still another modification is shown in Fig. 4, in which the source S of radiant energy is a special form of Roentgen tube devised by me, having but one terminal *k*, generally of aluminium, in the form of half a sphere, with a plain polished surface on the front side, from which the streams are thrown off. It may be excited by attaching it to one of the terminals of any generator of sufficiently high electromotive force; but whatever apparatus be used it is important that the tube be exhausted to a high degree, as otherwise it might prove entirely ineffective. The working or discharge circuit connected to the terminals T T′ of the condenser includes in this case the primary *p* of a transformer and a circuit-controller comprising a fixed terminal or brush *t* and a movable terminal *t′* in the shape of a wheel, with conducting and insulating segments, which may be rotated at an arbitrary speed by any suitable means. In inductive relation to the primary wire or coil *p* is a secondary *s*, usually of a much greater number of turns, to the ends of which is connected a receiver R. The terminals of the condenser being connected, as indicated, one to an insulated plate P and the other to a grounded plate P′, when the tube S is excited rays or streams of matter are emitted from the same, which convey a positive charge to the plate P and condenser-terminal T, while terminal T′ is continuously receiving negative electricity from the plate P′. This, as before explained, results in an accumulation of electrical energy in the condenser, which goes on as long as the circuit including the primary *p* is interrupted. Whenever the circuit is closed owing to the rotation of the terminal *t′*, the stored energy is discharged through the primary *p*, this giving rise in the secondary *s* to induced currents, which operate the receiver R.

It is clear from what has been stated above that if the terminal T′ is connected to a plate supplying positive instead of negative electricity the rays should convey negative electricity to plate P. The source S may be any form of Roentgen or Lenard tube; but it is obvious from the theory of action that in order to be very effective the electrical impulses exciting it should be wholly or at least preponderatingly of one sign. If ordinary symmetrical alternating currents are employed, provision should be made for allowing the rays to fall upon the plate P only during those periods when they are productive of the desired result. Evidently if the radiations of the source be stopped or intercepted or their intensity varied in any manner, as by periodically interrupting or rythmically varying the current exciting the source, there will be corresponding changes in the action upon the receiver R, and thus signals may be transmitted and many other useful effects produced. Furthermore, it will be understood that any form of circuit-closer which will respond to or be set in operation when a predetermined amount of energy is stored in the condenser may be used in lieu of the device specifically described with reference to Fig. 2 and also that the special details of construction and arrangement of the several parts of the apparatus may be very greatly varied without departure from the invention.

Having described my invention, what I claim is—

1. An apparatus for utilizing radiant energy, comprising in combination a condenser, one armature of which is subjected to the action of rays or radiations, independent means for charging the other armature, a circuit and apparatus therein adapted to be operated or controlled by the discharge of the condenser, as set forth.

2. An apparatus for utilizing radiant energy, comprising in combination, a condenser, one armature of which is subjected to the action of rays or radiations, independent means for charging the other armature, a local circuit connected with the condenser-terminals, a circuit-controller therein and means adapted to be operated or controlled by the discharge of the condenser when the local circuit is closed, as set forth.

3. An apparatus for utilizing radiant energy, comprising in combination, a condenser, one terminal of which is subjected to the action of rays or radiations, independent means for charging the other armature, a local circuit connected with the condenser-terminals, a circuit-controller therein dependent for operation on a given rise of potential in the condenser, and devices operated by the discharge of the condenser when the local circuit is closed, as set forth.

4. An apparatus for utilizing radiant energy, comprising in combination, a condenser, one terminal of which is subjected to the action of rays or radiations, and the other of which is connected with the ground, a circuit and apparatus therein adapted to be operated by the discharge of the accumulated energy in the condenser, as set forth.

5. An apparatus for utilizing radiant energy, comprising in combination, a condenser, one terminal of which is subjected to the action of rays or radiations and the other of which is connected with the ground, a local circuit connected with the condenser-terminals, a circuit-controller therein and means adapted to be operated by the discharge of the condenser when the local circuit is closed, as set forth.

6. An apparatus for utilizing radiant energy, comprising in combination, a condenser, one terminal of which is subjected to the action of rays or radiations and the other of which is connected with the ground, a local circuit connected with the condenser-terminals, a circuit-controller therein adapted to be operated by a given rise of potential in the condenser, and devices operated by the discharge of the condenser when the local circuit is closed, as set forth.

7. An apparatus for utilizing radiant en-

ergy, comprising a condenser, having one terminal connected to earth and the other to an elevated conducting-plate, which is adapted to receive the rays from a distant source of radiant energy, a local circuit connected with the condenser-terminals, a receiver therein, and a circuit-controller therefor which is adapted to be operated by a given rise of potential in the condenser, as set forth.

APPARATUS FOR TRANSMITTING ELECTRICAL ENERGY.

1,119,732. Specification of Letters Patent. **Patented Dec. 1, 1914.**

Application filed January 18, 1902, Serial No. 90,245. Renewed May 4, 1907. Serial No. 371,817.

To all whom it may concern:

Be it known that I, Nikola Tesla, a citizen of the United States, residing in the borough of Manhattan, in the city, county, and State of New York, have invented certain new and useful Improvements in Apparatus for Transmitting Electrical Energy, of which the following is a specification, reference being had to the drawing accompanying and forming a part of the same.

In endeavoring to adapt currents or discharges of very high tension to various valuable uses, as the distribution of energy through wires from central plants to distant places of consumption, or the transmission of powerful disturbances to great distances, through the natural or non-artificial media, I have encountered difficulties in confining considerable amounts of electricity to the conductors and preventing its leakage over their supports, or its escape into the ambient air, which always takes place when the electric surface density reaches a certain value.

The intensity of the effect of a transmitting circuit with a free or elevated terminal is proportionate to the quantity of electricity displaced, which is determined by the product of the capacity of the circuit, the pressure, and the frequency of the currents employed. To produce an electrical movement of the required magnitude it is desirable to charge the terminal as highly as possible, for while a great quantity of electricity may also be displaced by a large capacity charged to low pressure, there are disadvantages met with in many cases when the former is made too large. The chief of these are due to the fact that an increase of the capacity entails a lowering of the frequency of the impulses or discharges and a diminution of the energy of vibration. This will be understood when it is borne in mind, that a circuit with a large capacity behaves as a slackspring, whereas one with a small capacity acts like a stiff spring, vibrating more vigorously. Therefore, in order to attain the highest possible frequency, which for certain purposes is advantageous and, apart from that, to develop the greatest energy in such a transmitting circuit, I employ a terminal of relatively small capacity, which I charge to as high a pressure as practicable. To accomplish this result I have found it imperative to so construct the elevated conductor, that its outer surface, on which the electrical charge chiefly accumulates, has itself a large radius of curvature, or is composed of separate elements which, irrespective of their own radius of curvature, are arranged in close proximity to each other and so, that the outside ideal surface enveloping them is of a large radius. Evidently, the smaller the radius of curvature the greater, for a given electric displacement, will be the surface-density and, consequently, the lower the limiting pressure to which the terminal may be charged without electricity escaping into the air. Such a terminal I secure to an insulating support entering more or less into its interior, and I likewise connect the circuit to it inside or, generally, at points where the electric density is small. This plan of constructing and supporting a highly charged conductor I have found to be of great practical importance, and it may be usefully applied in many ways.

Referring to the accompanying drawing, the figure is a view in elevation and part section of an improved free terminal and circuit of large surface with supporting structure and generating apparatus.

The terminal D consists of a suitably shaped metallic frame, in this case a ring of nearly circular cross section, which is covered with half spherical metal plates P P, thus constituting a very large conducting surface, smooth on all places where the electric charge principally accumulates. The frame is carried by a strong platform expressly provided for safety appliances, instruments of observation, etc., which in turn rests on insulating supports F F. These should penetrate far into the hollow space formed by the terminal, and if the electric density at the points where they are bolted to the frame is still considerable, they may be specially protected by conducting hoods as H.

A part of the improvements which form the subject of this specification, the transmitting circuit, in its general features, is identical with that described and claimed in my original Patents Nos. 645,576 and 649,621. The circuit comprises a coil A which is in close inductive relation with a primary C, and one end of which is connected to a ground-plate E, while its other end is led through a separate self-induction coil B and a metallic cylinder B′ to the terminal D.

The connection to the latter should always be made at, or near the center, in order to secure a symmetrical distribution of the current, as otherwise, when the frequency is very high and the flow of large volume, the performance of the apparatus might be impaired. The primary C may be excited in any desired manner, from a suitable source of currents G, which may be an alternator or condenser, the important requirement being that the resonant condition is established, that is to say, that the terminal D is charged to the maximum pressure developed in the circuit, as I have specified in my original patents before referred to. The adjustments should be made with particular care when the transmitter is one of great power, not only on account of economy, but also in order to avoid danger. I have shown that it is practicable to produce in a resonating circuit as E A B B′ D immense electrical activities, measured by tens and even hundreds of thousands of horse-power, and in such a case, if the points of maximum pressure should be shifted below the terminal D, along coil B, a ball of fire might break out and destroy the support F or anything else in the way. For the better appreciation of the nature of this danger it should be stated, that the destructive action may take place with inconceivable violence. This will cease to be surprising when it is borne in mind, that the entire energy accumulated in the excited circuit, instead of requiring, as under normal working conditions, one quarter of the period or more for its transformation from static to kinetic form, may spend itself in an incomparably smaller interval of time, at a rate of many millions of horse power. The accident is apt to occur when, the transmitting circuit being strongly excited, the impressed oscillations upon it are caused, in any manner more or less sudden, to be more rapid than the free oscillations. It is therefore advisable to begin the adjustments with feeble and somewhat slower impressed oscillations, strengthening and quickening them gradually, until the apparatus has been brought under perfect control. To increase the safety, I provide on a convenient place, preferably on terminal D, one or more elements or plates either of somewhat smaller radius of curvature or protruding more or less beyond the others (in which case they may be of larger radius of curvature) so that, should the pressure rise to a value, beyond which it is not desired to go, the powerful discharge may dart out there and lose itself harmlessly in the air. Such a plate, performing a function similar to that of a safety valve on a high pressure reservoir, is indicated at V.

Still further extending the principles underlying my invention, special reference is made to coil B and conductor B′. The latter is in the form of a cylinder with smooth or polished surface of a radius much larger than that of the half spherical elements P P, and widens out at the bottom into a hood H, which should be slotted to avoid loss by eddy currents and the purpose of which will be clear from the foregoing. The coil B is wound on a frame or drum D^1 of insulating material, with its turns close together. I have discovered that when so wound the effect of the small radius of curvature of the wire itself is overcome and the coil behaves as a conductor of large radius of curvature, corresponding to that of the drum. This feature is of considerable practical importance and is applicable not only in this special instance, but generally. For example, such plates at P P of terminal D, though preferably of large radius of curvature, need not be necessarily so, for provided only that the individual plates or elements of a high potential conductor or terminal are arranged in proximity to each other and with their outer boundaries along an ideal symmetrical enveloping surface of a large radius of curvature, the advantages of the invention will be more or less fully realized. The lower end of the coil B—which, if desired, may be extended up to the terminal D—should be somewhat below the uppermost turn of coil A. This, I find, lessens the tendency of the charge to break out from the wire connecting both and to pass along the support F′.

Having described my invention, I claim:

1. As a means for producing great electrical activities a resonant circuit having its outer conducting boundaries, which are charged to a high potential, arranged in surfaces of large radii of curvature so as to prevent leakage of the oscillating charge, substantially as set forth.

2. In apparatus for the transmission of electrical energy a circuit connected to ground and to an elevated terminal and having its outer conducting boundaries, which are subject to high tension, arranged in surfaces of large radii of curvature substantially as, and for the purpose described.

3. In a plant for the transmission of electrical energy without wires, in combination with a primary or exciting circuit a secondary connected to ground and to an elevated terminal and having its outer conducting boundaries, which are charged to a high potential, arranged in surfaces of large radii of curvature for the purpose of preventing leakage and loss of energy, substantially as set forth.

4. As a means for transmitting electrical energy to a distance through the natural media a grounded resonant circuit, comprising a part upon which oscillations are impressed and another for raising the ten-

sion, having its outer conducting boundaries on which a high tension charge accumulates arranged in surfaces of large radii of curvature, substantially as described.

5. The means for producing excessive electric potentials consisting of a primary exciting circuit and a resonant secondary having its outer conducting elements which are subject to high tension arranged in proximity to each other and in surfaces of large radii of curvature so as to prevent leakage of the charge and attendant lowering of potential, substantially as described.

6. A circuit comprising a part upon which oscillations are impressed and another part for raising the tension by resonance, the latter part being supported on places of low electric density and having its outermost conducting boundaries arranged in surfaces of large radii of curvature, as set forth.

7. In apparatus for the transmission of electrical energy without wires a grounded circuit the outer conducting elements of which have a great aggregate area and are arranged in surfaces of large radii of curvature so as to permit the storing of a high charge at a small electric density and prevent loss through leakage, substantially as described.

8. A wireless transmitter comprising in combination a source of oscillations as a condenser, a primary exciting circuit and a secondary grounded and elevated conductor the outer conducting boundaries of which are in proximity to each other and arranged in surfaces of large radii of curvature, substantially as described.

9. In apparatus for the transmission of electrical energy without wires an elevated conductor or antenna having its outer high potential conducting or capacity elements arranged in proximity to each other and in surfaces of large radii of curvature so as to overcome the effect of the small radius of curvature of the individual elements and leakage of the charge, as set forth.

10. A grounded resonant transmitting circuit having its outer conducting boundaries arranged in surfaces of large radii of curvature in combination with an elevated terminal of great surface supported at points of low electric density, substantially as described.

Filed May 12, 1959, Ser. No. 812,710
11 Claims. (Cl. 244—1)

This invention pertains generally to space vehicles and the like, and more particularly to a novel form of space vehicle and a system for maintaining such vehicle in flight or at a desired location in spaced-apart relationship with respect to a mother planet or the like.

The prior art affords many examples of apparatus adapted to be propelled in spaced-apart relationship with the earth, as well as systems for maintaining this relationship in opposition to the gravitational field thereof. Exemplary devices of this type are conventional aircraft (both jet and propeller driven) and the more modern un-manned or pilotless vehicles such as rocket-propelled missiles. However, the operation of each of these vehicles of the prior art necessitates the expenditure of a fuel carried by the vehicle. Further, while an orbital Earth satellite requires no applied energy in executing a given orbit, enormous quantities of fuel are consumed in launching the satellite into orbit. Also, where the satellite vehicle is designed for the subsequent correction of or other change in the orbital path, a fuel supply must be carried by the satellite in order to provide the desired corrective thrusts.

It is thus apparent that in each of these prior art vehicles a fuel supply must be carried thereby for local consumption in order to initiate, maintain or alter a given flight pattern, whether such pattern involves motion of the vehicle relative to the Earth or a substantially motionless hovering with respect thereto. It therefore follows that the maximum payload capabilities of such vehicles are limited by the fact that the vehicle must support the weight of the fuel carried thereby. Also, such vehicles are not naturally adapted to indefinitely long periods of continuous operation, since the fuel supply therein will eventually be exhausted, necessitating a return of the vehicle to a refueling base, or alternatively, an in-flight refueling process as is accomplished with some conventional aircraft.

The utility of a space vehicle or the like which is capable of sustained flight over an indefinitely long period of time without employing a local fuel supply is evident, and the applications therefor are numerous. For example, a vehicle capable of perpetual operation (except for mechanical failure) and stationed in space above the surface of the Earth, either within or without the atmosphere thereof, may perform alarm and surveillance tasks by radar techniques, along with guidance and protection of defense vehicles, and may simultaneously provide long-haul broadband communications. Systems of such vehicles or platforms may be established to provide radar and communication networks.

These desired operational characteristics are provided by the vehicle of the present invention, which vehicle is energized by means of transmitted microwave electromagnetic energy that is beamed toward the vehicle. The microwave energy incident upon the vehicle is converted into appropriate mechanical forces which produce the desired flight operation of the vehicle. The advantages attendant the utilization of microwave energy, in contrast to electromagnetic energy of other wavelengths, are readily apparent. Microwaves have been generally defined as radio waves whose wavelength is less than 30 centimeters, with a lower wavelength limit on the order of one millimeter or one centimeter sometimes being applied to what is called "the microwave region." The superiority of microwaves is due in part to the fact that

it is generally necessary to focus the transmitted energy so as to achieve a desirably high power density at a remote point or area with respect to a given generator or transmitter power level. In accordance with the laws of optics, the sharpness of the beam produced by an antenna varies as the ratio of antenna dimensions to the wavelength of the transmitted energy. Thus, for a given or desired power density or beam sharpness, a decrease in the wavelength of the transmitted energy permits a corresponding decrease in the dimensions of the antenna. From the standpoint of mechanical convenience, it is generally desirable to employ small antennas and other components, and it is therefore advantageous to employ energy of very short wavelength. In addition, the difficulties encountered in relatively long wave transmission as a result of natural and man-made interference or noise (which noise would interfere with the transmission of radar or communications intelligence via the microwave power beam) do not occur with any appreciable significance at microwave frequencies. Also, where the space vehicle is to be operated at an altitude above the ionosphere, long wave transmission will generally be reflected by the reflecting layers thereof, while microwaves pass through such layers substantially unaffected.

In view of the several advantages stated above, it might appear desirable to employ the shortest wavelength possible commensurate with the power-generating capabilities of the transmitter at the wavelength chosen. A lower limit is fixed, however, for the wavelength that may be used in a practical radiating system in view of the increasing losses due to absorption occurring in the atmosphere at wavelengths below five to ten centimeters. In the one to two centimeter region, there is a peak in absorption by water vapor, and even for dry air the absorption of electromagnetic energy increases very rapidly below one or two centimeters. It may thus be seen that microwaves in a region having the approximate bounds of two and thirty centimeters are readily adaptable to convenient radiation of energy to a remote point with small transmission loss, with the preferred wavelengths being of the order of five or ten centimeters in order to accomplish efficient focusing with a transmitting lens system of reasonable size without inflicting an intolerable power loss by absorption.

The key to the practical utilization of high-power electromagnetic beams for remote energization of space vehicles and the like is a device which will generate large amounts of power within this wavelength region. In addition, many applications of such high-power beams require such refinements as broad electronic bandwidth and low phase distortion, placing the additional requirement of sophisticated performance on the high-power generator. A device which currently satisfies the duel requirements of high power output and refined performance is the Amplitron tube, a relatively new type of crossed-field vacuum tube which may be used as a compact, highly efficient, broadband amplifier capable of handling high peak and average powers, and which generally comprises a circular but non-reentrant, dispersive network matched at both ends over the frequency region of interest, and a reentrant electron beam originating from a continuously-coated (or nearly so) cathode coaxial with the network, with a D.-C. potential being applied between the cathode and anode, and a magnetic field applied parallel to the axis of the cathode and transverse to the electric field between the anode and the cathode. For a more complete description of the Amplitron, reference may be had to my application Serial No. 706,812, filed January 2, 1958, for "Low Level Duplexer System," now United States Letters Patent No. 2,933,723, which issued April 19, 1960. Amplitrons currently available are capable of producing 15 or 20 kilowatts of average radio-frequency power in the neighborhood of ten centimeters in wavelength, and future models are expected to yield 500 kilowatts or more average power, with 50 megawatt peak power.

It is accordingly a primary object of this invention to provide a space vehicle or the like designed for an indefinitely long period of operation either in moving flight or at a selectable location with respect to the Earth or other mother planet, with energy necessary for such operation being supplied to such device in the form of microwave electormagnetic energy.

A further object of the invention is to provide a system for maintaining a space vehicle either in moving flight or at a selectable location with respect to a mother planet or the like in response to microwave electromagnetic energy transmitted from such mother planet to the vehicle.

In accordance with an exemplary embodiment of the present invention, this system for maintaining flight of the space vehicle includes means on the Earth or some other mother planet for radiating microwave energy in a beam directed toward and focused on the vehicle for substantially continuously supplying such vehicle with the power necessary for the operation thereof. The space vehicle of the invention has means associated therewith for receiving and converting incident microwave energy into appropriate forces applied to the vehicle to sustain flight. The received microwave energy may be directly converted into a flight-producing force as by an ion engine or the like, or the microwave energy may be subjected to a mesne conversion to heat. In the latter case, means are provided for applying the heat converted to a suitable fluid medium which is expanded thereby to perform the work necessary to propel or sustain the vehicle.

In one preferred form of the apparatus of the invention, a plurality of thrust-providing engines are mounted for rotary movement about a substantially vertical common axis along which the beam of energy is normally transmitted, with suitable airfoil means being mounted for movement with such engines to provide the lifting force necessary to maintain flight of such vehicle. Means are provided for apportioning the received energy between the several engines in such manner as to selectively energize the engines to maintain the vehicle centered on the transmitted beam.

In an alternative form of the apparatus of this invention, a plurality of thrust-providing engines are symmetrically positioned with respect to the vertical central axis of the vehicle along which the beam of energy is normally transmitted. Means are provided for distributing the received energy between the engines so as to differentially energize the engines to apply corrective forces to the vehicle upon the occurrence of angular or translational displacement of the axis thereof from the center line of the radiated beam.

With the above considerations and objects in mind, the invention itself will now be described in connection with a preferred embodiment thereof given by way of example and not of limitation, and with reference to the accompanying drawings, in which:

FIG. 1 is a perspective view of a preferred form of the apparatus of the present invention, schematically indicating the control system therefor;

FIG. 2 is a partial sectional view in elevation of the vehicle shown in FIG. 1, the section being taken substantially centrally of the vehicle;

FIG. 3 is a plan view of a portion of the apparatus of FIG. 1; and

FIG. 4 is a partial sectional view in elevation of an alternative form of the apparatus of this invention.

Referring now to FIG. 1, one preferred form of the vehicle of the present invention is indicated generally at **10**. As shown, the vehicle **10** is adapted to be maintained in flight or in hovering position with respect to the Earth or other mother planet **12** by means of energy transmitted to the vehicle as radiated microwave electromagnetic energy in beam form, as indicated by lobe **14** having center line **15**. A suitable transmitter **16** is provided for this purpose, along with a beam-forming transmitting antenna **18**. As will be appreciated by those skilled in the art, the representations of the transmitting equipment and microwave beam in FIG. 1 are highly diagrammatic in form, and the present invention is not limited to any particular transmitter or antenna assembly. As a practical matter, however, the reflector of the antenna assembly **18** is considerably larger than most of the reflectors of the prior art in order to focus a large amount of power at a high-altitude (e.g. 65,000 feet) space vehicle. In an exemplary embodiment, the antenna reflector is at least partially supported in a large bowl or other dug-out area on the Earth's surface so as to provide a convenient means of support therefor. Also, the antenna may actually comprise a large number of small horn and reflector assemblies. In addition, the transmitter **16** is capable of much greater power output than most of the prior art transmitters, and, as stated in the earlier paragraphs of this specification, the power-generating element of the transmitter is preferably an Amplitron tube in order to achieve sufficient power output.

The microwave energy that illuminates the vehicle **10** is intercepted by the under or concave side of the reflecting member **20**, the curvature of which is such that the energy received along a substantially straight line parallel to the central axis of the radiated beam of energy is reflected into an annular opening **22** in the frame member **24**. The latter frame member may preferably comprise a hollow waveguide for the received radio-frequency energy, and the energy applied thereto through the opening **22** is, in turn, applied to the several engines **26** connected thereto.

The means for maintaining flight or hovering conditions in the vehicle **10** include the several engines **26**, which effect a rotary motion of the vehicle frame in the direction shown by the arrows about a substantially vertical central axis normally coinciding with the center line of the transmitted beam **14** of microwave energy. Upon such rotary motion of the vehicle frame, a sustaining lift is provided by means of a plurality of airfoil members **28**, which may generally be in the form of the rotary wings of a helicopter or the like. It will be understood that only the basic elements of the vehicle **10** are shown in the drawing, and that other frame members and the like would normally be provided to support a payload of radar, communication or other similar equipment. In this connection, the beam **14** also provides a signal-information link between the ground station and the payload equipment on the vehicle.

FIG. 2 shows in somewhat greater detail the construction of the apparatus of FIG. 1, with the showing of FIG. 2 being taken along a vertical plane through one of the supporting airfoil members **28**. The construction and operation of the several thrust engines will not be discussed in detail herein, since a complete description of engines suitable for this purpose is provided in my application Serial Number 812,697, filed May 12, 1959, now United States Letters Patent No. 3,083,528, which issued April 2, 1963, and assigned to the assignee of the present application. As disclosed in such application, an exemplary embodiment of an engine suitable for use in the vehicle of the present application includes a heat-exchanging container means adapted to be energized by microwave energy to heat a gaseous medium therein and cause expansion of same to produce a jet stream for providing a propulsive thrust. In one preferred form of the invention, the container means comprises an electromagnetic waveguide of lossy characteristics which produces heat upon energization by suitable electromagnetic energy to raise the temperature of a gaseous medium passing therethrough. A member of stacked and closely-spaced electrically lossy plates is preferably mounted within the waveguide to serve as the main means for absorbing microwave energy and converting same into heat, as described in detail in the aforementioned copending application. The plurality of closely spaced plates form therebetween a series of narrow passages through which passes the gaseous medium which is to be heated thereby. The microwave energy employed is of sufficiently high frequency to produce a pronounced skin effect in the waveguide and associated heat-exchanger, so that the energy expended in creating heat in the steady state condition is effectively and quickly transferred to the gaseous medium in which the particular conductor exhibiting the skin effect is immersed. This latter feature is particularly advantageous in transient-state conditions with respect to the ability of the engine of this invention to provide almost instantaneous response to a change in the level of the applied microwave energy, since little or no time lag is involved in converting electromagnetic energy to heat and transferring it to the cooling gas. As is evident, the heated gas may be formed into a jet stream in order to provide propulsion, or a turbine may be driven thereby to provide a rotary shaft output for driving a propeller or the like.

As may be seen in FIG. 2, the engines 26 are supported from the rotary frame member 24 by means of suitable supporting members 30 which also serve as the means for transferring the microwave energy in the interior of the frame member 24 to the interior of the engines 26. Thus, each of the supporting members 30 must be adapted to act as a transmission line of short length for the radio-frequency energy employed. The particular curvature of the reflecting member 20 is chosen so as to effect the reflection of radiated energy indicated in FIG. 2, viz., the energy transmitted toward the vehicle reaches the reflector member 20 along substantially straight parallel paths as shown by the vertical dash-dot lines, and upon reflection all of the received energy is focused on the opening 22 in the frame member 24 so that it may be transferred into the several engines 26.

FIG. 3 shows that the direction of thrust produced by each of the engines 26 is not quite tangential to the circle of rotation thereof. As shown, the engines 26 are mounted at a small angle with respect to the periphery of the frame member 24, so that while the major portion of the thrust produced by each of the engines is tangential to such periphery, a small component thereof is directed away from the center of the vehicle. This construction is employed in order to provide a vehicle which is capable of a self-centering or beam riding operation, as will be more fully described below.

In the operation of the device thus far described, transmitter 16 generates a suitable microwave signal for transmission to the vehicle 10 by means of the radiating antenna 18. In the normal operation of the device, the reflecting member 20 will be centrally positioned in the radiated beam 14, and the energy of the beam will therefore be reflected in equal amounts toward all portions of the annular opening 22 in frame member 24. As a result, the three engines 26 will receive equal amounts of the radio-frequency energy, and normal operation is thereby effected, resulting in a rotary movement of the engines 26 and the frame member 24 about the central vertical axis of the vehicle 10. As mentioned above, such rotational movement of the frame member 24 produces a corresponding rotation of the airfoil members 28 to provide a vertical thrust for maintaining the vehicle 10 in flight or in a hovering position with respect to the mother planet 12.

In order to maintain the vehicle 10 in a desired location with respect to the center-line of the transmitted radio-frequency beam 14, viz., at a centered position with the vertical central axis of the vehicle coinciding with the center line of the transmitted beam, the shape of the concave reflecting surface of member 20 is chosen as described above to reflect energy of the beam 14 equally to the several engines 26 when the vehicle 10 is properly centered in the beam 14. Upon a lateral displacement of the vehicle 10 from the beam 14, one side of the reflecting surface 20 will be illuminated by more radiated energy than the opposite side, and the several engines 26 are thereupon differentially energized to provide corrective lateral forces to achieve recentering of the vehicle in the beam. It will be understood that the desired tolerance as to vehicle position and the lateral dimensions of the beam and the vehicle are so interrelated that a displacement beyond such tolerance will result in a significant degree of such differential energization. For example, if the vehicle 10 were to be displaced toward the right in FIG. 2, the left-hand portion of the reflecting member 20 would lie nearer the center of the beam 14, and the engine shown in FIG. 2 would thereupon receive a greater amount of energy than the other engines. Since the engine 26 of FIG. 2 (as well as each of the remaining engines of the vehicle) provides a component of thrust normal to the circle of rotation thereof and directed away from the center of the vehicle, such additional energization of the engine shown in FIG. 2 will provide a resultant lateral thrust toward the left in this figure. It is evident that the particular engine 26 shown in FIG. 2 will be in motion, and will therefore not remain at the position shown to continuously receive the major portion of the energy intercepted by reflector member 20. As each of the engines 26 passes through the azimuthal position of rotation opposite to the direction of lateral displacement of the vehicle 10 from the center of the beam 14, it then receives a greater energization than the remaining engines, and such differential energization of the several engines 26 continues with the rotational movement of such engines until the vehicle is once again centered in the beam 14. As will be appreciated by those skilled in the art, there must be a minimum lag in the transient response of each of the engines 26 in order to achieve the self-centering action. In this connection, the efficacy of the engine of my aforementioned copending application is evident. As stated above, the thermal time lag of this engine is minimal as a result of the fact that there is a significant skin effect in the microwave heat exchanger, and the transient-state heat changes are produced in intimate proximity to the fluid medium to be heated. As a result of the propinquity of the heat source (the shallow skin effect penetration of the heat-exchanging wall) and the sink (the fluid medium to be heated), such engines are able to respond almost instantaneously to a change in the power input, thus making the self-centering of vehicle 10 feasible.

An alternative form of the apparatus of this invention is shown in FIG. 4, with the vehicle therein being indicated generally at 32. As shown, the vehicle 32 includes reflector numbers 33 and 34 having concave lower surfaces for reflecting incident microwave energy of beam 14 to respective focal points indicated generally at 35 and 37. A plurality of supporting arms 40 are provided for mounting the respective engines 36 and 38 on the reflecting members 34 and 33. The diagrammatic showings of engines 36 and 38 in FIG. 4 are intended to represent jet engines of the type disclosed in my aforementioned copending application, and it is to be understood that the microwave energy necessary for operation of each engine 36 and 38 is received at the upper or intake end thereof. The focus "points" 35 and 37 are in reality areas rather than points, and the engines 36 and 38 are intentionally mounted slightly inboard of a centered position with respect to the associated area 35 or 37, so that normally not all of the energy at each area is directed into the respective engine. This condition is indicated in FIG. 4 by the several reflected dot-dash lines which pass by rather than into the mouths of engines 36 and 38. The particular proportion of energy that is thus normally wasted, as compared to that portion which is collected by the engines, is a matter of choice in design in a given instance, but it is generally desirable to utilize a major portion (e.g., 85 or 90 percent) of the available energy for normal energization of the engines. The magnitude of the portion that is normally wasted will generally be determined in accordance with the peak wind velocities occurring at the altitude at which the vehicle is to operate, as will be better understood in connection with the description of the operation of vehicle 32.

As in the case of the vehicle described in connection with the earlier figures, there will normally be other additional members employed in actual practice in order to support such operational or "pay load" equipment as radar, communications transceivers and the like. The configuration of the reflecting surface of members 33 and 34 is such as to equally divide energy of beam 14 between the engines mounted on the vehicle 32 when such vehicle is centered (both translationally and angularly) with respect to the beam 14, as shown in FIG. 4. As may be seen, the positions in which the engines 36 and 38 are mounted is such as to provide respective thrusts directed upwardly and away from the center of the vehicle 32. Thus, the thrust produced by each of the engines 36 and 38 has a major component substantially parallel to the direction of transmission of the radio-frequency energy, along with a minor component normal thereto and directed away therefrom. By means of this construction, the vehicle 32 may be maintained in flight or hovering condition and may also be controlled as to attitude in the plane of the drawing sheet. As will become apparent in connection with the description of the operation of the apparatus of FIG. 4, it will be necessary to provide three such engines to achieve attitude control in all directions.

In the operation of the vehicle of FIG. 4, when the vehicle is operating in a centered position with respect to the beam of microwave energy 14, with the central vertical axis of the vehicle in registry with the center line of the radiated beam, a propulsive thrust is provided for either propelling the vehicle upwardly or for maintaining a given altitude in opposition to gravitational forces, and the thrust components normal to the direction of the radiated beam 14 are equal in magnitude and so directed as to cancel each other.

When the vehicle 32 is moved from this desired position, as by wind forces or the like, the vehicle is re-centered on the beam by virtue of the structure described. For example, if the vehicle were to suffer translation toward the right as viewed in FIG. 4, the reflecting member 34 would lie nearer the center of the beam 14 and would therefore intercept a greater amount of radio-frequency energy that would member 33. Accordingly, engine 36 would be illuminated with more energy than falls on engine 38, and the oppositely-directed horizontal or lateral components of force exerted by the respective engines would result in a net lateral force applied to the vehicle 32 and directed toward the left in FIG. 4. This lateral correcting force will be so applied until the vehicle is once again entered on the beam. A corresponding operation obtains where the vehicle 32 is displaced laterally to the left in FIG. 4.

In addition, the structure of FIG. 4 provides automatic attitude correction to restore the vehicle to a desired position upon an unwanted angular displacement thereof with respect to the center line of the beam 14 of radiated energy. For example, if the vehicle 32 were to be angularly displaced in a clockwise direction about an axis perpendicular to the drawing sheet and passing through apex 42, the reflecting member 33 would, as a result, be moved toward a position more nearly normal to the direction of the incoming radiant energy. As a result, the angles of incidence and reflection are correspondingly increased, and the focus point 35 is moved toward the engine 38 to supply a greater level of energization thereto. A corresponding decrease in the energization of engine 36 obtains, and a net resultant force is applied to the vehicle 32 about the aforementioned axis at apex 42 to correct the attitude of the vehicle. As is evident, a similar but oppositely-directed operation occurs upon angular displacement of the vehicle 32 in a counter-clockwise direction.

The invention has been described above in considerable detail, and particularly with reference to its application to a space vehicle adapted to be maintained at a desired altitude and lateral position in spaced-apart relationship with respect to the Earth or other mother planet. However, it will be apparent to those skilled in the art that the invention is equally applicable to vehicles adapted for movement relative to such mother planet, whether involving a change in altitude, latitude or longitude, or some combination thereof, so long as a suitable beam of radiant energy is provided. The vehicle of FIG. 4 is shown and described as having a separate dished reflector for each engine. However, it is evident that a single reflecting surface of revolution may equally well be employed, along with a suitable annular collecting and distributing means, as indicated in FIGS. 1 and 2. Conversely, the separate reflectors of FIG. 4 may equally well be employed in the embodiment of FIGS. 1 and 2. Further, the embodiment of FIG. 4 is not necessarily strictly alternative to that of the preceding figures, since the two embodiments may be combined in a single vehicle to perform the combined results of each embodiment.

In addition, the invention is not limited to use of any particular form of thrust-providing engine (except as to the requirement that it be energized by received radiant energy), and the particular means for creating the propulsive thrust may be either a jet stream, a propeller or the like. In this connection, it should be noted that while the vehicle of the present invention is described as being energized solely by microwave electromagnetic energy, the vehicle may also include a conventional engine and fuel supply system for supplementing the action of the microwave engines until such fuel supply is exhausted. Also, the invention is applicable to tethered air vehicles, and where the operating altitude is low, the tethering means may serve as a transmission line for supplying energy to the vehicle without prohibitive losses. Hence the invention is not to be considered as being limited to the particular details given, nor to the specific application to which reference has been made during the description of the apparatus, except insofar as may be required by the scope of the appended claims.

What is claimed is:

1. A thrust-propelled space vehicle adapted to be maintained in a centered position with respect to a beam of radiated energy, comprising a plurality of thrust engines mounted for rotary movement about a common axis, a major portion of the thrust applied to such vehicle by each of said engines being substantially tangential to the circle of rotation thereof with a minor portion of such thrust being directed outwardly from such circle, airfoil means mounted for movement with said engines to apply a lifting force to such vehicle, means for receiving energy radiated toward such vehicle in a beam normally lying along said axis and for applying such energy to said plurality of engines to energize the latter thereby, the energy thus being applied to said engines being apportioned in accordance with the relative positions of each of said engines and the center of such beam upon a displacement of such beam away from said axis, with those engines disposed more nearly in the direction of displacement of such beam center from said axis at any given instant receiving relatively greater energization than others, whereby corrective forces are applied to such vehicle in directions substantially normal to said axis to maintain such vehicle centered on such beam.

2. A thrust-propelled space vehicle comprising a plurality of thrust engines mounted for rotation about a common axis at equal distances therefrom, a major portion of the thrust applied to such vehicle by each of said engines being substantially tangential to the circle of rotation thereof with a minor portion of such thrust being

directed outwardly from such circle, airfoil means mounted for movement with said engines to provide a lift force for sustaining air flight of such vehicle, means for receiving energy radiated toward such vehicle in a beam normally lying along said axis and for applying such energy to said plurality of engines in amounts apportioned in direct relationship with the respective distances of each of said engines from the center line of such beam at any given instant, whereby said engines are energized by such received energy to provide movement of said airfoil means and to provide corrective forces to such vehicle in directions substantially normal to said axis to maintain such vehicle centered on such beam.

3. A thrust-propelled space vehicle in accordance with claim 2, with such radiated energy being microwave electromagnetic energy, said engines including means for converting incident electromagnetic energy into propulsive thrust, and said energy receiving and applying means comprising a concave surface of revolution positioned on said axis to reflect the electromagnetic energy of such beam to said engines.

4. A thrust-propelled space vehicle adapted to be maintained in a centered position with respect to a beam of radiated energy, comprising a pair of thrust engines adapted to be energized by such radiated energy and mounted in symmetrical relationship on opposite sides of a central axis of such vehicle, said pair of engines being mounted in a substantially common plane including such central axis and at angles with respect to such axis to apply to such vehicle respective thrusts having components directed away from such axis, and means symmetrically disposed about such axis for directing energy from such beam to said engines in respective amounts apportioned in accordance with the relative distances between each of said engines and the center line of such beam, whereby said engines are differentially energized to exert corrective thrusts upon displacement of such axis from the center line of such beam.

5. A thrust-propelled space vehicle in accordance with claim 4, with such radiated energy being microwave electromagnetic energy, said engines including means for converting electromagnetic energy into propulsive thrust, and said directing means comprising a pair of concave reflecting members each reflecting a portion of the energy of such beam to a respective one of said converting means.

6. A thrust-propelled space vehicle adapted to be maintained in a centered position with respect to a beam of radiated energy, comprising a plurality of thrust engines adapted to be energized by such radiated energy and mounted in symmetrical relationship with respect to a central axis of such vehicle, the thrust produced by each of said engines being substantially confined to a respective plane including such central axis and having components both parallel with and directed away from such central axis, and means symmetrically disposed about such axis for directing energy from such beam to said engines in respective amounts apportioned in accordance with the relative distances between each of said engines and the center line of such beam, whereby said engines are differentially energized to exert corrective thrusts upon displacement of such axis from the center line of such beam.

7. A system for maintaining a thrust-propelled space vehicle in spaced-apart relationship with a mother planet at a selectable location with respect thereto, comprising a control station on such mother planet for transmitting microwave electromagnetic energy in a substantially vertically-directed beam to such vehicle, a plurality of thrust engines on such vehicle mounted for rotary movement about a substantially vertical common axis, a major portion of the thrust applied to such vehicle by each of said engines being substantially tangential to the circle of rotation thereof with a minor portion of such thrust being directed outwardly from such circle, airfoil means mounted for movement with said engines to provide a

lifting force for sustaining air flight of such vehicle, means for receiving energy transmitted toward such vehicle along said axis from said control station and for applying such energy to said plurality of engines to energize the latter thereby, the energy thus being applied to said engines being apportioned in accordance with the relative positions of each of said engines and the center of such beam upon a displacement of such beam away from said axis, with those engines disposed more nearly in the direction of displacement of such beam center from said axis at any given instant receiving relatively greater energization than others, whereby corrective forces are applied to such vehicle in directions substantially normal to said axis to maintain such vehicle centered on such beam.

8. A system for maintaining a thrust-propelled space vehicle in spaced-apart relationship with a mother planet at a selectable location with respect thereto, comprising a control station on such mother planet for transmitting microwave electromagnetic energy in a substantially vertically-directed beam toward such vehicle, a pair of thrust engines on such vehicle adapted to be energized by such radiated energy and mounted in symmetrical relationship on opposite sides of a central axis of such vehicle normally coinciding with the center line of such beam, said pair of engines being mounted in a substantially common plane including such central axis and at angles with respect to such axis to provide respective thrusts to such vehicle having components both normal to and parallel with such axis, and means symmetrically disposed about such axis for directing energy from such beam to said engines in respective amounts apportioned in accordance with the relative distances between each of said engines and the center line of such energy beam, whereby said engines are differentially energized to exert corrective thrusts upon displacement of such axis from the center line of such beam.

9. A system for maintaining a thrust-propelled space vehicle in spaced-apart relationship with a mother planet at a selectable location with respect thereto, comprising a control station on such mother planet for transmitting microwave electromagnetic energy in a substantially vertically-directed beam toward such vehicle, a plurality of thrust engines on such vehicle adapted to be energized by such transmitted energy and mounted in symmetrical relationship with respect to a central axis of such vehicle normally coinciding with the center line of such beam, the thrust produced by each of said engines being substantially confined to a respective plane including such central axis and having components both parallel with and directed away from such central axis, and means symmetrically disposed about such axis for directing energy from such beam to said engines in respective amounts apportioned in accordance with the relative distances between each of said engines and the center line of such energy beam, whereby said engines are differentially energized to exert corrective thrusts upon displacement of such axis from the center line of such beam.

10. A space vehicle, comprising body means, antenna means on said body means for intercepting incident microwave energy, means on said body means for converting said intercepted microwave energy directly into a flight-producing force applied to said body means, and means for directing microwave energy intercepted by said antenna means to said converting means.

11. A system for remotely energizing a space vehicle, comprising means at a control station on a mother planet for generating microwave energy, means at such control station to radiate such microwave energy to such space vehicle, antenna means on said vehicle for intercepting such radiated microwave energy, means on such vehicle for converting said intercepted microwave energy directly into a flight-producing force applied to such vehicle, and

means for directing microwave energy intercepted by said antenna means to said converting means.

[57] ABSTRACT

A pair of conductive spherical shells are carried by a balloon or other means into an electrical field which induces equal and opposite charges on the shells. Rotation of the shells causes the charges to alternate. The alternating sinusoidal charge is applied to an amplifier and the amplified output modulated and applied to a transmitter. The spherical shells become a telemetry antenna for transmitting the sensed electrical field information to a remote receiver.

FIG. 2.

ELECTRICAL FIELD SENSING AND TRANSMITTING APPARATUS

BACKGROUND OF THE INVENTION

The invention relates to apparatus for sensing and transmitting environmental information.

As will become apparent, the present invention, which will be referred to as an electric field meter, has been developed primarily for the purpose of measuring the growth of electrical fields in thunderclouds. For this reason, the ensuing discussion will be particularly with regard to the thundercloud application. Other uses, however, are considered to be within the present inventive scope.

There have been a number of previous efforts directed at obtaining reliable data regarding the growth and behavior of electric fields in thunderclouds. In particular, various investigators and authors have predicted that the behavior of the electric field in a cloud should be different than that at ground. For one reason, the electric field at the ground is affected by point discharge from the ground. Also, it is a fact that the air outside of clouds, especially at high altitudes, has known finite conductivity. Consequently, estimates based upon measurements made outside of a cloud, such as at ground level, are not reliable and their unreliability leaves unresolved several important questions. For example, it is important to determine how the behavior of the electric field in the cloud compares with that at the ground. Also, reliable data is needed regarding the total quantity of the charge in regions affected by lightning as well as such matters as the behavior of the electric field as a function of time inside a cloud at a point fixed relative to the cloud. Obviously, data capable of providing reliable estimates must be obtained from positions directly within the cloud. Also, it is important, particularly in obtaining the so-called 'recovery curves' (electrical field strength vs. time between lightning flashes) to assure to the maximum possible extent that the measurements are obtained from a fixed disposition relative to the cloud. To obtain such data, some previous investigators have utilized slowly moving vehicles, such as balloons or parachutes to carry the sensing instrumentation into cloud formations. For example, the following authors have described results obtained by releasing free balloons with instruments that measured the corona current through a long vertical wire:

Simpson, G. C. and Scrase, F. J., 1937, 'The distribution of electricity in thunderclouds,' *Proc. R. Soc. London A*, 161, pp. 308–352.

Simpson, G. C. and Robinson, G. D., 1940, 'The distribution of electricity in thunderclouds, II,' *Proc. R. Soc. London A*, 177, pp. 281–329

Chapman, S, 1953, 'Thundercloud electrication in relation to rain and snow particles,' *Thunderstorm Electricity*, Chicago Press, pp. 207–230

Yüan, C., Chiang, P., Jan, L., Chou, S., and Chen, T., 1965, 'A stong electrical field radiosonde and analysis of results obtained in thunderclouds,'*Ch'i-hsiang Hsueh-pao* (*Acta Meterologica Sinica*), 35, pp. 440–448.

However, although these authors were able to deduce the sign of the vertical component of the field, their estimates of the magnitude of vertical component were very rough because magnitude is related to the corona current by a non-linear function that varies with altitude. Other recorded data has been obtained by W. H. Evans, 1969, 'Electric fields and conductivity in thunderclouds,' *J. Geophys. Res.*, 74, pp. 939–948, and W. D. Rust and C. B. Moore, 1974, 'Electrical conditions near the bases of thunderclouds over New Mexico,'-*Quart. J. R. Met. Soc.*, 100, pp. 450–468. The data reported by Evans was obtained by employing parachuteborne instruments while the Rust and Moore records were obtained with the use of a captive balloon. J. A. Chalmers in a review appearing in 1967, Atmospheric Electricity, Pergamon Press, also describes a so-called "electronic flux meter" which has proven to be a useful device that in some respects is related to the present meter.

The present invention is particularly concerned with providing an improved electric field meter which is slowly moved vertically up and down through a cloud formation preferably by a balloon and parachute. In particular, it provides a combination field sensor and telemetry antenna by means of which the sensed information can be transmitted to a data-collection center for comparison with other data obtained at ground level.

The objects of the invention are concerned generally with obtaining reliable data relative to the matters which have been discussed. Also, as will become apparent, the invention seeks to obtain this data by the use of expendable apparatus or, in other words, apparatus that is so simple and inexpensive that its recovery costs normally would exceed its fabrication cost.

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention is illustrated in the accompanying drawings of which:

FIG. 1 is a somewhat schematic illustration of the present meter suspended from a balloon, and

FIG. 2 is a sectional view of the two-sphere meter showing its electronics and power supply in block form;

FIG. 3 is a view similar to FIG. 2 showing primarily a circuit diagram for achieving the present sensing and transmitting functions, and

FIG. 4 is a short segment of actual recorded data obtained by using the present system.

DETAILED DESCRIPTION OF THE INVENTION

FIG. 1 illustrates one intended use of the present apparatus in which it is suspended in a cloud formation by means of a balloon **1**. The electric field meter portion of the apparatus consists generally of a pair of hollow spherical casings or shells **2** and **3** in which are mounted the sensing and amplifying components. A support rod **4** and flexible line **6** secure the spheres to the balloon and, of particular interest, rotator blades or propellers **7** are secured to and project radially from rod **4**. The attachment fittings for coupling the rod and line should permit free rotation of the rod relative to the balloon. A bell-shaped weather protector **8** aids in keeping moisture, etcetera away from the fittings.

As will be apparent, the balloon is used to carry sensor casings **2** and **3** aloft into a cloud formation to measure its electric field strength. The function of propellers **7** is to rotate the rod and the sensor casings during ascent. The spherical casings, being conductive, receive an induced charge from the electric field and, in a particular manner to be described, this charge is transmitted to a ground station or the like.

At a predetermined or selected level, the balloon is freed by actuating a release device such as an explosive squib **9**. At the same time a parachute **11** is released to permit the meter apparatus to descend at a controlled rate. Field measurements are obtained during descent as well as ascent. The explosive squib and parachute release can be implemented in any desired manner so that it functions either responsively to a ground control or automatically at a timed interval or a predetermined altitude.

Considering the identified components in greater detail, balloon **1**, in practice, is made of 0.02 mm thick polyethylene inflated to a diameter of about 2.5 m so that the total lifting force is between 1.5–2 times the weight of the load. Thus the balloon rises even after accumulating some water and ice. Ascent velocities before entering clouds typically are 3 to 5 m/s. Neoprene meterological balloons initially were tried but they often burst before reaching the cloud base apparently as a result of hail impacts.

Contained parachute **11** is placed about 5 m above spherical casings **2** and **3**. It simply is a 1.2 m square of polyethylene with shroud lines from each corner. Descent velocity is about twice the ascent velocity. As has been indicated, no attempt is made to recover the electric field meters since they are inexpensive compared to the cost of finding and recovering them in the usually rugged terrain in which they are used.

Spherical casings **2** and **3** formed of hollow copper spheres of about 15 cm diameter and, as shown best in FIG. **3**, they are held in a manner to be described, 1.9 cm apart at the bottom end of rod **4**. The spherical shape is an important feature since it minimizes corona discharge which undesirably affects the reliability of the electric field measurements. Corona discharge from rotator blades **7** also is a factor to be considered since, during ascent, the vertical winds tend to carry such space charges past the spheres so as to contribute to the electric field component that is being measured. To minimize this undesired effect, the blades, which are made of balsa wood, are coated with a urethane finish. Other precautions also can be taken although, generally, it has been found that the blade rotation which is high at the blade tips prevents water from accumulating.

The sensing and transmitting functions of the meter are provided by spheres **2** and **3** and by the components contained in their hollow interiors. FIG. **2** shows their structure and support while FIG. **3** illustrates the system electronics. As shown in FIG. **2**, each sphere is formed of lapped hemispheres which facilitate fabrication. Sphere **3** in the implementation contains the power supply for the system which is a battery pack **12** mounted on a bracket support **13** having an outer end **14** securely bolted to the sphere and an open-flanged inner end **16** which is soft-soldered to the sphere. Sphere **2**, correspondingly contains the system electronics of block **17**. The mounting for the electronics is achieved by a bracket **13***a* formed and secured in the same manner as bracket **13**.

For reasons which will become apparent, spheres **2** and **3** should be mutually insulated as well as spaced one from the other a fixed distance. To achieve these purposes, the bottom end of rod **4** is received and pinned in a spacer block **18** formed of a dielectric material, such as teflon. Block **18**, in turn, is formed with a transverse bore receiving a nut **19** also formed of an insulating material. A bolt **21** is threaded into nut **19** to secure the two spheres in their spaced disposition. Inserts **22** and **23** are fitted flush against the inner arcuate walls of each sphere to accommodate the nut and bolt arrangement. Obviously, other arrangements can be substituted. It is, however, important to note that the present bolt **21** is provided with a central bore to receive a conductor **24** which supplies the battery power to the system electronics. It also is to be noted that another conductor **26** conducts the charge induced on sphere **3** to the system electronics for amplification and transmission. Again, the particular paths for the leads is purely a matter of choice although the fact that the charge on the casings are interconnected through the electronics is a significant feature.

The circuitry illustrated in FIG. **3** amplifies and transmits the so-called charge received through lead **26** from spherical casing **3**. Conventional electronic circuitry is used and, of course, it can be modified in any desired manner providing it achieves the desired functions. Included are a pair of amplifiers **27** and **28**, a switch arrangement **29** and a voltage controlled oscillator (VCO) **31** to modulate the switched outputs for application to an FM transmitter **32** which, in turn is electrically coupled to both spheres by conductors **33** and **34**. It also should be noted that the amplifiers are grounded to the copper surface of spherical casing **2**.

A better understanding of the operation of the meter can be obtained by considering the nature of the charges induced on the spherical casings when they are carried into an electrical field by balloon **1**. First, however, it is to be noted that the illustrated arrangement is intended primarily to measure the strength of the horizontal component of the electrical field into which it is carried. Modifications, which will be discussed, can be made if, for example, the vertical, another component, such as is involved.

As to the charges induced on spheres **2** and **3**, there are two important factor to be noted. First, due to the arrangement, these charges will be equal and opposite. Thus, because the spheres are coupled through conductor **26**, there will be a charge transfer between the spheres when they are disposed in the electrical field and the transfer will result in a positive charge on one sphere, such as sphere **2**, and a negative charge on the other. The second important factor is that, as the apparatus is borne aloft by balloon **1**, the vertical wind causes the rotator blades to rotate rod **4** so that the spheres rotate in a horizontal direction on the longitudinal axis of the rod. Although the spin rate can be a matter of choice, the present apparatus achieved a rate of 3 rps.

Rotation of the spheres alternates their relative positons to cause the charge to alternate. This alternation results in a sinusoidally varying input through line **26** to the amplifiers so that this input can be amplified, modulated and transmitted. Further, the fact that the spheres are disposed to receive horizontal field component charges coupled with the fact that the rotational axis of the spheres is normal to this horizontal component, assures output data representative of the amplitude variations of this component. The mathematical symbol used to designate the horizontal component is $\underset{\sim}{E}\perp$ and, as stated, the desired output of illustrated apparatus is $\underset{\sim}{E}\perp$. If there is a pendulum motion during the balloon or parachute flight, the vertical component will be introduced to cause a modulation of the sinusoidal signal. If this component is to be determined, the amount of modulation and the instruments maximum angle of pendulum excursion can be employed. Also, as will be discussed, other geometries can be used and other rotational drives employed to permit investigations of any desired components.

Although the electronics of FIG. 3 is straightforward, there are several factors to be especially noted. As has been described, it is important that the charge on sphere 3 be applied through the amplifiers, et cetera to the other sphere and that the output of transmitter 32 be applied to the spheres. Insulation of the spheres is used to assure that all of the charge is applied to the amplifiers.

Switching arrangement **29** is employed because it is important to provide reference voltages to permit calibration of the entire telemetry and recording components of the system. As would be expected, the transmitted data is recorded at a ground station. FIG. 4 shows a short segment of one of the records. In addition to the reference voltages, it is important in thundercloud investigations to obtain temperature data related to the event being recorded. For these purposes, the system employs a switching arrangement having four inputs. Thus, as shown, switch **29** has an input **36** which is the amplifier output for the signal of interest and inputs **37, 38** and **39.** Inputs **37** and **38** are reference voltages used for calibrations while input **39** is directly from a temperature sensor **41.** Each input has its own switch arm and the switch operation is controlled by a control logic **42** to connect and disconnect the inputs in a desired time sequence. In practice, as shown in FIG. 4, the normal output of the instrument is a sine wave **43.** A lightning event which is marked on FIG. 4 interrupts the sine wave and is recorded. Thereafter, the switches disconnect the electric field signal every 5 seconds and connect, in sequence, the reference voltage OV, the temperature sensor output and the +2V reference. It will be appreciated that other sensors and other references can be added as desired.

In practice, the value of $\underset{\sim}{E}\perp$ can be derived from V_0 by solving the electrostatic problem of two spheres in a uniform external field for the relation between $\underset{\sim}{E}\perp$ and the charges Q and —Q induced on the spheres and by analyzing the circuit for the relation between Q and V_o. These derivations have been made and the result is that:

$$\underset{\sim}{E}\perp = -(8.8\times 10 \text{ inches})(1+(\omega RC)^{-2})\,½\ A^{-1}CV_o$$

(in S1 units)

The constant 8.8×10^{11} volts meter $^{-1}$ Coul^{-1} is the ratio of electric field to induced charge for 15 cm diameter spheres held 1.9 cm apart; ω is the angular spin rate (radians/s) of the spheres about the vertical rod, R and C are the feedback resistance and capacitance of the charge amplifier 27 and A is the gain of the second amplifier. A value for V_0 and thus $\underset{\sim}{E}\perp$ is obtained for each half revolution which corresponds to a time of less than 0.2 sec. and a vertical ascent (or descent) distance relative to the surrounding air of less than 1 meter.

The operation of the apparatus should be clear from the foregoing description. In use, significant data has been recorded in which corona effect and the effect of finite conductivity of the air outside a cloud seem to be negligible. Measurements of the electric field within a cloud just before and after a lightning flash, when combined with measurements at the ground, can be used to obtain a value for the total quantity of charge in a region of the cloud just before it is partially discharged by lightning. Also, an occasion, the shape of the so-called recovery curves have been obtained for comparison with theoretical models. The recovery data is achievable in situations where there are frequent lightning flashes and the electric field appears to be a slowly varying function of position in the vicinity of the balloon.

There are a number of factors which should provide some confidence in the use of the illustrated arrangement. Thus, although the copper spheres and rotating blades both may accumulate a net electrical charge by capturing or releasing charged particles or by going into corona discharge, this accumulated charge does not move relative to the instrument and thus it does not contribute to the sinusoidal output voltage. In general, the collection and breaking away of charged particles, such as precipitation particles, produces such a small step voltage that it is too small to resolve on the records. Noise, such as might be caused by collisions, is not typically present in the records and the few examples where it has appeared probably were due to the somewhat microsphonic nature of the FM transmitter. As another factor, it has been found that the spin rate of the spheres are usually reasonably constant. Variations, of course, can affect the calibrations and they can occur due to accumulations of ice which adds mass to the instrument. However, such variations as have been noted lasted only for a short period of time and were distinquishable.

It is again to be noted that the apparatus shown in the drawings is intended only as an example of a successful arrangement and that other arrangements and applications are well within the purview of the present invention. For example, the illustrated arrangement utilizes two spheres 2 and 3. The same purpose can be served using a single sphere divided into two insulated hemispheres. The two spheres are preferred because they serve as two halves of a biconical antenna and thus have a characteristic impedance that is mostly resistive at the chosen telemetry frequency of 400 MHz. Two insulated hemispheres would have a large capacitative part which would impose difficulties. Even so, the hemisphere arrangement may be better adapted for some purposes and its use is contemplated provided, as indicated, the two halves combine to provide a spherically-shaped pair of mutually-insulated casings or shells. Further, to avoid loss of charge Q, one casing should be electrically coupled through the amplifiers circuitry to the other casing.

It also is well within present contemplation to use the arrangement for purposes other than thundercloud studies. For example, it is important to monitor the electric field charge near storage tanks or other areas containing explosives. In these situations and others, the balloon is not needed. Instead, the spheres can be mounted in a fixed position and rotated positively at any desire spin rate. Further, the disposition of the spheres is not necessarily relative to the horizontal component of the electric field. Any desired disposition can be used and rotation either can be about a horizontal axis or precessed in a controlled manner to obtain information on various components. The basic idea common to all such uses is that of employing the spherical pair to induce the essential potential difference which then is converted into a sinusoidal input for amplification and transmission. It is a significant consideration that this basic arrangement can be implemented in a relatively simple and inexpensive manner to reliably sense the electrical field and simultaneously transmit it using the same spherical arrangement used in the sensing.

It has been indicated that measurements obtained with the present instruments are utilized in conjunction with field changes obtained at the ground. The ground measurements, of course, are not a part of the present invention. However, one manner in which they may be used may be helpful in utilizing the present system. In particular, information or estimates about the net quantity of negative charge present inside thunderclouds can be obtained if both the quantity of charge neutralized and the ratio of charge neutralized to the total amount present is known. Measurements of abrupt field changes at ground accompanying lightning and of the location of the charge that was neutralized together give values of the quantity of charge neutralized. Brook et al., 1962, "Quantitative Study of Strokes and Continuing Currents in Lightning Discharges to Ground", J. Geophys. Res, 67, pp 649–659 discuss this aspect of the measurements. Measurements obtained with the present instruments provide the values necessary to obtain an estimate for the ratio. Such estimates appear to be true on an average although actual fractional variations between the compared values may be more or less than the assumed constant.

Obviously many modifications and variations of the present invention are possible in the light of the above teachings. It is therefore to be understood that within the scope of the appended claims the invention may be practiced otherwise than as specifically described.

We claim:

1. Apparatus for measuring the magnitude of the horizontal component of an electrical field in a thundercloud environment comprising:

electrical field charge collecting and transmitting means including:

a pair of substantially identical spherically shaped hollow electrically-conductive casings disposed in a closely-spaced side-by-side arrangement,

spacer block means for maintaining said side-by-side arrangement, said block means being formed of a dielectric material for structurally insulating said casings one from the other,

a charge amplifier mounted within one of said casings and provided with an input and output,

charge conduction means coupling one of said casings to said input, and

a second charge conducting means electrically coupling said amplifier output to said casings for utilizing the pair as a transmitter antenna; and

means for carrying said collecting and transmitting pair of casings upwardly into and downwardly out of said thundercloud environment, said means including:

a balloon for producing said upward movement,

rigid rod-like suspension means having its upper end carried by said balloon and its lower end fixedly secured to said spacer block means

controllable release means carried by said suspension means for releasing said balloon,

parachute means coupled to said rod-like suspension means below said release means, said means being operable upon balloon release for controlling the downward movement of said casing pair, and

propeller means fixedly secured to said suspension means below said parachute means for rotating said rod-like means and said casing pair during said upward and downward movement,

said pair of casings having a common horizontal axis normally aligned during said upward and downward movement with said horizontal component of the thundercloud field whereby the propeller-induced rotation of said casing pair produces a transmittable sinusoidal amplifier output corresponding in magnitude to said horizontal component of the electrical field, said sinusoidal output being applied to said casing pair for transmission.

2. The apparatus of claim 1 wherein said second charge-conducting means includes means for modulating said transmittable sinusoidal amplifier output.

FIG. 4

METHOD AND APPARATUS FOR CAPTURING AN ELECTRICAL POTENTIAL GENERATED BY A MOVING AIR MASS

BACKGROUND AND SUMMARY OF THE INVENTION

The instant invention relates to a method and apparatus for capturing an electrical potential generated by a moving air mass. Specifically, the instant invention describes a method and apparatus for capturing an earth-air static electrical potential which is produced by an air mass moving over a stationary airfoil.

Known apparatus and methods of producing electricity from a moving air mass utilize windmills and windmill-driven turbines. Such devices are generally mounted on fairly high towers and require complex propeller systems to effectively drive electrical turbines. The systems also tend to have a rather large affect on the air mass as it passes over the blades of a particular windmill. As with the placement of any artificial barriers in an air mass, the air mass is disturbed, and turbulence is induced into the air mass. As a particular particle of the air mass reaches the next windmill, the induced turbulence results in less driving force on the blades of the secondarily driven windmill.

The present invention does not have a propeller system, nor does it induce significant turbulence into a moving air mass. It is well documented that an object, particularly an airfoil, which is moving relative to an air mass, develops a substantial static electrical charge on its surface relative to the air mass as the result of friction between the airfoil and the air mass. This naturally occurring static charge is particularly strong when the airfoil is a conductive surface, such as a metal-covered aircraft wing. For this reason, virtually all metal-covered aircraft employ static discharge strips along the trailing edges of airfoil surfaces in order to dispel any accumulated static electrical charge.

An object of the instant invention is to collect electrical energy from movement of an air mass over an airfoil.

Another object of the instant invention is to collect electrical energy with a non-complex collecting element.

A further object of the instant invention is to collect electrical energy from movement of an air mass over an airfoil with a substantially non-turbulence producing system.

A further object of the instant invention is to describe a method of collecting electrical energy from the frictional effects of an air mass moving over a conductive airfoil.

The electrical system of the instant invention includes a conductive airfoil, which is rotatably mounted on an insulated bearing, the airfoil being free to align itself with a moving air mass. A second component of the system is a ground rod which extends down to a water table level. Electrical leads are connected to a conductive portion of the airfoil and to the ground rod, and are then connected to a storage battery.

The method of collecting electrical energy from the system involves connecting the negative side of the storage battery to the airfoil and connecting the positive side of the battery to the ground rod. As an air mass moves over the surface of the airfoil, an electrical charge is produced and transmitted to the storage battery. Electrical energy may be drawn from the storage battery as needed.

These and other objects and advantages of the instant invention will become more fully apparent as the detailed description of the invention which now follows is read in conjunction with the drawings.

DESCRIPTION OF THE DRAWINGS

FIG. **1** is a front elevation of an earth-air electrical current friction generator constructed according to the instant invention, with portions broken away to show interior detail.

FIG. **2** is a top plan view of the generator of FIG. **1**.

FIG. **3** is a schematic plan view of a generator field constructed according to the instant invention.

FIG. **4** is a view of the generator field of FIG. **3**, taken generally along line **4**—**4** in that figure.

FIG. **5** is a graph depicting the relationship between current production and wind speed associated with the generator of FIG. **1**.

DETAILED DESCRIPTION OF A PREFERRED EMBODIMENT

Turning now to the drawings, and in particular FIG. **1**, an earth-air electrical current friction generator made according to my invention is depicted generally at **10**. The generator includes a metal airfoil, or conductive airfoil means, shown generally at **12**, which is supported by a rotatable airfoil mount **14** and an electrically conductive electrode **16**. A battery **18** provides storage capability for the collecting apparatus.

Airfoil **12** is vertically mounted above ground level. The airfoil is a zero-lift structure in the preferred embodiment, since both active surfaces are symmetrical. Airfoil **12** is formed of a conductive metal skin **20**, formed of lightweight aluminum sheeting in the preferred embodiment, over a frame **22** which is shown behind the cut-away portion of skin **20**. Frame **22** may be formed of any suitable material, such as wood, plastic or metal. In the preferred embodiment, frame **22** is a substantially square structure.

A wind vane **24** is mounted on the top and at one side of airfoil **12**. Wind vane **24** is also referred to as an air mass alignment means, and provides that airfoil **12** will be windfollowing.

An airfoil support bracket **26** is attached to the base of airfoil **12**. One end of a support post **28** is received within bracket **26**. The other end of post **28** terminates in a non-conductive airfoil bearing race **30** and is received within mount **14**. Bracket **26** and post **28** are electrically conductive and are electrically connected to skin **20**.

Rotatable airfoil mount **14**, or rotatable airfoil mounting means, electrically insulates airfoil **12** from electrode **16**, and is referred to herein as isolation means or isolator means.

Airfoil mount **14** is, itself, supported by an above-ground portion **16*a*** of electrode **16**. Portion **16*a*** terminates in a non-conductive electrode bearing race **32**. A bearing **34** is interposed race **30** and race **32**. The respective airfoil and electrode components are retained together by means of a fastener **36**, which is a nut and bolt combination in the preferred embodiment. Fastener **36** aligns with an airfoil axis of rotation **38**.

Mount **14** is enclosed by a cylindrical enclosure **40** which is secured to portion **16*a*** and which allows post **28** to rotate within a weathertight seal **42**. Enclosure **40** and seal **42** are, of course, electrically non-conductive.

Electrode **16** extends through whatever ground layers exist beneath the surface, which are depicted generally at **44**, and then extends into a permanent water table layer **46**. Extending electrode **16** into a water table provides an electrical surface which is as large as the water table. Although the generator would function if electrode **16** did not extend into a water table, the operation of the generator is greatly enhanced by extending electrode **16** to a water table, for reasons which will be explained later herein.

An electrical commutator **48**, and a grounding screw **50**, make electrical contact with post **28** and portion **16***a*, respectively. Commutator **48** is insulated from and fastened to enclosure **40** by bracket **48***a*. Commutator **48** is connected to a lead line **52** which is attached to battery negative terminal **18***a*, and screw **50** is attached to lead line **54** which is attached to battery positive terminal **18***b*. The commutator, screw and lead line comprise what is referred to herein as means for connecting, or connecting means.

Battery **18**, although represented in FIG. **1** as a solitary unit, may obviously include a plurality of units, connected in series or parallel, depending on the output of generator **10**. A pair of leads **56**, **58**, are shown coming off of battery **18**, and would presumably be attached to an electrical distribution system, possibly through an A.C. inverter. The battery and leads **56**, **58** compise an electrical system.

As an air mass moves over skin **20** of airfoil **12**, there occurs an exchange of ions between the air mass and the surface of the airfoil. This exchange takes place as an air mass moves over any stationary object. In most instances, however, the object is sitting on the surface of the earth, in electrical communication therewith, and a charge does not accumulate on the surface of the object. Since the airfoil of the instant invention is insulated from the earth, a static charge builds up on the surface of the airfoil as an air mass flows over the airfoil.

As the air mass moves over airfoil **12**, a collection of negatively charged ions builds up on the airfoil surface. Were there no electrical connection whatsoever between airfoil **12** and ground surface **44**, and were it not for the fact that eventually a charge built up on airfoil **12** would dissipate into the air mass, a charge would eventually build up on airfoil **12** of sufficient strength to arc, such as thc arc produced between a thunderstorm and the ground in the case of lightning, resulting in the complete discharge of the negative ions accumulated on airfoil **12**.

The electrical charge which accumulates on airfoil **12** is drawn off of the airfoil by means of commutator **48**, which is attached to battery **18**. A corresponding positive charge is drawn off of electrode **16** by means of screw **50**.

The surface area of airfoil **12** is defined by what is referred to herein as a cross-section square inch. This unit is depicted at **60** in FIGS. **1** and **2**. The unit is measured on both sides of the airfoil. The distance between the sides of the airfoil is not a factor. So long as the surface area in electrical contact with electrode **16** equals or exceeds the surface area of airfoil **12**, the generator will produce a current flow of 1-milliamp-per-square-inch of airfoil surface cross section with a wind speed of 7-miles-per-hour.

Because the airfoil collects negative ions, it is sometimes referred to as a negative collector element. Likewise, since electrode **16** acts as a source of a positive charge, it is sometimes referred to as a positive collector element, or conductive earth means.

Turning now to FIGS. **3** and **4**, a friction generator farm **62** is depicted schematically in FIG. **3**, and in a pictorial cross section side view in FIG. **4**. A generator farm, according to the instant invention, would include at least one conductive electrode **64**, placed in the ground down to the level of a permanent water table, which would act as a positive collector element. A plurality of airfoils is depicted by even numbers **66** through **80**. Electrode **64** is connected to a positive side of an electrical system by a conductive line **82**. Airfoils **66** through **80** are connected to a common negative lead **84** which connects to the negative side of an electrical system.

Turning now to FIG. **4**, a side sectional view of generator farm **62** is shown. Electrode **64** is placed in ground, represented by **44** as are the support posts for the airfoils. It should be noted that in this type of arrangement, a single commutator would be required within airfoil mounts **70***a*, **68***a*, **66***a*, **80***a* and **78***a*. An airfoil structure support post, represented at **70***b*, **68***b*, **66***b*, **80***b* and **78***b* may be formed from an electrically insulative material when a single electrode, like that shown at **64**, is utilized, thereby further simplifying the internal portions of the airfoil mount.

In addition to earth-air friction generators, a pair of lightning rod devices **90**, **92**, are shown in FIG. **4**. Rods **90** and **92** also are extended subsurface to provide protection from lightning strikes in the vicinity of generator farm **62**. A generator farm of the type described would be particularly susceptible to damaging lightning strikes were such lightning rods not provided.

Returning for a moment to FIG. **3**, a wind arrow **94** is depicted to show a prevailing wind and direction of air mass movement. It will be noted that airfoils **66** through **80** have aligned themselves with the wind indicated by arrow **94**. It should also be noted that with a generator farm in the layout proposed in FIG. **3**, there would be very little disturbance of wind flow by the airfoils of the generator farm. This is in extreme contrast to the turbulence and generally delaminating effect of conventional windmill generating farms.

It should also be obvious to those skilled in the art that the construction of the generator of the instant invention is many orders of magnitude less complex than the construction required for a conventional windmill-type turbine generator.

Turning now to FIG. **5**, a graph of current output per crosssection square inch mA/in^2 versus wind speed V (mph) is depicted. The above-described generator will produce 1-milliamp of electrical current per cross-section square inch with a 7-mile-per-hour wind. Generator output increases linearly, such that the generator will produce 10-milliamps per cross-section square inch in a 70-mile-per-hour wind. It should also be noted that very few known windmill turbine generators function in a 7- or 70-mile-per-hour wind. The generator of the instant application does not have such a limitation. The generator will produce current in any amount of wind, light or strong. As long as the structure is sufficiently durable to withstand a high wind, the system will continue functioning and producing an electrical current. Most systems are restricted to operations over a set wind speed range, generally in the 10- to 45-mile-per-hour range. Systems which produce electricity in extremely light wind conditions are very costly.

Assume for a moment, that an individual airfoil is constructed with sides which are 10-feet in length, thereby producing a cross section dimension on the order of 100-square feet, and further assume that ten airfoils are arranged similar to generator farm **62**, thereby resulting in a total cross section area of 1,000-square feet. The generator farm so described, when connected to a 12-volt D.C. system, and when excited by a wind of 7-miles-per-hour, will produce 1,728-watts of electrical energy.

Thus, a new method of capturing a usable electric current, and an apparatus for practicing the method described have been disclosed. While a preferred embodiment of the invention has been described, it is appreciated that variations and modifications may be made without departing from the spirit of the invention.

It is claimed and desired to secure by Letters Patent:

1. An earth-air electrical current friction generator which comprises

conductive earth means extending subsurface into a water table,

conductive airfoil means operatively associated with said earth means extending above surface into an air mass responsive to airflow to produce an electrical potential relative to said earth means,

isolation means electrically insulating said airfoil means from said earth means, said isolation means including a rotatable airfoil mounting means which allows said airfoil means to rotate in such an air

mass and which supports said airfoil means above surface,

an electrical system, and

means for connecting said airfoil means and said earth means to said electrical system for conduction thereto of an electrical current.

2. An electrical charge collector which comprises

a positive collector element extending to a water table,

a negative collector element operatively associated with said positive collector element, said negative collector element being wind-following and including wind alignment means for aligning said negative collector element with a prevailing wind,

isolator means for insulating said negative collector element electrically from said positive collector element, said isolator means including a rotatable mounting which rotatably supports said negative collector element, and

connecting means for providing an electrical connection from each of said elements to an electrical system.

3. The collector of claim **2**, wherein said positive collector element includes at least one conductive electrode.

4. The collector of claim **2**, wherein said negative collector element includes at least one conductive airfoil.

[57] ABSTRACT

Apparatus for and methods of converting radio frequency energy into direct current for generating electric power includes a dipolar antenna for receiving radio frequency energy and a circuit connected thereto for converting the radio frequency energy to direct current. The circuit has a positive output line connected to one pole of the antenna and a negative output line connected to the other pole of the antenna. A positive transmitting diode is in the positive output line and a negative transmitting diode is in the negative output line. First and second bus lines and a pair of tuned circuits of opposite polarity couple the positive output line and negative line to the bus line with one of the bus lines being connected to ground. Each tuned circuit includes a first bridging line connecting the positive output line to the first and second ground lines and a second bridging line connecting the negative output line to the first and second ground lines. Each bridging line has a diode therein oriented at a polarity which is reverse with respect to the input diode. The bridging lines of each tuned circuit are connected to one another by an inductance and have capacitors disposed between the diode and the bus lines. A direct current device is connected to the positive line of the circuit.

APPARATUS FOR CONVERTING RADIO FREQUENCY ENERGY TO DIRECT CURRENT

BACKGROUND OF THE INVENTION

1. Field of the Invention

The instant invention relates to methods of an apparatus for converting radio frequency energy to direct current; more particularly, the instant invention relates to methods and apparatus for converting radio frequency energy to direct current wherein the direct current is of sufficient magnitude to power devices such as battery charges and electric motors without the use of amplification.

2. Technical Considerations in Prior Art

There has long been interest in technology directed to transmitting electrical energy over a distance without utilizing conductors, such as wire conductors. Development of such a technology has enormous potential. This was first recognized by Nikola Tesla who in 1899 constructed a 200 foot Tesla coil rated at 300 kilowatts and 150 kilocycles. Tesla hoped to set up standing waves of electrical energy around the whole surface of the earth, so that receiving antennas set at optimum points could tap the power when needed. Tesla was able to light hundreds of lamps at a distance of about 40 kilometers with his device without utilizing electrical conductors. The scheme has generally remained a scientific curiosity but has provided the initial groundwork for current developments wherein attempts are being made to transmit power by microwaves. However, power transmitted by microwaves is envisioned in the form of a beam of very high intensity which is focused from a microwave generator to a receiving antenna. This technology is envisioned as being used for many types of purposes such as transmitting microwave energy collected from gigantic solar power satellites and "star wars"-type weapons systems. However, the focused microwave beam is not suitable for many applications in that the beam must be directed toward a receiving antenna and cannot be transmitted through most objects, including living objects, without destroying the objects.

The instant invention relies on converting energy from standing waves which are emitted from radio frequency antennas in the RF range rather than the microwave range. Of particular interest are very low frequencies which are not used in communications and are available for transmitting power. Also of interest with respect to the instant invention are the low frequency waves emitted by the earth due to pulsation thereof caused by its magnetic field. These low frequency standing "earth" waves can be picked up by receivers tuned thereto.

SUMMARY OF THE INVENTION

It is an object of the invention to provide new and improved methods of an apparatus for converting radio frequency currents to direct current for practical uses other than communications, wherein the direct current energy converted from the radio frequency input energy does not require amplification.

Upon further study of the specification and appended claims, further objects and advantages of this invention will become apparent to those skilled in the art.

The instant invention contemplates an RF antenna for receiving radio waves. The RF antenna connected to a circuit configured in accordance with the principles of the instant invention to convert the RF signals to direct current. The radio frequency signals received by the antenna are transmitted to first and second leads, with one lead being rectified to transmit positive voltage and the other lead being rectified to transmit negative voltage. The positive voltage lead being connected directly to a positive output line and the negative voltage lead being connected directly to a negative output line. The positive output line is connected to a pair of bus lines through a first pair of capacitors, while the negative output line is connected to the pair of bus lines by a second pair of capacitors. Disposed between the first bus line and the positive output line is a reverse diode of negative polarity, while disposed between the negative output line and first bus line is a reverse diode of positive polarity. The positive and negative output lines are connected to one another through an inductance which is in parallel with the capacitors of the first and second pair connected between the second bus line and the positive and negative output lines.

In accordance with one embodiment of the invention the afore-described circuit is duplicated for each positive and negative output line. In accordance with another embodiment of the invention, the afore-described circuitry is coupled to additional circuits identically configured in order to increase the direct current output of the arrangement.

In accordance with a further configuration of the invention, the antenna utilized is a dipolar antenna of aluminum wire arranged in a "butterfly" configuration.

The instant invention further contemplates the method of utilizing the afore-described elements so as to generate direct current having sufficient power to perform tasks such as charging batteries, lighting lamps and powering direct current electric motors without the use of amplifiers.

BRIEF DESCRIPTION OF THE DRAWING

Various other objects, features and attendant advantages of the present invention will be more fully appreciated as the same becomes better understood when considered in connection with the accompanying drawing, in which like reference characters designate the same or similar parts throughout the several views, and wherein:

There is shown a diagram of a circuit in accordance with the instant invention in combination with a driven device and a dipolar antenna which receives radio frequency waves which are converted to DC current for powering the driven device.

DESCRIPTION OF THE PREFERRED EMBODIMENT

Referring now to the drawing, there is shown a dipolar antenna, designated generally by the numeral **10**, which receives radio frequency waves from an RF transmitter **11**. The radio frequency waves are transmitted to a radio frequency to direct current converting circuit, designated generally by the numeral **12**, through a coaxial cable **13** and DC current from the circuit **12** is used to power an output device, designated generally by the numeral **15**, which may for example by a battery charger DC motor or lighting device. The circuit **12** has no other power inputs other than the radio frequency energy transmitted thereto by the antenna **10** and therefore includes no amplifiers for amplifying the RF energy.

The source of radio frequencies convertible to direct current by the circuit shown may include sources of high frequency, low frequency (LF), very low frequency (VLF) and extremely low frequency (ELF) radio waves as well as seismic vibration of the earth's magnetic fields.

Preferably, the dipolar antenna **10** is formed of two triangular loops of aluminum wire **16** and **17**, one of which is connected to the annular conductor **18** of the coaxial cable **13** and the other of which is connected to the center conductor **19** of the coaxial cable. The size of the bipolar antenna **10** is dependent on the particular application to which it is put. In accordance with one embodiment of the invention, the antenna **10** is approximately 12 inches in width and 18 inches in length. Such an antenna is used to receive five watt energy, such as that generated by a walkie-talkie or citizen-band radio.

The annular conductor **18** of the coaxial cable **13** is connected to a positive lead **21** of the circuit **12**, while the center conductor **19** of the coaxial cable is connected to a negative lead **22** of the circuit. A positive transmitting diode D1 is disposed between the lead **21** and the remainder of the circuit **12** while a negative transmitting diode D2 is disposed between the lead **21** to a positive output line **25** while the negative diode D2 is connected to a negative output line **26**. Accordingly, the positive voltages with respect to ground are produced on output line **25** and negative voltages with respect to ground are produced on output line **26**.

In order to provide a DC output of sufficient power, a plurality of inductance-capacitance, RF, tuned circuits **30**, each forming a positive cell, or a negative cell, are utilized for connecting the positive output line **25** and negative output line **26** to first and second bus lines **31** and **32**, respectively. Bus line **32** is connected to ground while bus line **32** can be connected to circuits similar to circuit **12**. The positive output line **25** is connected by a first bridging line **33** to the first and second bus lines **31** and **32** while the negative output line **26** is connected by a second bridging line **34** to the first and second bus lines. The bridging line **33** has capacitors C1 and C2 disposed between the positive output line **25** and the first and second bus lines **31** and **32**, while the bridging line **34** also has capacitors C1 and C2 dispensed between the negative output line **26** and the first and second bus lines **31** and **32**. Connected between the bridging lines **33** and **34**, is an inductor **35** which serves as an RF choke, while disposed between the positive output line **25** and the capacitor C1 there is a negative polarity diode D4 referred to herein as a bridging diode and disposed between the negative output line **26** and capacitor C1 in line **34** there is a positive polarity diode D3 referred to herein as a bringing diode. As is seen of the drawing, the RF tuned circuit cell **30** is repeated a plurality of times. In the specific example shown, the circuit **12** has separate cells **30**, **37**, **38** and **39**. The cells **30** and **38** are of opposite polarity and balance one another while the cells **37** and **39** of opposite polarity and also balance one another. In order for the system to function, a pair of opposite polarized cells must be utilized. The particular number of cells **30** and the value of the components thereof are determined by the configuration of the dipolar antenna **10** and the power and frequency of the RF transmitter **11**.

The radio frequency to direct current conversion circuit **12** may itself be connected to a duplicate circuit via pins **41** so as to provide additional direct current output on lines similar to positive output line **25** and negative output line **26** the output lines may be connected together in order to boost the total output of the system.

An operative embodiment of the invention utilizes the following elements:

Diodes D1, D2, D3 and D4—Germanium Diodes, Archer **1** N34A,Catalog #1123.
Inductor 35-47 Milli henry R. F. Choke
Capacitors C1 and C2-0.47 Pico Farads at 200 volts
Coaxial Cable 13—50 ohms
Dipolar Antenna 10—aluminum wire triangular loops approximately 12 inches by 18 inches.

From the foregoing description, one skilled in the art can easily ascertain the essential characteristics of this invention, and without departing from the spirit and scope thereof, can make various changes and modifications of the invention to adapt it to various usages and conditions.

What is claimed is:

1. Apparatus for converting radio frequency energy into direct current for generating electric power, the apparatus comprising:

a dipolar input for receiving radio frequency energy;

a positive output line connected to one pole of the dipolar input and a negative output line connected to the other pole of the dipolar input;

a positive transmitting input diode means in the positive output line and a negative transmitting input diode means in the negative output line;

first and second bus lines and a pair of tuned circuits of opposite polarity coupling the positive output line and negative output line to the bus lines, one of the bus lines being connected to ground;

each tuned circuit including a first bridging line connecting the positive output line to the first and second bus lines and a second bridging line connecting the negative output line to the first and second bus lines, each bridging line having a bridging diode means therein oriented at a polarity which is reverse with respect to the transmitting input diode means of the respective output line; the bridging lines of each tuned circuit being connected to one another by an inductance and having capacitors disposed between the bridging diode means thereon and the bus lines, and

a direct current device connected to the bridging lines of the tuned circuit.

2. The apparatus of claim **1**, wherein there are a plurality of similarly configured tuned circuits connected between the output lines and the bus lines.

3. The apparatus of claim **2**, wherein there are a plurality of radio frequency-to-direct current conversion circuits connected to one another to provide a direct current power array tuned to a specific radio frequency such as a high frequency source, low frequency source, very low frequency source, extremely low frequency source, or source created by seismic vibrations of the earth's magnetic field.

4. The apparatus of claim **3** wherein the dipolar input is a dipolar antenna.

5. The apparatus of claim **1**, wherein the device connected to the output lines is a direct current motor.

6. The apparatus of claim **1**, wherein the device connected to the output line is an illuminating device.

7. The apparatus of claim **1**, wherein the device connected to the output lines is a battery charger.

8. The apparatus of claim **1**, wherein the device connected to the output lines is a DC-to-AC inverter.

9. The apparatus of claim **1**, wherein there are a plurality of radio frequency to direct current converter circuits connected to one another to form an array of circuits tuned to a particular radio frequency.

10. The apparatus of claim **1** wherein the dipolar input is a dipolar antenna.

11. The apparatus of claim **10**, wherein the dipolar antenna utilizes aluminum wire arranged in pair of triangular loops.

[57] **ABSTRACT**

A method and device for generating an electric current and power from the earth's electric field. The electric current is generated by providing a thermoemissive material at some distance above the earth's surface, connecting the thermoemissive material to the earth's surface with a conductor (e.g., wire) such that a conductive path is established between the thermoemissive material and the earth's surface through the conductor, and heating the thermoemissive material to cause it to emit electrons into the surrounding air, thereby drawing replacement electrons from the earth's surface through the conductor to the thermoemissive material. One way to produce power in the above setting is by installing a D.C. electric motor or other electrical device along the said conductive pathway.

METHOD AND DEVICE FOR GENERATING ELECTRICITY

FIELD OF THE INVENTION

The present application relates generally to a method and device for producing electricity, and more particularly to a method and device for generating an electric current and power using the earth's electric field.

BACKGROUND OF THE INVENTION

It is known that the earth is under a relatively strong electric field, observed between the surface of the earth and its surrounding air. This field arises from the fact that the air has a net excess of positive ions (i.e. is positively charged), whereas the earth's surface has a net excess of electrons (i e. is negatively charged). By the laws of electrostatics, each of these net charges tends to be uniformly distributed everywhere in the air and on the ground surface, respectively.

In spite of these quasi-uniform distributions, the induced electric field is still relatively strong, approximately 130 V/m measured on the surface of the sea. Although this voltage looks attractive for generating electricity, the problem is that it is accompanied by a relatively small electric-current density: the air's net positive-ion density n_i is very low, so that the resulting net ion-current density $J=n_i \times v_i$ toward the earth's surface is almost zero. Thus, for example, if one connects one bare end of an insulated wire with the earth's surface (negatively charged) and the other bare end with a horizontal metallic surface in the (positively charged) air, one would measure very little current flowing through the wire, proportional to the exposed area of the metallic surface. Accordingly, to date there has been no successful way developed to use the earth's electric field for significant electricity production.

A need therefore exists for a method of generating electricity by taking advantage of the earth's electric field. The present invention addresses that need.

SUMMARY OF THE INVENTION

Briefly describing one aspect of the present invention, there is provided a method for generating an electric current and power using the earth's electric field. The electric current is generated by providing a thermoemissive material at a distance above the earth's surface, connecting the thermoemissive material to the earth's surface with a conductor so that a conductive path is established between the thermoemissive material and the earth's surface through the conductor, and heating the thermoemissive material to cause it to emit electrons into the surrounding air, thereby drawing replacement electrons from the earth's surface through the conductor to the thermoemissive material. Electric power is produced by installing a direct-current electric motor or other electrical device somewhere along the conductive path. One objective of the present invention is to provide a method for generating an electric current and power. Further objectives and advantages of the present invention will be made obvious by the following description of the preferred embodiments.

BRIEF DESCRIPTION OF THE DRAWING

FIG. **1** shows the apparatus of the present invention, according to one preferred embodiment, where:

W—wire or other electrical conductor;
D—conductive disc, in contact with one end of W_1;

M—direct-current (D.C.) electric motor;
G—alternating-current (A.C.) generator, powered by M;
P—thermoemissive material, could be a plaque or plate;
E—electrode, in contact along one whole side of P;
R—roostat, or other suitable voltage-regulating device;
A—conductor, connecting a pole of G with an end of R; and
I_1—insulating material, which takes on the weight of W_2, P, E_1, E_2 and part of W_3 and W_4. That weight is passed on to W_1, and from there onto D. Other weight-supporting schemes are possible.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

For the purpose of promoting an understanding of the principles of the invention, reference will now be made to preferred embodiments and specific language will be used to describe the same. It will nevertheless be understood that no limitation of the scope of the invention is thereby intended, such alterations and further modifications in the illustrated device, and such further applications of the principles of the invention as illustrated therein being contemplated as would normally occur to one skilled in the art to which the invention relates.

As previously indicated, the present invention relates generally to a method for generating an electric current and power by taking advantage of the earth's electric field. The method generally comprises providing a thermoemissive material at some distance above the earth's surface, connecting the thermoemissive material to the earth's surface with a conductor (e.g., wire) and heating the thermoemissive material to cause it to emit electrons into the surrounding air, thereby drawing replacement electrons from the earth's surface through the conductor to the thermoemissive material. A sample apparatus for practicing the present invention is shown in FIG. **1**.

One of the most critical elements of the inventive apparatus is the thermoemissive material. For the purposes of this invention, a thermoemissive material is any material that emits electrons when appropriately heated or irradiated. In some preferred embodiments the thermoemissive material ("thermat") is a solid sheet or layer, while in other embodiments the thermat is in a molten or fluid state.

Preferred thermats include pure metals (such as Mo), and their alloys, and unsintered or sintered ceramics (especially metallic ceramics, "cermets", such as Mo-sintered BaO/SrO). Ni/BaS and Pt/BaS sintered cermets are preferably used in some embodiments.

As shown in FIG. **1**, the thermat may be plated onto a plaque which is suspended (e.g., horizontally) at some distance above the earth's surface. Preferably, the thermat is suspended at a distance of at least a two meters above the earth's surface. As is known to the art, the magnitude of the potential difference increases with increasing height above the earth's surface (except for random effects of significantly reduced local net-ion density in the surrounding air), so the higher the thermat is placed above the earth's surface (up to a naturally-prescribed limit), the greater the total voltage available for producing electricity.

The thermat is generally connected by a conductor to the earth's surface. In one preferred embodiment the conductor is copper wire, although other materials, especially tungsten, may be used. The conductor provides a conductive path for electrons to pass from the earth's surface, through a D.C. electric motor, to the thermat, where they are emitted into the surrounding air. The D.C. electric motor powers a generator, which in turn produces the A.C. electricity. In one embodiment the conductor is made of many thin wires, as further described below.

With the present invention the thermat must first be heated to put it in a state of emitting electrons. Once electrons are being emitted from the thermat, they will be driven away (skywards) by the earth's electric field and simultaneously be scattered by collisions with air molecules. That emission will cause replacement electrons to be drawn through the conductive path to the thermat, forming the electric current that powers the D.C. electric motor. When the thermat has been heated to the point that the desired level of constant flow of electrons is fully established, a steady state operation of the device has been achieved.

Because it is necessary to keep the thermat hot, the conductors attached to it will also heat-up and may thus need adequate cooling to keep their temperature down. To this end, the conductors W can be left partially or totally uninsulated, with the many and thin individual wires of each pulled apart from one another and their bare surface roughened, for maximum ventilation effect. Also, many thin cooling ffins can be vertically welded all over the free upper surface of the disc, made of the same material as the disc and with their outer surface roughened. Lastly, the free upper surface of the disc can be carefully sprayed periodically with regular tap water, to induce on it refrigeration via evaporation of liquid H_2O. Additional cooling measures, such as artificial refrigeration of the conductors W and/or the disc, etc., can also be adopted if necessary.

The basic procedure for practicing the present invention, according to one preferred embodiment, is described below. First, a small piece of land with a generally flat area is selected. The elevation of the land is preferably close to sea level. All bushes and/or trees are removed from inside a 10-meter radius of the geometric center of the flat area of the land. All other trees or bushes in the flat area of the land are trimmed, so that none exceeds in height the elevation of the thermat to be installed.

Moist soft soil is provided over the 10-meter radius of the flat-ground area described above, to a thickness of about 70 centimeters. A copper disc D, approximately 20 meters in diameter and 10 cm in thickness, is laid horizontally on the soft soil. This disc is the base of the device. For best operation of the device, the disc D is connected with one or more thick (uninsulated) copper wires to seawater (if the sea is nearby). In other situations, lakewater, riverwater or even the main pipe of potable tap-water can be used to establish electrical connection with the disc.

One end of a copper wire W_1 is welded to the center of the (upper) surface of the copper disc D. Wire W_1 is positioned perpendicular with respect to the copper disc D, and its other end is steadfasted (fixed) to the bottom of an insulating material I_1.

A second copper wire W_2 has one end steadfasted (fixed) to the top of I_1 and extends upward from I_1. The upper end of W_1 and the lower end of W_2 are respectively connected (via externally insulated conductors) to the two poles of a D.C. electric motor M. The weight of the motor is preferably supported with a pedestal base fastened on the copper disc D and made of a strong, hydrophobic, insulating plastic; the motor's weight is not carried at all then by W_1.

An A.C. generator G is mounted on a similar pedestal base; that base is also fastened on the copper disc D and its height and position are chosen such that the rotating axis of the generator is along the same straight line as that of the motor M. The motor's rotor is then mechanically joined with the generator's rotor. The proper thermal-expansion/contraction margin for the two rotors is allowed in the design of their mechanical joint.

The generator and the motor must not be in contact with any materials except for the externally insulated conductors whose ends are electrically attached to their poles, the insulating pedestals they sit on, the mechanical joint between their rotors, and the surrounding air.

To protect from the rain, the whole system (except for the thermat)may be placed under a waterproof tent, preferably made of thin plastic. The bottom part of the walls of the tent is cut-off and removed (e.g. the bottom 1 meter), to secure adequate ventilation and cooling of the device.

The composite thermoemissive plaque simply consists of a tungsten sheet whose one free surface is plated with a very thin (e.g. 0.1 micron) layer of the thermoemissive material of choice (e.g. 50% BaO+50% SrO). Such plaques have already been made and tested for their thermoemissivity routinely, as mentioned in the pertinent literature. An example of such a fabrication is given in the next two paragraphs. First, a very thin (e.g. 0.1 micron) ceramic sheet is supported horizontally via four thin rods, that are made of insulating material and are placed at the four corners of the mid-rectangle of one side (referred to henceforth as "the bottom") of the sheet. The melting point of the insulating material of the rods must be higher than the melting point of tungsten. For example, cement or a ceramic material may be used.

A tungsten sheet of the same perimeter as the ceramic sheet is then placed on the top-surface of the latter, so that their four edges align exactly. The bottom of the ceramic sheet is then heated until its top (where the tungsten sheet rests) reaches the melting point of tungsten; this temperature is maintained until the tungsten sheet thermally bonds with the top of the ceramic sheet by infusion of liquid tungsten into the microscopic pits, scratches and cracks of the top-surface of the ceramic sheet.

When the above process is over, the thermoemissive plaque P has been formed and is allowed to cool down to room temperature, via natural convection.

The upper (free) end of the wire W_2 is made of tungsten and is welded to the center of the tungsten surface of the plaque, so that the W_1-I_1-W_2 structure supports the plaque and, via the electric motor M, also provides the link for the plaque's electric contact with the ground.

In one embodiment, an electrode is attached along each of two opposite sides of the tungsten's periphery on the thermoemissive plaque P. One such electrode, E_2, is connected by the conductor W_3 to one pole of the generator G, and the other such electrode, E_1, is connected via the conductor W_4 to a very strong electric heat resistance, which is part of a very large roostat R, whose steady arm (conductor) A is in turn connected to the other pole of the generator. The purpose of this auxiliary circuit between the generator's two poles, is to electrically heat the thermat, to cause the emission of electrons from the thermat into the surrounding air. Of course, other means for heating the thermat may be used, such as very hot gas(es), electromagnetic or other radiation, etc. When electrical-resistance heat is used as shown in the preferred embodiment, all electric connections are preferably done with insulated copper wires, and, in the vicinity of the plaque, tungsten wires.

As one example of how the device may be started, an external electric power source that can supply 5000V and 2000 A (10 MW) D.C. to the poles of the electric motor may be used. Such a power source could be one or more diesel engines coupled with the proper generator(s); or a transformer with A.C. input from the city network and 5000V/2000 A D.C. output. A roostat can regulate the percentage of the above external electric power given to the motor.

When the above 100 MW electricity is supplied to the motor, the generators roostat R FIG. **1** is set so that all the electric output of the generator G goes through the whole regulating resistance of FIG. **1**. Gradually, more of the generator's power is slowly provided for heating the thermat, causing the device to start delivering its own electricity on the motor (at 5000V D.C.). Simultaneously, we start lowering the externally-supplied D.C. current to the motor, so that the total D.C. current supplied to the motor is at all times kept constant at 2000 A. This procedure is continued until all 2000 A D.C. delivered to the motor eventually come from electrons flowing from the copper disc D to the thermoemissive plaque P. Steady-state operation of the device has then been achieved.

Other start-up procedures for heating-up the thermat and bringing the device to a desired steady state of operation exist. For example, the thermat may be bombarded with electromagnetic radiation and/or hot gas(es), etc. In one preferred embodiment, hot gases are used to heat the thermat and bring the device to its steady state of operation.

It is to be appreciated that some secondary components of the device have not been illustrated in the Figure, because they would make the schematic too dense in detail and hard to understand. For example, the external power supply used to start-up the operation of the device has not been shown, although persons of skill in the art can easily appreciate its role.

While the invention has been illustrated and described in detail in the drawing and the foregoing description, the same is to be considered as illustrative and not restrictive in character, it being understood that only the preferred embodiment has been shown and described and that all changes and modifications that come within the spirit of the invention are desired to be protected.

What is claimed is:

1. A method for generating an electric current and power, comprising:

(a) providing a thermoemissive material positioned above the earth's surface;

(b) connecting the thermoemissive material to the earth's surface with a conductor, so that a conductive path is established between the thermoemissive material and the earth's surface through the conductor;

(c) providing a D.C. electric motor or other electrical device to harness the electric energy produced; and

(d) heating the thermoemissive material to cause it to emit electrons into the surrounding air, thereby drawing replacement electrons from the earth's surface through the conductor to the thermoemissive material.

2. An apparatus for generating an electric current and power, comprising:

(a) a thermoemissive material positioned above the surface of the earth;

(b) a conductive path between the earth's surface and the thermoemissive material;

(c) a direct-current electric motor or other electrical device, operatively positioned to harness the electric energy produced;

(d) an arrangement for heating the said thermoemissive material, so that electrons are emitted from the latter; and, if an electric motor is chosen in (c) above,

(e) a generator (optional) for generating electricity from the power provided by said electric motor.

3. The apparatus of claim **2** wherein said thermoemissive material is provided as a plaque.

4. The apparatus of claim **2** wherein said thermoemissive material is a sintered or unsintered ceramic material, or any metal or metallic alloy, or any combination thereof, operating at any state of interest.

5. The apparatus of claim **4** wherein said thermoemissive material is selected from the group consisting of BaO, SrO, Mo-sintered BaO/SrO, Ni/BaS, Pt/BaS, Ni, Pt, Sr, Mo, K, Na, Ba, S, Cs, Ca, Li and Fr, or combinations thereof.

METHOD AND APPARATUS FOR A WIRELESS POWER SUPPLY

This application is a continuation application of application Ser. No. 10/966,880 filed on Oct. 15, 2004, now U.S. Pat. No. 7,027,311.

The nonprovisional application designated above, namely application Ser. No. 10/966,880, filed Oct. 15, 2004, claims the benefit of U.S. Provisional Application No.:

APPLICATION NO. 60/511,860
FILING DATE Oct. 17,2003

FIELD OF THE INVENTION

The present invention is related to the retrieval of radiated electrical energy. More specifically, the present invention is related to the retrieval of radiated electrical energy that is optimized for any given portion of the RF spectrum using a plurality of taps.

BACKGROUND OF THE INVENTION

In the operation of the invention, ambient RF and generated RF signals provide a source of potential energy that can be gathered, stored and supplied to a multitude of devices requiring electrical energy or that can restore energy lost by a discharged source.

Traditional RF receiving devices utilize an antenna to capture a narrow band of frequencies within the RF spectrum, whereby the collection of RF frequencies is then filtered, or tuned, to a specific frequency(s) for the purposes of maximizing the signal being transmitted within the chosen frequency (s). The potential energy contained in the signal is then used for its intended purpose, such as audio, video or data processing. These RF receiving devices have focused on maximizing selectivity of the frequency in order to isolate and to be coherent without interference from other sources.

SUMMARY OF THE INVENTION

The present invention pertains to an apparatus for a wireless power supply. The apparatus comprises means for receiving a range of RF radiation across a collection of frequencies, preferably at a same time. The apparatus comprises means for converting the RF radiation across the collection of frequencies, preferably at a same time into DC.

The present invention pertains to a method for a wireless power supply. The method comprises the steps of receiving a range of RF radiation across a collection of frequencies, preferably at a same time. There is the step of converting the RF radiation across the collection of frequencies, preferably at a same time into DC.

BRIEF DESCRIPTION OF THE DRAWINGS

In the accompanying drawings, the preferred embodiment of the invention and preferred methods of practicing the invention are illustrated in which:

FIG. **1** is a schematic representation of a preferred embodiment of an apparatus of the present invention.

FIG. **2** is a schematic representation of a preferred embodiment of an apparatus of the present invention optimized for medium wave bandwidth RF energy retrieval, collection and storage.

FIG. **3** is a block diagram of the apparatus of the present invention.

DETAILED DESCRIPTION

Referring now to the drawings wherein like reference numerals refer to similar or identical parts throughout the several views, and more specifically to FIG. **1** thereof, there is shown an apparatus **10** for a wireless power supply. The apparatus **10** comprises means **12** for receiving a range of RF radiation across a collection of frequencies, preferably at a same time. The apparatus **10** comprises means **14** for converting the RF radiation across the collection of frequencies, preferably at a same time into DC.

Preferably, the converting means **14** includes an absorbing mechanism **16** which is resonant for a desired band of RF spectrum. The absorbing mechanism **16** preferably includes an inductor **18** which is resonant for the desired band of RF spectrum. Preferably, the converting means **14** includes a plurality of taps **20** placed at points along the inductor **18** to access the RF energy.

The tap points preferably are calculated by matching the inductor's **18** impedance to the desired band of RF spectrum. Preferably, the receiving means **12** includes an antenna **22**. The converting means **14** preferably includes a rectifying mechanism **24** which rectifies the RF energy and converts it into DC voltage. Preferably, the rectifying mechanism **24** includes a plurality of diodes **26** at each tap point which rectifies the RF energy and converts it into DC voltage.

The apparatus **10** preferably includes a storage device **28** for storing the DC voltage. Preferably, the antenna **22** impedance is matched 1:1 with the inductor **18** impedance. The RF spectrum preferably is between 60 Hz to 28 gigahertz.

The present invention pertains to a method for a wireless power supply. The method comprises the steps of receiving a range of RF radiation across a collection of frequencies. There is the step of converting the RF radiation across the collection of frequencies, preferably at a same time into DC.

Preferably, the converting step includes the step of absorbing the energy. The absorbing step preferably includes the step of absorbing the energy with an inductor **18**. Preferably, the converting step includes the step of accessing the absorbing energy with a plurality of taps **20** on the inductor **18**. There is preferably the step of matching the inductor's impedance to a desired RF range.

Preferably, the converting step includes the step of rectifying energy available at each tap and converting it into DC voltages. The rectifying step preferably includes the step of rectifying the energy available at each tap and converting it into DC voltages with diodes **26**. Preferably, the converting step includes the step of summing the DC voltages. The summing step preferably includes the step of adding the DC voltages among a series capacitor integrator. Preferably, there is the step of storing the summed DC voltages. There is preferably the step of using the stored DC voltages.

A method and apparatus **10** for retrieval of radiated electrical energy is described herein. The radiated energy to be captured is being transmitted in the portion of the electromagnetic spectrum sometimes referred to as RF, or Radio Frequency. The primary purpose of the method and apparatus **10** described herein, is to receive RF energy and convert the energy into a usable form of power. The method and apparatus **10** does not discern or interpret individual signals or frequencies. It is designed to absorb and convert signal, carrier and any associated interference for a chosen band or range of frequencies into reusable power.

In contrast, to traditional RF receiving devices, this methodology and apparatus **10** avoids selectivity. It has the unique characteristic of accepting broad ranges of the RF spectrum as a collection of frequencies. Each collected range of frequencies is then rectified, or converted, as a whole into a single voltage. Preferably, at the same time of RF absorption, the resultant voltage is generated. The apparatus **10** makes no attempt to tune for any specific frequency or signal. Each voltage, which is gathered from a given range of frequencies, is then added together and made available to power a device directly, to be stored, or to supply energy to a recharging apparatus. As is implicit from the aforementioned description, preferably, the apparatus **10** receives the RF radiation across the collection of frequencies at the same time.

The radiated electrical energy, to be utilized by the circuit, can be in the form of a wide range of the RF spectrum. Some examples of ambient RF sources can include, but are not limited to: Very Low Frequency—VLF (Maritime/Aeronautical Mobile), Medium Frequency—MF (AM Radio Broadcast), High Frequency—HF (Shortwave Radio Broadcast), Very High Frequency—VHF (TV and FM Radio Broadcast), Ultra High Frequency—UHF (TV, HDTV, PCS, WiFi) and certain Microwave transmissions. In addition, the apparatus **10** allows for the reception of dedicated RF transmission that are generated and broadcast for the specific purpose of transmitting power to the apparatus **10** for absorption, collection and utilization. In this case, it is not necessary for the dedicated RF transmission to contain a specific signal or data that needs to be interpreted for ancillary purposes such as audio/video or data reception and interpretation.

Using the technique described herein, one can design and create an apparatus **10** that is optimized for any given portion of the RF Spectrum. The necessary electrical and magnetic characteristics of the apparatus **10** components will vary depending on the chosen portion of the spectrum. Because of this, it is impractical to create one single apparatus **10** to cover the entire RF spectrum. However, it is possible to create individual apparatus **10**, each designed for a given RF band, and combine both the apparatus **10**, their outputs for maximum power efficiency.

A portion of a selected RF frequency band is intercepted by an antenna **22** placed in the field of emitted energy. The antenna **22** receives energy, in accordance with its design efficiency, and directs it into a system where it is absorbed, rectified, summed and delivered for use or storage.

RF Energy→Antenna→
[Absorbed→Rectified→Integrated→Delivered]
→Used

RF signals striking an antenna **22** are fed into an inductor (L), which is resonant for the desired band of RF spectrum. Note: In areas with a high concentration of RF energy, there is no need to attach an antenna **22**. The absorbed RF energy, consisting of fundamental, harmonic, inter-harmonic and standing waves is accessed via taps **20** (T**1**-Tx) on the inductor **18** which are placed at points along the inductor **18**. A key characteristic of this device is that a capacitor-less front-end allows for the inductors' wide bandwidth and maximum admittance of the incoming RF energy. The tap points are calculated by matching the inductor **18** section's impedance to the desired RF range.

The resultant RF energy, available at each tap point, is rectified by a device, such as diodes **26** (D**1**-Dx), and converted into DC Voltages. The individual rectified voltages are spread among a series capacitor integrator consisting of capacitors (C**1**-Cx). This broadband approach allows maximum energy to be spread among the series capacitor stack.

The sum of the voltages available from C**1**-Cx is stored in any storage device **28** such as a capacitor or group of capacitors Cs (s**1**-sx) and made available for immediate use, or to supply electronic device(s) requiring intermittent power. The electrical characteristics of the storage devices or capacitors, the configuration and actual number of storage devices is dependent on the voltage and power requirements of the device the apparatus **10** is delivering power to. (See Figure One)

Although not considered part of the apparatus **10**, the antenna **22** is an integral component of any practical device utilizing the method and apparatus **10** described. The key characteristics of the antenna **22** would be that it is capable of wide band reception, optimized for the chosen bandwidth, and takes into consideration the necessary effective area to support the power requirements of the target device.

Ideally, the antenna **22** impedance is matched 1:1 with the inductor **18** impedance of the apparatus **10**.

Note: In areas with a high concentration of RF energy, there is no need to attach an antenna **22** to the apparatus **10**.

Inductor **18**:

The characteristics of the inductor **18** is dependent on the chosen bandwidth of frequencies to be collected and utilized. The ideal inductor **18** should be constructed so that the mid point of total inductance would be resonant at the center frequency of the chosen RF segment or spectrum.

Multiple taps **20** provide fundamental and inter-harmonic output voltages from the selected band segments of radio frequency energy.

For example, a medium wave circuit (FIG. **2**), utilizing an antenna **22** impedance of 375 ohms, into an inductive circuit with 375 ohms of reactance, with a center frequency of 1.2 MHz would require an inductance of 100 uH. The effective bandwidth would be approximately 2 MHz wide. (−3 db down at each end of the band).

The inductor **18** can be calculated using the following standard resonance formula (Formula 1):

L=(*d* squared times *n* squared) divided by (18 times *d* plus 40 times *j*)

Where

L=inductance in micro-henrys.
d=conductor diameter in inches.
j=conductor length in inches.
n=number of conductor iterations.

Using similar formulae, the required inductance can be re-calculated for henrys, milli-henrys, pico-henrys and nano-henrys. ie. VLF, LF, MW, HF, VHF, UHF and Microwave frequency band segments.

Utilizing a capacitor-less front-end insures the inductors' wide bandwidth, and maximum admittance to the incoming RF energy.

Taps **20**:

Taps **20** are to be constructed and placed at points along the inductor **18**. Each tap provides an individual output voltage into the rectifying portion of the apparatus **10**.

The number of taps **20** from the inductor **18** can be calculated by the following formula (Formula 2):

Tn=Bw times pi

Where

Tn=Total number of taps.
Bw=Effective Bandwidth of inductor (in Megahertz).
Pi=3.1416

The default position of each tap on the inductor **18** is equidistant along the inductor **18**. Tap positions can also be calculated for optimum output voltage. When calculating the taps **20**, one must take into consideration known frequencies within the chosen band segment that contain higher RF energies, And using a standard resonance inductance formula (1) each individual tap can be calculated for the required frequency and optimum voltage output.

Rectifiers:

The RF energy available at each tap is converted to DC voltage via a rectifying device. The type of rectifying device to be used is dependent on the chosen frequency band, and includes crystal, germanium, silicon and any other types.

Integrator:

A voltage integrator is composed of capacitors C**1**-Cx. The values of these capacitors are dependent on the chosen frequency band, the unique characteristics of the rectifiers and the load imposed by the Storage stage. The reactance of this circuit varies greatly, even during normal operation. However, one can use a standard formula for capacitive reactance as a starting point for preliminary calculations:

$$Xc=1/(2*pi*F*C)$$

Where
Xc=Capacitive reactance in ohms
C=Capacitance in Microfarads.
F=Frequency in Hertz.
Pi=3.1416

Storage:

Storage component(s) are determined by the power requirements of the attached device(s), and the available RF energy absorbed by the inductor (L).

Using a Medium Wave example, a 2,200 micro-farad electrolytic capacitor is used as storage.

Sample Apparatus 10: Medium Wave (AM) Wireless Power Supply

A device has been constructed, using the method stated above, which uses the ambient (existing) AM Broadcast band of the RF spectrum as its source of energy. The device's primary purpose is to optimize the energy absorbed, collected and converted to reusable power.

The size and characteristics of the antenna **22** required for the circuit to operate are not considered a design requirement for the apparatus **10**. The antenna **22** needed to obtain sufficient energy to charge a storage device **28** in a typical urban area with several AM radio stations, would be similar to one used for a standard AM radio. In areas where there is a higher concentration of RF energy, the apparatus **10** itself, without an antenna **22**, is sufficient to develop stored power.

The inductor **18** is in the form of an air coil comprised of enameled #28 gauge wire wound onto a 2" form. The coil is a continuous tightly wound wire with taps **20** placed every twenty turns with a total of six taps **20** available (T**1**-T**6**). The top of the coil is where the antenna **22** is connected. The bottom of the coil is connected to ground.

Germanium diodes (IN34A) (D**1**-D**6**) are connected to each tap on the coil. The series capacitor integrator (C**1**-C**6**) is constructed as illustrated with the C**6** attached to ground. C**1**-C**6** are poly capacitors with a 0.068 uF rating. The power storage device **28** utilized in this sample apparatus **10**, C7, is a 2200 uF electrolytic capacitor.

Very wide band operation can be utilized by coupling multiple instances of the Broadband Wireless Power Supply together.

For Example:

A BWPS circuit designed and constructed (see design considerations) for a Very Low Frequency wave segment (60 Hz center frequency), can be coupled into another BWPS circuit designed and constructed (see design considerations) for an Ultra High Frequency wave segment (5 GHz center frequency). The outputs of each individual circuit connect (via another integrator circuit) into a common storage device **28** (i.e., capacitor) to "pool" collected and converted RF energy together. This technique can be repeated for any or all segments of the energy spectrum.

Although the invention has been described in detail in the foregoing embodiments for the purpose of illustration, it is to be understood that such detail is solely for that purpose and that variations can be made therein by those skilled in the art without departing from the spirit and scope of the invention except as it may be described by the following claims.

What is claimed is:

1. An apparatus, comprising:

means for receiving RF radiation within a plurality of frequency bands; and

means for converting separately the received RF radiation associated with each of the plurality of frequency bands into DC, the converting means includes an inductor and at least three taps, each tap from the at least three taps being placed at a unique point along the inductor to access an energy associated with the RF radiation.

2. An apparatus as described in claim **1** wherein the inductor includes one or more portions, each portion of the inductor is uniquely associated with one frequency band from the plurality of frequency bands, each portion of the inductor has a resonant frequency within that frequency band.

3. An apparatus as described in claim **2** wherein the tap points are calculated based on the resonant frequency for each portion of the inductor.

4. An apparatus as described, in claim **1** wherein the receiving means includes an antenna.

5. An apparatus as described in claim **1** wherein the converting means includes a rectifying mechanism which rectifies the energy associated with the received RE radiation to produce rectified energy and converts the rectified energy into a DC voltage.

6. An apparatus as described in claim **5** wherein the rectifying mechanism includes a diode at each tap point to rectify the energy associated with the received RF radiation into the DC voltage.

7. An apparatus as described in claim **5** further comprising a storage device for storing the DC voltage.

8. A method, comprising:

receiving RF radiation within a plurality of frequency bands at a single antenna;

separating the received RE radiation into a plurality of portions of the received RE radiation independent of a capacitor, each portion from the plurality of portions of the received RE radiation uniquely associated with a frequency band from the plurality of frequency bands; and

converting separately the plurality of portions of the received RE radiation into DC.

9. A method as the described in claim **8** wherein the converting includes absorbing an energy associated with the received RF radiation.

10. A method as described in claim **9** wherein the absorbing includes absorbing the energy with an inductor.

11. A method as described in claim **10** wherein the converting includes accessing the absorbed energy with a plurality of taps on the inductor.

12. A method as described in claim **11** wherein the converting includes rectifying the energy associated with each tap to produce rectified energy and converting the rectified energy associated with each tap into a DC voltage.

13. A method as described in claim **12** wherein the rectifying includes rectifying the energy associated with each tap to produce rectified energy and converting the rectified energy associated with each tap into the DC voltage with a diode.

14. A method as described in claim **13** wherein the converting includes adding the DC voltage associated with each tap from the plurality of taps into a single DC voltage.

15. A method as described in claim **14** wherein the adding includes integrating the DC voltage associated with each tap from the plurality of taps with a series capacitor integrator.

16. A method as described in claim **14** further comprising storing the single DC voltage.

17. An apparatus, comprising:

means for receiving a range of RF radiation across a collection of frequencies; and

means for converting RF radiation across the collection of frequencies into DC, including multiple taps to access the PT radiation across the collection of frequencies.

18. An apparatus, comprising:

means for receiving a range of RF radiation across a collection of frequencies with a single antenna; and

means for converting RF radiation across the collection of frequencies from the single antenna into DC, the converting means includes an inductor that is resonant for a desired band of RF spectrum, the inductor having a plurality of taps placed at points along the inductor to access the RE energy.

19. A method, comprising:

receiving a range of RF radiation across a collection of frequencies at a single antenna;

converting the RF radiation received at the single antenna across the collection of frequencies into DC by absorbing the energy with an inductor; and

accessing the absorbed energy with a plurality of taps on the inductor.

20. A method, comprising:

receiving radiation within an RF spectrum band via a single antenna, a first portion of the received radiation being associated with a first portion of the RF spectrum band, a second portion of the received radiation being associated with a second portion of the RF spectrum band different than the first portion;

converting separately the received radiation from each of the first portion of the RF spectrum band and the second portion of the RF spectrum band into a DC voltage; and

combining the DC voltage associated with the first portion of the RF spectrum band and the DC voltage associated with the second portion of the RE spectrum band.

(57) **ABSTRACT**

A mechanism to tap an electrical source which uses an aircraft (preferably a lighter than air balloon) tethered by a conductive line. The conductive line is extended/withdrawn by a winch motor to adjust the altitude of the aircraft. The conductive line is isolated from the ground and an electrical conductor is connected to the conductive line and to an electrical load. In this manner, static electricity generated in the atmosphere is gathered for use.

ATMOSPHERIC ELECTRICAL GENERATOR

BACKGROUND OF THE INVENTION

This invention relates to the production of electrical energy and more particularly to the production of electrical energy from the atmosphere.

Everyone is familiar with Benjamin Franklin's kite experiment of 1752. Using a kite whose string had become wet, negative charges from the passing clouds flowed into the string, down to the suspended key, and then into a Leyden jar via a thin metal wire. Franklin was protected by a dry silk string; but, when Franklin's knuckle came too close to the key, he received a strong shock. Fortunately, Benjamin Franklin was not killed, others who tried this same experiment were not so lucky.

Since then, the formation of lightning has remained something of a mystery. Lightning bolts are triggered when a negatively charged cloud base induces a positive charge from the ground, thereby forming a "pathway" for the discharge of the collected electrical energy.

Lightning travels up to 60,000 miles per hour with a flash that is brighter than ten million 100-watt lightbulbs. This wattage is as much power as is produced by all of the electricity plants in the United States and with a voltage of up to 300 million volts.

It is this very fact, the power within lightning is immense, that has prevented any successful collection of the electrical energy from lightning. The electricity in lightning is far too extreme for current technology to harness.

While lightning has attracted a energy starved industrial world, no one has developed any technique to harness this naturally occurring electrical source.

It is clear there is a continuing need for an electrical source other than carbon-based fuels and that the naturally occurring electricity in the atmosphere is being ignored.

SUMMARY OF THE INVENTION

The invention is a mechanism which taps into the naturally occurring static electricity in the atmosphere. Whereas heretofore, the attempt to garner electricity from the atmosphere has focused exclusively on capturing lightning, the present invention syphons off the static electricity which is generated from any agitated air and avoids lightning.

Lightning is only the final discharge of the static electricity, whether that lightning is intra-cloud lightning, cloud-to-ground lightning, or inter-cloud lightning. Other types of final discharges are known as heat lightning, summer lightning, sheet lightning, ribbon lightning, silent lightning, ball lightning, bead lightning, elves, jets, and sprites. Well before these discharges are observed, as the atmosphere becomes agitated by wind or thermal activity, static electricity is being generated.

The present invention recognizes that this static electricity is being formed and creates a mechanism to capture it.

The mechanism of this invention utilizes an aircraft such as a lighter than air balloon. While the preferred embodiment uses a foil balloon, a variety of other aircraft are obvious to those of ordinary skill in the art, including, but not limited to: gliders, rubber balloons (such as weather balloons), biaxially-oriented polyethylene terephthalate polyester film balloons, and latex balloons.

Within this discussion, the balloon is referenced, but, the invention is not intended to be limited solely to balloons.

The balloon is sent aloft and is tethered by a conductive line. In this context, the conductive line may be any obvious to those of ordinary skill in the art. For the preferred embodiment, the conductive line is a generically referred to as a "poly-rope" and is commercially available through a variety of sources. A suitable conductive line is described in U.S. Pat. No. 5,203,542, entitled "Apparatus for Improved Electric Fence Wire Construction for use with Intensive Grazing" issued Apr. 20, 1993, to Coley, et al. and incorporated hereinto by reference.

The conductive line is played out of a winch to control the altitude of the balloon. The motor controlling the winch is able to reverse direction to both extend and withdraw the conductive line which is wrapped around a spool on the winch. The winch/spool combination are part of a base unit.

In some embodiments of the invention, the spool is constructed of rubber so as to insulate the conductive line from the winch assembly. In this embodiment, only the conductive line is charged by the atmospheric static electricity while the winch remains neutral.

In yet another embodiment, the winch/spool are part of a base unit which is itself isolated from the ground by an insulator. In this embodiment, the entire base unit is charged by the atmospheric static electricity.

A conductor, such as an insulated wire, is electrically connected to the conductive line. In one embodiment, where the conductive line is electrically isolated from the spool and winch motor, the conductor is connected to the conductive line. In the embodiment where the conductive line is electrically connected to the base unit, then the conductor is connected anywhere on a metallic base unit.

The other end of the conductor is connected to a load. The load in this case can be any of a variety of electrical loads well known to those of ordinary skill in art, including, but not limited to a motor, a battery system, or the electrical grid for the system.

In the preferred embodiment, a sensor array is used to monitor the activities both at the base unit (such as electrical flow within the conductor) and in the surrounding locale.

A sensor monitoring the electrical flow (i.e. voltage and/or current) within the conductor is used to monitor the electrical activity within the conductor.

In the preferred embodiment, a lightning sensor monitors for lightning activity within the locale. As noted earlier, the electrical characteristic of lightning is so extreme that ideally this discharge is avoided as it might damage the mechanism of this invention.

The sensor array is utilized by a controller, such as microprocessor, programmed to operate the mechanism as outlined herein.

The controller operates the winch motor to extend or withdraw the conductive line and by extension the altitude of the balloon. The controller is programmed to operate the winch by monitoring the electrical characteristics of the conductor and adjusting the balloon's altitude to maintain these characteristics within the conductor within a preset range.

This preset range is established either in the base programming of the controller or is established by an operator of the system.

As example, by controlling the amount of current being withdrawn from the atmosphere, the mechanism operates within a safe range and also provides a relatively stable current flow from which a variety of activities can take place (such as DC-AC conversion).

The controller also utilizes the lightning sensor to protect the mechanism from a lightning strike. Should lightning be detected within a pre-determined range (as established by the software or defined by an operator), then the balloon is pulled down to minimize the risk of damage from a lightning strike.

The invention, together with various embodiments thereof will be more fully explained by the following description of the accompanying drawings.

DRAWINGS IN BRIEF

FIG. **1** diagrams the preferred embodiment of the invention.

FIG. **2** illustrates the collection of the negative charged particles in the atmosphere.

FIG. **3** is a flow-chart of the operation of the controller for the preferred embodiment of the invention.

FIGS. **4**A, **4**B, and **4**C are electrical schematics for handling the static charge from the atmosphere.

FIG. **5** illustrates a conductive line used in the preferred embodiment of the invention.

FIGS. **6**A and **6**B illustrate an alternative conductive line creating an ionized pathway for the flow of the static charges from the atmosphere.

FIG. **7** illustrates the controller of an alternative embodiment and the associated safety devices.

FIGS. **8**A and **8**B illustrate two embodiments of enhanced electrical collection leads.

DRAWINGS IN DETAIL

FIG. **1** diagrams the preferred embodiment of the invention.

Balloon **10** is an aircraft which, in this illustration, is a lighter than air balloon. Wings **10**A, extending from the body of balloon **10**, provide additional lift in air flow **18**. Tail **10**B helps to stabilize balloon **10**.

Balloon **10** is tethered to the ground via conductive line **12**. As noted earlier, a variety of configurations and materials are available to serve as conductive line **12**. In this illustration, a poly-wire is used Poly-wire is commercially available through a variety of vendors, including, but not limited to: Jeffers Livestock and Zareba Systems, Inc, of Ellendale, Minn.

In this embodiment, located proximate to balloon **10**, is an electrical collection enhancement lead **11** which assists in the collection of the static electrical charge in the atmosphere. Electrical collection enhancement lead **11** is configured to attract the static charge and conduct the charge into the conductive line **12**.

The electricity flows down the conductive line into spool **13**, where the conductive line **12** is collected and either withdrawn or dispensed through operation of winch motor **14**.

Winch motor **14** and spool **13** are mounted onto base unit **16** which is electrically isolated from ground **7** using insulator **17**. Note, in this embodiment of the invention, when electricity is being collected from the atmosphere, the entire base unit **16** becomes charged. In another embodiment of the invention, spool **13** is constructed of rubber, thereby preventing base unit **16** from becoming charged, thereby restricting the charging from the atmosphere to only conductive line **12**.

In this embodiment, conductor **6** is connected to base unit **16** (since the entire base unit **16** is charged and the base unit is metallic) to communicate the electrical current to load **5**. Conductor **6** is ideally an insulated wire.

The electrical current through conductor **6** is measured using sensor **8**.

In the alternative embodiment discussed above, where only the conductive line **12** is charged, then conductor **6** is connected to conductive line **12**.

Controller **15**, located in this embodiment on base unit **16**, operates winch motor **14** in response to signals from sensor **8** (measuring the current being discharged to load **5**) to maintain the current flow within a pre-defined range. As the current flow diminishes, then the conductive line **12** extended from spool **13** to increase the altitude of balloon **10** to that more static charge from the atmosphere is gathered; as the current flow falls exceeds a preset level, conductive line **12** is withdrawn onto spool **13** to decrease the static charge being collected from the atmosphere.

The range of current flow through conductor **6** is ideally set by the program, although some embodiments of the invention permit an operator to establish this range of operation.

In an alternative embodiment, the sensor monitoring conductor **6** monitors the voltage therein.

In the preferred embodiment of the invention, controller **15** is also equipped with a lightning sensor **19**. In this embodiment, when lightning is sensed within a preset range, then substantially all of conductive line **12** is wound onto spool **13** to pull balloon **10** near the ground and protect the entire mechanism from being damaged from a lightning discharge.

In the preferred embodiment, the "safe" distance form lightning is set in the programming of controller **15** and is ideally two miles; other embodiments permit the operator to "safe" distance.

There are a variety of lightning sensors well known to those of ordinary skill in the art, including, but not limited to those described in: U.S. Pat. No. 7,016,785, entitled "Lightning Detection" issued to Makela, et al. on Mar. 21, 2006; U.S. Pat. No. 6,829,911, entitled "Lightning Detection and Prediction Alarm Device" issued to Jones, et al. on Dec. 7, 2004; U.S. Pat. No. 7,200,418, entitled "Detection of Lightning" issued to Karikuranta, et al. on Apr. 3, 2007; and U.S. Pat. No. 6,961,662, entitled "Systems and Methods for Spectral Corrected Lightning Detection" issued to Murphy on Nov. 1, 2005; all of which are incorporated hereinto by reference.

In another embodiment of the invention, controller **15** is not located on base unit **16**, rather it is remote and communicates its control signals to winch motor **14** using radio waves.

FIG. **2** illustrates the collection of the negative charged particles in the atmosphere.

Static charges **23** are generated in the atmosphere by agitated air. These static charges are often collected at the bottom of clouds, but exist in other environments as well.

Balloon **21** is extended into this strata of static charges **23** which are then attracted to conductive line **12** to flow to base unit **22** and then onto load **5**.

By increasing or decreasing the altitude of balloon **21** (defined by the length of the extended conductive line **12**), conductive line **12** is selectively exposed to varying densities and levels of the static charge strata, and by extension, the current flow or voltage is increased or decreased.

FIG. **3** is a flow-chart of the operation of the controller for the preferred embodiment of the invention.

Once the program starts **30**, the lightning sensor is checked to determine if lightning has occurred within the unsafe range **31**A, if it has, then the balloon is lowered **32**A, and the program continues monitoring the status of lightning until no lightning is detected.

When the lightning status is acceptable, then the current within the conductor is checked to see if the current is within the prescribed range **31**B. If the current is acceptable (within range) the program returns to check the lightning status **31**A; otherwise a determination is made to see if the current is above the prescribed range **31**C.

If the current is above the prescribed range, then the altitude of the balloon is withdrawn a set amount **32**B (ideally twenty-five feet) and the program loops back to see if the current is within range **31**B.

If the current is below the prescribed range, then the altitude of the balloon is extended a set amount **32**C (ideally twenty-five feet) and the program loops back to see if the current is within range **31**B.

In this manner of feed-back and minor adjustments in the altitude of the balloon, the current is maintained within a prescribed range which can be handled by the downstream electrical system.

As noted earlier, some embodiments of the invention monitor the voltage instead of the current.

FIGS. **4**A, **4**B, and **4**C are electrical schematics for handling the static charge from the atmosphere.

By maintaining the voltage being collected in a prescribed range, an electrical conversion system is easily designed. While FIGS. **4**A, **4**B, and **4**C illustrate some electrical configurations, those of ordinary skill in the art readily recognize a variety of other configurations which will serve the same function.

Referencing FIG. **4**A, Direct Current In (DC IN) **40** is buffered by a gang of capacitors **41** before being communicated to a DC/AC converter **42**. The DC/AC converter converts the direct current into a an alternating current suitable for placement over an existing electrical grid **43** such as normally found from a power-plant.

Those of ordinary skill in the art readily recognize a variety of DC/AC converters, including, but not limited to: U.S. Pat. No. 7,394,671, entitled "Controller IC, DC-AC Conversion Apparatus, and parallel running system of DC-AC Conversion Apparatuses" issued to Fukumoto, et al. on Jul. 1, 2008; and, U.S. Pat. No. 7,330,366, entitled "DC-AC Converter" issued to Lee, et al. on Feb. 12, 2008; all of which are incorporated hereinto by reference.

FIG. **4**B illustrates an electrical arrangement suitable for use in charging a battery. DC IN **40** is buffered by capacitor bank **41** before entering into a step down transformer **43**. Step down transformer **43** reduces the voltage so that the voltage can safely be introduced into battery **44** which is connected to ground **45** at the battery's other pole.

Those of ordinary skill in the art readily recognize a variety of batteries which will work in this capacity, including, but not limited to those described in: U.S. Pat. No. 7,378,181, entitled "Electric Storage Battery Construction and Manufacture" issued to Skinlo on May 27, 2008; U.S. Pat. No. 7,388,350, entitled "Battery with Electronic Compartment" issued to Wright on Jun. 17, 2008; U.S. Pat. No. 7,397,220, entitled "Connection Member and Battery Pack" issued to Uchida, et al. on Jul. 8, 2008; and, U.S. Pat. No. 7,375,492, entitled "Inductively Charged Battery Pack" issued to Calhoon, et al. on May 20, 2008; all of which are incorporated hereinto by reference.

In FIG. **4**C, DC IN **40** is fed into an adjustable rheostat **46** which is controlled by the controller so that the DC OUT **47** falls within a specified range.

FIG. **5** illustrates a conductive line used in the preferred embodiment of the invention.

This type of conductive line is commonly called poly-wire and consists of multiple interwoven strands of plastic **50**A and **50**B woven into a cord or rope arrangement having intertwined therein exposed metal wires **51**A and **51**B. While this illustration shows two plastic strands and two metal wires, any number of possible combinations is possible.

The exposed metal wires **51**A and **51**B attract the atmospheric static charge and transmit the charge down to the base unit (not shown).

FIGS. **6**A and **6**B illustrate an alternative conductive line creating an ionized pathway for the flow of the static charges from the atmosphere.

This conductive line utilizes a tube **60** having an outer layer **62** of PET Film (Biaxially-oriented polyethylene terephtalate polyester film) which provides exceptionally high tensile strength and is chemically and dimensionally stable. The tube has an ideal diameter of between two and three inches.

An interior metal coating **61** provides an initial conduit for the flow of static charge. The static charge through the metal forces the tube to expand due to the repulsion experienced by like charges. Further, the flow of electricity causes the interior of the tube **60** to become ionized to provide an additional pathway for the atmospheric static charges to the base unit (not shown).

Because outer layer **62** provides a gas barrier, the resulting ionization is not dissipated by air currents, thereby providing a highly stable pathway.

FIG. **7** illustrates the controller of an alternative embodiment and the associated safety devices.

In this embodiment, controller box **70**, resting on insulating pad **72**, is in communication with the sensors as described above. Using the input from these sensors, when there is flow of electricity through the base unit, warning flashing light **71** is illuminated. To electrically neutralize the mechanism, switch **73** is activated to pass any existing current into the ground **74**.

FIGS. **8**A and **8**B illustrate two embodiments of enhanced electrical collection leads.

Referencing FIG. **8**A, enhanced electrical collection lead **82** is a wire mesh which is in electrical communication with conductive line **81** and balloon **80**. Because of the significant amount of metal exposed by enhanced electrical collection lead **82**, more static electricity from the atmosphere is drawn to the collection lead **82**, and then down conductive line **81** to the base unit (not shown).

Conductive lead **82** is positioned proximate to balloon **80**.

In FIG. **8**B, poly-wire **83** has enhanced electrical collection leads **84** wrapped therearound. Collection leads **84** have pointed ends **85**A and **85**B which have a propensity to attract more electricity than rounded ends do.

It is clear from the foregoing that the present invention captures an entirely new source of electrical energy.

What is claimed is:

1. A mechanism to tap an electrical source comprising:

a) a lighter than air balloon suspended in the atmosphere;

b) a base unit having a spool of conductive line on a winch motor, one end of said conductive line secured to said lighter than air balloon, a portion of said conductive line collecting electricity in the atmosphere, said winch motor capable of selectively extending or withdrawing said conductive line from said spool;

c) an insulator electrically isolating said conductive line from ground;

d) a conductor having a first end electrically connected to said conductive line and a second end electrically connected to a load being powered by collected electricity from said conductive line;

e) an electrical flow sensor monitoring electrical flow through said conductor and generating an electrical flow indicia indicative of said electrical flow in said conductor; and,
